Traditional Oracle dSource snapshots require some recovery during provisioning. By configuring validated sync for Oracle, the Delphix Engine selects a compatible Oracle installation and applies the recovery necessary to provision a snapshot immediately after each SnapSync. Snapshots that have been through this validated sync process step do not require recovery during provisioning.

 The Delphix Engine may be unable to perform validated sync on a physical standby database in Real-Time Apply mode. This is because the standby may apply changes before copying the logs that contain those changes. Without the logs necessary to perform recovery, validated sync cannot be executed. However, you can still provision the snapshot when the archive logs become available on the standby.

### Prerequisite: designating a staging host

In order to validate an Oracle dSource snapshot after a sync, the Delphix Engine requires a host with an Oracle installation that is compatible with the dSource. This machine is known as the **staging** host. You must explicitly designate which machines you want the Delphix Engine to use as staging hosts. All machines that have been marked as staging hosts are added to a pool. During sync validation, the Delphix Engine will select a compatible host from the pool, export the requisite archived redo logs and data files, and execute Oracle media recovery on the host. Follow these steps to designate a staging host.

1. Log into the Delphix Management application.
2. Click **Manage**.
3. Select **Environments**.
4. In the **Environments** panel, select the environment you want to designate as staging.
5. Select the **Databases** tab.
6. Scroll down to the installations you want to designate as staging and edit the **Installation Details** by clicking on the **pencil** icon.
7. Select the **Use as staging** checkbox.
8. Select the green checkmark to confirm your change.

To configure validated sync for multiple dSources with different Oracle versions, you must designate a compatible staging source for each. If multiple compatible staging sites exist, the Delphix Engine will select one at random.

 The validated sync process will consume some resources on the staging host when snapshots are taken. Designating a performance-critical host as a staging host is not recommended.

 The default OS user for the staging host must have access to the Oracle installation that will be used to perform recovery during validated sync.

 **Oracle pluggable database**  
Validated sync for Oracle pluggable databases is not supported in this release.

## Enabling validated sync

Oracle validated sync can be enabled at link time or on any existing dSource. When adding the dSource (at link time), in the Data Management tab, select Show Advanced, and select the Enable checkbox for Validated Sync.

For an existing dSource:

1. Log into the Delphix Management application using **Delphix Admin** credentials.
2. Click **Manage**.
3. Select **Datasets**.
4. In the **Datasets** panel, select the dSource for which you want to enable sync validation.
5. Select the **Configuration** tab and then select the **Data Management** sub-tab.
6. Select the pencil icon located next to the **VALIDATED SYNC CONFIGURATION**.
7. Select one of the following from the **Validated Sync Mode** drop-down list:
  - a. Transaction Log
  - b. Full or Differential
  - c. Full
  - d. None

8. Select the checkmark to confirm your change.

## Linking Oracle physical standby databases

This topic describes special considerations for linking Oracle physical standby databases.

The Delphix Engine supports linking both physical and logical standby databases. In previous versions of the Delphix Engine, limitations were placed upon support for Oracle RAC physical standby databases in Real-Time Apply mode. In version 3.0 of the Delphix Engine, these restrictions were lifted.

**Using block change tracking (BCT) on a physical standby database**

In general, Delphix recommends enabling Block Change Tracking (BCT) on a primary or standby source database. See Physical Standby Database Support Matrix below for restrictions on enabling BCT on a standby database.

BCT is available from Oracle release 11.1.0.6 onward for physical standby databases **only** if they are licensed for the Active Data Guard option.

- Release 11.1.0.6 is unstable for the BCT on physical standby feature
- Release 11.1.0.7 requires a patch for Oracle bugs 7613481, 9068088
- Release 11.2.0.2 requires patches for Oracle bugs 10170431, 12312133
- Release 11.2.0.3 requires patches for Oracle bugs 12312133, 16052165

**Patches required**

Enabling BCT on a physical standby database without these patches is **not recommended** because of serious performance and stability issues.

BCT on a primary database has been stable since Oracle version 10.2.0.5. In order to make use of BCT (>11.2.0.4), The Physical Standby Database must be in a "Managed Recovery Mode", i.e. achieved using "ALTER DATABASE RECOVER **MANAGED STANDBY DATABASE**".

## Physical standby database support matrix

Oracle Version	Apply Mode	Notes
11.x and 12.x in <b>Level Backup</b> mode; 12.x in <b>SCN Backup</b> mode	Archive Apply mode	No special restrictions.
	Real-Time Apply mode (RTA)	LogSync must be enabled for all database versions if RTA is enabled
11.x in <b>SCN Backup</b> mode	Archive Apply mode	If the Physical Physical Standby Database is at version 11.2.0.4 or above, no special actions are required.  Due to Oracle bug 10146187, <b>Redo Apply</b> must be stopped and the database opened in <b>read-only</b> mode during SnapSync. See the section <i>Stopping and Restarting Redo Apply</i> below for more information.

Oracle Version	Apply Mode	Notes
Real-Time Apply mode	If the Physical Standby Database is at version 11.2.0.4 or above, no special actions are required.	<p>LogSync must be enabled.</p> <p>Due to Oracle bug 10146187, <b>Redo Apply</b> must be stopped and the database opened in <b>read-only</b> mode during SnapSync. See the section <i>Stopping and Restarting Redo Apply</i> below for more information.</p> <p>In addition, to avoid Oracle Bug 13075226, which results in a hang during the restart of Redo Apply, Delphix requires disabling using BCT on the standby database. The hang occurs when BCT is enabled on a standby database that uses SCN backup mode.</p> <div style="border: 1px solid #f0e68c; padding: 10px; margin-top: 10px;"> <p><b>⚠ Patch required</b></p> <p>SnapSync will fail if running Oracle 11.2 before 11.2.0.4 when using SCN backups and real-time apply mode, Use level based backups instead.</p> <p>If the Oracle installation has already been patched for Oracle bug 13075226, or once the patch is applied, use the CLI to update the repository for this installation so that applied Patches include Oracle bug number 13075226. If the repository does not indicate that Oracle bug 13075226 for the repository has been addressed, SnapSync will not be possible when using SCN backups and real-time apply.</p> <p>See <i>Updating Repository for Oracle applied patches with the Command Line Interface</i> below for details on how to update the repository.</p> </div>
18.0.0.0 - 19.3.0.0	Real-Time Apply mode	Oracle patch 29056767 installed, Failure to install this patch may result in SnapSync failure with error.

#### Level backup mode for snapSync

By default, the Delphix Engine's SnapSync feature uses **SCN Backup** mode and is designed to not interfere with other backups that may already be in use. However, in cases where RMAN is not being used outside of the Delphix Engine, the Delphix Engine can use the **Level Backup** mode that improves SnapSync behavior on Oracle 11g physical standby databases. In this mode, **redo apply** does not have to be stopped during SnapSync. See [Advanced Data Management Settings for Oracle dSources](#) for more information about SnapSync settings.

#### Requirements for using level backup mode

Customer not backing up their physical standby with RMAN:

- Set CONTROL\_FILE\_RECORD\_KEEP\_TIME to 365

OR all of the following:

- Physical standby database running Oracle 11.2.0.2 or later version
- All RMAN backups must use tags
- RMAN CROSSCHECK commands must specify tags
- RMAN DELETE commands must specify tags

- RMAN DUPLICATE commands must specify tags
- Set CONTROL\_FILE\_RECORD\_KEEP\_TIME to 365

 Failure to meet all of these requirements will cause external RMAN backups to be incomplete or result in corrupt SnapSync snapshots. Switching from SCN to LEVEL mode will force a new LEVEL 0 backup.

### Stopping and restarting redo apply

Oracle bug 10146187 requires stopping of redo apply before an SCN-based incremental backup can be issued. These scripts can be used as pre- and post-scripts during the dSource linking process to stop and restart **Redo Apply**.

- SnapSync pre-script: [disableStandby.sh.template](#)
- SnapSync post-script: [enableStandby.sh.template](#)

These scripts must be modified for local use, particularly in regard to whether the physical standby database operates in MOUNTED or OPEN mode.

 Failure to properly customize these scripts could violate your Oracle license terms by running redo apply on an open database, which requires an Oracle Active Data Guard license.

### Linking and provisioning a mounted standby

 **Warning:**

When you link a standby database in the mounted mode and have not been opened read-only, the data files for temporary tablespaces will be present in v\$tempfile but will not actually be created yet, and therefore will indicate 0 file size. As a result, any VDB provisioned from a snapshot taken in this state will end up with the same tablespaces and datafiles created, but with a default file size of 52428800 bytes.

For databases that are in the **mounted** state, the Delphix database user account must be **SYS** (having the **SYSDBA** role), **SYSBACKUP** (having the **SYSBACKUP** role) or **SYSDG** (having the **SYSDG** role).

 **SYSBACKUP** and **SYSDG** roles are only available in Oracle 12.1 and later releases.

However, for an **open** standby (Active Data Guard) database, only a regular database user account is required.

Connecting to a **mounted** standby with a **SYS** user account requires that the mounted standby be configured with a password file. Delphix does not capture the password file during SnapSync, and for this reason, cannot provision or sync validate a database with a SYS user. A secondary, regular database user account can be specified through either the **Delphix Management** application or CLI. This database user will then be used to connect to the database during provisioning and validated sync. Note that the **SYS** user is still required to perform snapshots of the source database.

In the **Delphix Management** application, the **non-SYS user** can be specified from within the **Add dSource** wizard, or on the back of the Oracle dSource after linking.

### Configuring a standby PDB in mount mode

 This procedure is optional and only applies if SCM is disabled.

To configure a standby PDB in the mount mode, you must also provide a non-SYS user for both the CDB and the PDB. The PDB non-SYS user can only be added via the CLI. You must perform a fresh SnapSync after adding the non-SYS user.

#### Pre-requisite

In order for Delphix Engine to connect, you must configure a static listener configuration for the PDB. You can configure a static listener by adding a configuration into listener.ora and restarting the listener.

```
SID_LIST_LISTENER=
(SID_DESC=
(GLOBAL_DBNAME=CDOML0SR4F71PDB1)
(SID_NAME=stby18c)
(ORACLE_HOME=/u01/app/oracle/product/18.0.0.0/dbhome_1)
)
)
```

In the above example configuration, GLOBAL\_DBNAME is the PDB name and SID\_NAME is the SID of the CDB.

#### Procedure

Run the following commands to configure a PDB and CDB in the mount mode.

1. Update PDB non-SYS user.

```
# Update PDB nonsys user
delphix> /sourceconfig
delphix sourceconfig> select RH74PDB04
delphix sourceconfig 'RH74PDB04'> update
delphix sourceconfig 'RH74PDB04' update *> set nonSysUser=delphix
delphix sourceconfig 'RH74PDB04' update *> set
nonSysCredentials.type=PasswordCredential
delphix sourceconfig 'RH74PDB04' update *> set
nonSysCredentials.password=delphix
delphix sourceconfig 'RH74PDB04' update *> commit;
```

2. Update CDB non-SYS user.

```
# Update CDB nonsys user
delphix> /sourceconfig
delphix sourceconfig> select rh74cdb2
delphix sourceconfig 'rh74cdb2'> update
delphix sourceconfig 'rh74cdb2' update *> set nonSysUser=delphix
delphix sourceconfig 'rh74cdb2' update *> set
nonSysCredentials.type=PasswordCredential
delphix sourceconfig 'rh74cdb2' update *> set
nonSysCredentials.password=delphix
delphix sourceconfig 'rh74cdb2' update *> commit;
delphix sourceconfig 'rh74cdb2'>
```

3. Perform sync of the PDB.

```
# Perform sync of PDB
delphix> /database
delphix database> select RH74PDB04
delphix database 'RH74PDB04'> sync
```

### Setting the Non-Sys User on the Oracle dSource

1. Create the delphix\_db user in the primary database.
2. Log into the Delphix Management application.
3. From the **Manage** menu, select **Datasets**.
4. From the Configuration tab select the Oracle dSource for which you want to add a **non-SYS** user.
5. Click the dSource's icon to open the dSource information pane.
6. Click the Edit button next to **Non-SYS User**.
7. Enter a non-SYS user and credentials that exist on the standby.
8. Click the **Accept** button to save this user and associated credentials.

The non-SYS user will be used to connect to all VDBs provisioned from snapshots of this dSource that are created after the non-Sys user has been set.

### Updating repository for applied patches with the command line interface

1. Select the repository of the database

```
delphix> repository select '/opt/app/oracle/product/11.2.0.2/db_1'
```

2. Execute the `update` command.

```
delphix repository '/opt/app/oracle/product/11.2.0.2/db_1'> update
```

3. Set `appliedPatches` to list current patches applied to the repository.

```
delphix repository '/opt/app/oracle/product/11.2.0.2/db_1'update *> set
appliedPatches=13075226
```

4. `Commit` the operation.

```
delphix repository '/opt/app/oracle/product/11.2.0.2/db_1'update *> commit
```

### Setting the Non-Sys User with the Command Line Interface

1. Select the `source config` of the mounted standby.

```
delphix> sourceconfig select pomme
```

2. Execute the `update` command.

```
delphix sourceconfig "pomme"> update
```

3. Set the `nonSysUser` and `nonSysCredentials` to a non-SYS user that exists on standby.

```
delphix sourceconfig "pomme" update *> set nonSysUser=<non-sys-username>  
delphix sourceconfig "pomme" update *> set  
nonSysCredentials.type>PasswordCredential  
delphix sourceconfig "pomme" update *> set nonSysCredentials.password=<non-sys-  
password>
```

4. Commit the operation.

```
delphix sourceconfig "pomme" update *> commit
```

## Specifying external data directories for Oracle dSources and VDBs

This topic describes the process for including external data files with dSource snapshots and VDBs.

In the following places, you can specify the directory for any external data files that should be included with dSource snapshots:

- During the dSource linking process click on the **Advanced** section of the **Data Management** screen
- After you have created the dSource go to the **Configuration** tab

## External file import for the Delphix engine and VDBs

The Delphix Engine will not fetch external tables or external data types such as BFILE. Instead, in order to link external data files to the source database and make it available to the Delphix Engine, you must create a directory in the file system and the database. Any data files in the directory you specify will be applied, recursively, to the dSource.

External data will be provisioned to each VDB that is created from this dSource. You will need to update the external file/data type definition to point to the new location after creating VDBs. Provisioning a VDB with external data creates a directory named **external** in the VDB mount point location.

## Configuring the rsync command location for an environment

Files from the external data directory are fetched using the rsync command installed in the source environment. In order to SnapSync a dSource with an external data directory, rsync must be installed in the source environment. If rsync is installed in a non-standard location, the path to the rsync command can be configured in the **Environment Details** for the source environment on the **Environment Management** screen.

## Example of attaching and redirecting external data files for Oracle databases

This example uses two environments:

1. **172.16.200.446** as the source environment **dinosaur** as the source database
2. **172.16.200.447** as the target environment **vdino** as the target database

## Linking a dSource

1. Create an external data directory and an external data file, and attach the directory to the source database.
  - a. Log into **172.16.200.446** as the environment user.
  - b. Create a physical directory on the source environment. `$ mkdir /work/extdata`
  - c. Create a directory in Oracle.

```
$ sqlplus / as sysdba
SQL> create or replace directory extdata as '/work/extdata';
```

- d. Create a text file `/work/extdata/exttab.dat`.

```
$ cat > /work/extdata/exttab.dat
1, aaa
2, bbb
3, ccc
^C
```

- e. Create an external table `exttab`.

```
$ sqlplus / as sysdba
SQL> create table exttab (id number, text varchar2(10))
      2 organization external (default directory extdata location('exttab
.dat'));
```

- f. Query the table.

```
SQL> select * from exttab;
      ID TEXT
-----
      1 aaa
      2 bbb
      3 ccc
```

2. During the process of linking the dSource to the **Dinosaur** database, or in the dSource's **Configuration** tab after creating the link, enter `/work/extdata` in the **External Data Directory** field.

#### Provisioning a VDB

1. Provision **vdino** from **Dinosaur**.
2. Modify the directory **extdata** in **vdino**
  - a. Log into the target environment **172.16.200.447**
  - b. Set **SID** to **vdino**

```
$ export ORACLE_SID=vdino
```

- c. A query to `exttab` will fail.

```
$ sqlplus / as sysdba
SQL> select * from exttab
select * from exttab
*
ERROR at line 1:
ORA-29913: error in executing ODCIEXTTABLEOPEN callout
ORA-29400: data cartridge error
KUP-04063: unable to open log file EXTTAB_23394.log
OS error No such file or directory
ORA-06512: at "SYS.ORACLE_LOADER", line 19
```

3. Modify directory to the new location.

```
SQL> create or replace directory extdata as '/mnt/provision/vdino/external';
```

4. Query `exttab` again.

```
SQL> select * from exttab;
      ID TEXT
```

```
-----  
1  aaa  
2  bbb  
3  ccc
```

## Linking to Oracle dSources with RMAN compression or encryption enabled

This topic describes the behavior of the Delphix Engine when linking to a dSource with RMAN compression or encryption enabled.

In earlier versions of the Delphix Engine, the dSource linking process would fail if RMAN compression or encryption was enabled. In order for the linking process to complete, the administrator was required to ensure that compression was not enabled for device type **SBT\_TAPE**, and that encryption was also not enabled.

With the Delphix Engine, linking a dSource succeeds if compression or encryption is enabled, but the RMAN backup that creates the dSource will not be compressed or encrypted. This is true in the case where the administrator has enabled compression for tape, and in the case where the administrator is using OSB and has enabled encryption for tape.

You can check the RMAN compression and encryption settings with the commands `show device type` and `show encryption for database`, respectively.

If compression is enabled on a source environment, then it may need to be enabled for the target environment. Compression should be enabled for target environments if all segments in a source environment utilize **NOCOMPRESS** or **COMPRESS="BASIC"**.

## Upgrading dSources after an Oracle upgrade

This topic describes how to upgrade dSources after an Oracle database upgrade.

### Prerequisites

Do not suspend LogSync on the Delphix Engine during an Oracle upgrade of the source environment. LogSync will detect the Oracle version change. It will then notify you to refresh the host and use the Update icon on the configuration tab for all the associated dSources and VDBs (see below). Follow all Oracle instructions and documentation.

**⚠** In order to upgrade your Oracle dSource from Non-Multi-Tenant (Non-MT) to Multi-Tenant(MT) database, please refer to [Prepare and Upgrade a Non-MT Oracle dSource to MT](#) section.

There are 2 ways to apply a PSU (Patch Set Update)/Oracle upgrade:

- Apply to existing ORACLE\_HOME. Best if on Delphix v4.1.x or higher.
- Create a new ORACLE\_HOME (or clone an existing one) and then apply the PSU to the new ORACLE\_HOME

### Applying to an existing ORACLE\_HOME

1. Following Oracle documentation, patch the ORACLE\_HOME and the database.
2. Click the refresh icon on the top right of the selected environment.

3. On the Refresh Environment pop-up window, click **Refresh**.
4. Under the **configuration** tab, go to the PDB and verify that the **Repository** and/or **Version** has been updated.

### Creating a new ORACLE\_HOME

1. Refresh the environment from the Delphix Management application.
2. In the **Databases** tab, verify that the new ORACLE\_HOME appears as an ORACLE Installation.
3. Following Oracle documentation, patch the production database, etc.
4. Click **Manage**.
5. Select **Datasets**.
6. Expand the group(s) containing all the non-multitenant and multitenant dSources.
7. Select **dSource**. For upgrading a PDB or multitenant dSource, select the container CDB **dSource**.
8. Click the **Configuration** tab.
9. From the **Actions** menu (...), select **Upgrade** to switch the ORACLE\_INSTALLATION to the new one.
10. Under the **configuration** tab, go to the PDB and verify that the **Repository** and/or **Version** has been updated.

#### **i** Updating the Oracle user after an upgrade

There may be cases when you upgrade the Oracle home and the Oracle User (the OS user who owns the Oracle binary) is a different user than the previous Oracle User. You will then need to update the Oracle User for each environment, and then re-connect each dSource and VDB to the upgraded Oracle home using the new Oracle User.

The new Oracle User must be in the same OS group (for example, dba or oinstall) as the previous one.

1. Log into the Delphix Management application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **environment** where you want to add the user.
5. Next to **Environment Users**, click the **Pencil** icon to edit the new user.
6. Follow the procedure to upgrade the dSources and VDBs described in this topic.

#### Post-requisites

After upgrading the dSource to a new major release of Oracle (11.2.0.4 to 12.1 for example), you must re-run the [createDelphixDBUser.sh](#) script.

## Oracle source continuity

### Overview

In earlier versions of the Delphix Engine, when an Oracle database underwent a resetlogs operation, you were required to re-link the Oracle source. This meant that you had to completely back up the Oracle database and store it again on the Delphix Engine. If any virtual databases (VDBs) were provisioned from the dSource and needed to be saved, you had to rename and save the old dSource, resulting in a possible doubling of storage space consumed on the Delphix Engine. The old VDBs could not be refreshed to the relinked dSource.

Beginning with Delphix Engine version 4.1.1.0/4.0.6.0, the Oracle database no longer requires you to re-link sources after a resetlogs operation. The Delphix Engine will detect this condition, automatically take a new full backup, and create a new TimeFlow for the next SnapSync of the source. Benefits of the Oracle Source Continuity feature include:

- Lower storage costs and easier administration.
  - Only the changed blocks of the new SnapSync backup will be stored on the Delphix Engine. Because of the way the Delphix Engine handles duplicate blocks, the full backup likely has a storage requirement similar to an incremental backup.
- Existing VDBs provisioned from previous snapshots for the source will remain.
  - You can use and refresh those VDBs to the new snapshot

The improved user workflow replaces the old user workflow, which directed users to troubleshoot when SnapSync would fail. Begin Oracle Source Continuity in the following way:

1. The database undergoes a resetlogs operation.
2. If LogSync is enabled, it generates a fault and stops.
3. Start SnapSync. The SnapSync does a full restore of the database to a new TimeFlow, clears the fault, and restarts LogSync. If you created VDBs prior to the resetlogs operation, they will still exist after the SnapSync; you can refresh them from the new snapshot.

### Creating a new timeFlow

When LogSync detects the resetlogs operation, it will still stop and generate a fault. LogSync must stop because a new timeline has been created on the database. This usually happens because the database has been rewound to a past point. The transaction logs being generated on the new timeline are out of sync and conflict with logs from the old timeline. The data files are also out of sync with the data files on the Delphix Engine. You must create a corresponding new Timeflow on the Delphix Engine to store the new logs and new versions of the data files. This requires taking a new backup of the database.

Once LogSync detects the reset operation and throws the fault, no more changes will be retrieved from the database until you start a new SnapSync. This SnapSync will take a full backup, clear the fault, and restart LogSync. Only the new snapshot and Timeflow will be visible in the dSources view. Previous snapshots and Timeflow will still exist and be visible through the command-line (CLI) Capacity screen.

The following CLI output shows that the old and new Timeflow and snapshots are still available. The name of the original Timeflow for the database is "default." The name of the new Timeflow that was created during the SnapSync is "CLONE@2015-01-15T17:07:20."

```
delphix> /TimeFlow list display=name,container
```

NAME	CONTAINER
'CLONE@2015-01-15T17:07:20'	dbdhcp1
default	dbdhcp

```
delphix> /snapshot list display=name,container,TimeFlow
```

NAME	CONTAINER	TimeFlow
'@2015-01-16T00:50:08.784Z'	dbdhcp1	default
'@2015-01-16T00:52:13.685Z'	dbdhcp1	default
'@2015-01-16T00:53:46.873Z'	dbdhcp1	default
'@2015-01-16T00:55:18.079Z'	dbdhcp1	default
'@2015-01-16T01:08:02.411Z'	dbdhcp1	'CLONE@2015-01-15T17:07:20'

The old snapshots and Timeflow will still be subject to logfile and snapshot retention policies. You can also delete the snapshots manually. In addition, you can use the CLI to provision from the old TimeFlow.

## Oracle liveSources

### Oracle liveSources overview

Prior to Delphix Engine version 4.2, users ran reports against virtual databases (VDBs) that they created with the Delphix Engine. Although this workflow helped them offload the reporting load from production, the data in the VDBs was not updated asynchronously. If users wanted newer data, they had to stop their reporting applications, refresh their VDBs, and resume. In the current release, you can run reports against data that is constantly being updated. There is one live data feed for each source database that is linked as a dSource on the Delphix Engine. You can point your reporting applications to this live feed. Additionally, you will continue to have all existing Delphix functionality from the dSource, such as creating read/write VDBs.

### Understanding Oracle liveSources

Oracle LiveSources leverage native Oracle Active Data Guard technology to keep a standby database up-to-date with changes happening on the source. The standby database is kept open for reads while it applies changes from the source. You can now connect to this standby database for real-time reporting needs. Using Delphix in conjunction with Active Data Guard gives you the ability to get both live up-to-date data and historical points in time from which you can provision virtual databases.

### Understanding how to use Oracle liveSources

#### **Oracle liveSources provide a read-only live data stream from Delphix**

You can convert an Oracle dSource to a LiveSource, which is a real-time read-only feed of the linked source. You can access the LiveSource using a JDBC string. Internally, a LiveSource is a standby database instance tracking the Linked Source in real-time managed mode and opened in read-only mode.

#### **Understanding Oracle liveSources with data age and threshold**

One of the important utilities of a LiveSource is that it provides a real-time feed of the linked source. In some instances, due to slow networks or other reasons, the LiveSource might fall behind the linked source that it is tracking. When adding a LiveSource, you can specify a data age threshold. If the LiveSource falls behind the linked source by more than the data age threshold, the Delphix Engine will generate a fault and inform you.

The LiveSource information is displayed on the Status tab. Delphix continuously monitors the standby instance and notifies you of any abnormalities.

- Live Data Status - Indicates that the LiveSource standby database instance is actively receiving data from the source database
- Data Age - Displays the data age of the LiveSource

You can change the Data Age Threshold at any time by updating the threshold value located on the **Configuration > Data Management** tab.

### Oracle liveSources quickly sync with consistent snapshots

Taking snapshots of a LiveSource is instantaneous since the standby database for the LiveSource is constantly receiving data from the source database and recovering it. Taking snapshots occurs instantaneously by taking a filesystem level snapshot of the data on the Delphix Engine without requiring an RMAN backup of the source database. All LiveSource snapshots are consistent; as a result, provisioning from LiveSource snapshots is fast, because no database recovery needs to happen.

### Oracle liveSources use resync and apply

Resync is a way to refresh the LiveSource to the current point in the linked source. The following situations require a Resync to be performed:

- There are unresolvable gaps in the log sequence – for example, logs from the source database deleted before the primary database could ship them over to the LiveSource standby.
- The source database was taken through a point in time recovery/flashback, resulting in a changed incarnation.
- The source database contains non-logged changes. In this case, a Resync is needed only if you are interested in moving the non-logged data over to the LiveSource.
- The LiveSource is significantly behind the source database due to network communication issues or a large number of writes.

LiveSource Resync is a two-step operation of:

- **Start LiveSource Resync** – Start Resync performs an incremental backup of the source database to transfer the latest changes to the Delphix Engine. This operation does not affect the availability of the LiveSource
- **Apply LiveSource Resync** – Applying the Resync data will perform one more incremental backups from the source database to ensure up-to-date data, and recreate the LiveSource instance while preserving all the configurations. This operation requires downtime for the LiveSource.
- **Discard LiveSource Resync** – If the prepared resync data is no longer needed or resync has become obsolete (for example, another controlled change has been done on the source database), you can discard the current resync data with Discard LiveSource Resync. The next Resync will refetch data from the source database.

Pre-requisites: configuration and installation of staging environments to host a standby database

**Oracle active data guard required**

The LiveSource feature requires an Active Data Guard license. Delphix uses Active Data Guard to replicate changes from the source database that it creates on the staging environment.

**Network requirements**

LiveSource requires a Data Guard connection between the source and the standby database which utilizes TNS listeners associated with the databases.

**Database requirements**

LiveSource requires Enterprise Edition of Oracle Database.

LiveSource supports:	LiveSource does not support:
<b>Oracle support matrix</b>	
Oracle 11g and non-multi tenant Oracle 12c, 18c, and 19c	Oracle Standard Edition on the source and staging environments
Physical and standby source databases	LiveSources running on a RAC

## Oracle liveSource user workflows

Please use the following documentation as a guide to identify and act on common Oracle liveSource User Workflows. The following table of contents includes steps for how to convert a dSource into a liveSource, a provision from a liveSource, sync a liveSource, convert a liveSource back to a dSource, and many other data procedures.

### Converting to liveSource from a dSource

To get a live feed to the source database data through the Delphix Engine, you must first link the database to the Delphix Engine to create a dSource. You can then convert the dSource into a liveSource by following the steps outlined below:

1. In the left-hand panel, click the **dSource**.
2. From the Actions menu (...) select **Convert to liveSource**, as highlighted below. This launches the **Convert to liveSource** wizard.

### Convert to liveSource database wizard

1. In the Overview tab select **Next**.
2. Enter a **DB Unique Name** for the liveSource.
3. Enter a **Database SID** for the liveSource.
4. Click **Next**.

 The liveSource database name must be the same as the database name of the primary database; therefore, this value is read-only.

### Convert to liveSource, environment tab

Select the environment on which the liveSource will be created:

1. Select an **Environment User** for the liveSource instance.
2. Enter the **Mount Point** for the liveSource instance.
3. Select **Listeners** as needed. If you enable **Auto Select Listeners**, the Delphix Engine will pick the first available listener from the environment.
4. Click **Next**.

### Convert to liveSource, configuration template tab

1. Select **VDB configuration templates** for the liveSource.
2. Enter additional **DB configuration parameters** for the liveSource.
3. Click **Next**.

### Convert to liveSource, data management tab

1. Enter the **data age warning threshold** for the liveSource. If the data in liveSource lags behind the source database by more than this threshold, the Delphix Engine will raise a fault and notify you.
2. Click **Next**.

### Convert to liveSource, hooks tab

1. Enter the **operations** to be performed on initial conversion. These operations are performed after the Delphix Engine has created the standby database for the liveSource.
2. Click **Next**.

 These operations will also be performed when resyncing a liveSource.

Convert to liveSource, summary tab

1. Review the configuration summary.
2. Click **Convert** to begin the conversion.

Setting up log transport between a dSource or primary database and a liveSource or standby database

After adding a liveSource instance, you must configure the log transport between the dSource or primary database and the liveSource or standby database. For details on configuring a standby database, refer to the Oracle Data Guard Concepts and Administration guide.

At source/primary database

1. Configure the `LOG_ARCHIVE_CONFIG` parameter to enable the sending of redo logs to remote destinations and the receipt of remote redo logs (the liveSource instance). For example: `alter system set log_archive_config='DG_CONFIG=(sourcedb, liveSource)' scope=both;`
2. Configure the `LOG_ARCHIVE_DEST_n` parameter to point the redo logs to the liveSource instance. For example: `alter system set log_archive_dest_2='SERVICE="(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=liveSource.dcenter.delphix.com)(PORT=1521))(CONNECT_DATA=(SERVICE_NAME=liveSource)(SERVER=DEDICATED)))" ASYNC VALID_FOR=(ONLINE_LOGFILE, PRIMARY_ROLE) DB_UNIQUE_NAME=liveSource' scope=both;`
3. Create a **passwd file** for the liveSource into the target site.
4. Configure the corresponding `LOG_ARCHIVE_DEST_STATE_n` parameter to identify whether the log transport is enabled. For example: `alter system set log_archive_dest_state_2='ENABLE' scope=both;`
5. Configure the `STANDBY_FILE_MANAGEMENT` parameter to enable automatic standby file management. For example: `alter system set standby_file_management='AUTO' scope=both;`

RAC instance as standalone environment

For RAC instances that are discovered as Standalone type environments, please apply the following steps instead of the steps above.

1. `alter system set log_archive_config='DG_CONFIG=(sourcedb, liveSource)' sid='' scope=both;`
2. `alter system set log_archive_dest_2='SERVICE=liveSource ASYNC VALID_FOR=(ONLINE_LOGFILE, PRIMARY_ROLE) DB_UNIQUE_NAME=liveSource' sid='' scope=both;`
3. Set up **tnsnames.ora** in both source and target sites.
4. Make sure to have the same password file in all RAC instances and target site.
5. `alter system set log_archive_dest_state_2='ENABLE' sid='' scope=both;`

6. `alter system set standby_file_management='AUTO' sid='' scope=both;`

**i** The Delphix DB user must be updated to include grants for select on v\$managed\_standby and v\$dataguard\_stats in order to access MRP information and DataGuard statistics:

```
grant select on v_$managed_standby to <delphix DB username>;
create synonym <delphix DB username>.v$managed_standby for v_$managed_standby;
```

```
grant select on v_$dataguard_stats to <delphix DB username>;
create synonym <delphix DB username>.v$dataguard_stats for v_$dataguard_stats;
```

At the staging environment where the liveSource standby database environment is running

1. Configure the `FAL_SERVER` parameter to point to the primary database for proper fetch archive log function. For example:

```
ALTER system SET fal_server='service="(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)
(HOST=sourcedb.dcenter.delphix.com) (PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=sourcedb) (SERVER=DEDICATED)))"' ;
```

2. If not already created, configure a password for Data Guard.

Removing a liveSource

1. In the **Datasets** panel, click the **liveSource**.
2. Click the **Configuration** tab.
3. From the Actions menu (...) select **Convert to dSource**.
4. Click **Convert to dSource**.

Taking a snapshot on a liveSource

To take a snapshot of a liveSource:

1. In the **Datasets** panel, select the **liveSource**.
2. In the upper right-hand corner, click the **camera** icon.  
liveSource snapshots are instantaneous, Quick Provision snapshots. They do not require an RMAN backup of the source database

Provisioning from a liveSource TimeFlow

Provisioning from a liveSource Timeflow is the same process as provisioning from a snapshot for dSource Timeflow. The only difference is that you will select a liveSource and a liveSource snapshot.

Enabling, disabling, and detaching a liveSource

A liveSource is **enabled** the same way as a regular dSource.

1. Login to the Delphix Management application as **admin** or another user with administrative privileges.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **liveSource** you want to enable.
5. From the Actions menu (...) select **Enable**.

6. Click **Enable** to confirm.

**i** When you enable the liveSource, the Delphix Engine will recreate the standby database on the staging environment.

A liveSource is **disabled** the same way as a regular dSource. Disabling a liveSource will stop further operations on the Delphix Engine related to the liveSource.

1. Login to the Delphix Management application as **admin** or another user with administrative privileges.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **liveSource** you want to disable.
5. In the upper right-hand corner, from the **Actions** menu (...) select **Disable**.
6. In the Disable dialog select **Disable**.

When you are ready to enable the liveSource again, from the Actions menu (...) select **Enable**, and the liveSource will continue to function as it did previously.

**i** Disabling a liveSource shuts down the standby database that Delphix manages on the staging environment.

You can detach a liveSource in the same way as [detaching a regular dSource](#). Detaching a liveSource will implicitly convert the liveSource into a regular dSource. After a dSource is re-attached, you can convert it back to a liveSource.

### Resyncing a liveSource and applying the resync

Resync is a way to refresh the liveSource to the current point in the linked source. Resync is a multi-phase operation comprised of the following:

#### Perform resync

1. Click **Manage**.
2. Select **Datasets**.
3. Select your liveSource.
4. From the Actions menu (...) select **Start liveSource Resync**. The liveSource can stay up while the Resync is in progress.

#### Discarding resync data

##### Prerequisites

- Resync is started and ready to apply

After Resync has finished, you can choose to not apply but rather discard the data that was brought over from the source database as part of Resync.

##### Procedure

To discard the data:

1. Click **Manage**.
2. Select **Datasets**.
3. Select your liveSource.
4. From the Actions menu (...) select **Discard liveSource Resync**.

## Applying resync data

### Prerequisites

- Resync started and ready to apply

### Procedure

1. Click **Manage**.
2. Select **Datasets**.
3. Select your liveSource..
4. From the Actions menu (...) select **Apply liveSource Resync**.
5. If the apply resync data process fails, first investigate and resolve the cause of failure, such as a full disk. Then follow the procedure to start resync.

## Migrating a liveSource

1. Click **Manage**.
2. Select **Datasets**.
3. Select your liveSource.
4. From the Actions menu (...) select **Disable**.
5. From the Actions menu (...) select **Migrate**.
6. Update the environment, user, and repository. From the **Configuration** tab select the **Source** sub-tab and click the Pencil (edit) icon next to the Database.
7. Enable the **dSource**.

After the liveSource is migrated to a different staging environment, you must ensure that the log transport between the source database and the liveSource instance on the new staging environment is set up correctly.

## Oracle RAC dSource node addition or deletion

### Managing Oracle RAC node changes in Delphix

The addition and removal of cluster nodes from an Oracle Cluster must be considered where Delphix has dSources attached to RAC databases running from the same cluster environment or RAC VDB's provisioned out to those cluster nodes. Each scenario needs to be considered in its own right as dSources and VDBs require specific changes be made to accommodate the removal of a cluster node.

The changes required by Delphix and made within Oracle that need to be considered when the Oracle cluster node configuration alters and the process for removing or adding an Oracle cluster node is best demonstrated through an example.

The oracle cluster is comprised of 2 cluster nodes as seen from olsnodes.

```
[oracle@oelc9n1 ~]$ su - grid
Password:
Last login: Thu Nov 30 17:15:36 AEDT 2017 on pts/1

[grid@oelc9n1 ~]$ . oraenv
ORACLE_SID = [grid] ? +ASM1
The Oracle base has been set to /u01/app/grid

[grid@oelc9n1 ~]$ olsnodes -s -t
oelc9n1 Active Unpinned
oelc9n2 Active Unpinned
```

Node 2 in the cluster oelc9n2 is the node targeted for removal from the Oracle cluster.

### Delphix dSources and removing Oracle cluster nodes

In this example, Delphix has a 2 Node Oracle RAC database being ingested as a dSource. The sample database name is db121 comprised of 2 RAC instances db1211 and db1212. The instance impacted by the removal of node oelc1n2 is db1212. The dSource configuration appears as follows:

The screenshot displays the Oracle Cloud console configuration for a database instance named 'db121'. The interface is divided into a left-hand navigation pane and a main configuration area. The navigation pane shows 'Datasets' with a filter set to 'none', and a list of 'dSources' and 'VDBs'. The 'dSources' section is expanded, showing 'db121' as an active source. The main configuration area is titled 'db121' and has tabs for 'Timeflow', 'Status', and 'Configuration'. The 'Configuration' tab is active, with sub-tabs for 'Source', 'Policies', 'Data Management', 'Masking', and 'Hooks'. The 'Source' sub-tab is selected, showing the following details:

**Database**

- Unique Name: db121
- Name: db121
- Version: Oracle 12.2.0.1.0
- Size: 1.36GB
- User: delphix

**Environment**

- Name: oelc9n
- OS: Linux (CentOS)
- Timezone: America/New\_York,EST-0500
- User: oracle
- Repository: /u01/app/oracle/product/12.2.0.1/dbhome\_1

**Cluster Instances**

Node Name	Instance N...	Instance N...
oelc9n1	1	db1211
oelc9n2	2	db1212

The cluster node, its associated listeners and instances must be deleted from the cluster through Oracles RAC RDBMS and Clusterware software using the processes described in the Oracle documentation.

This begins with the removal of the RAC instance using the process detailed in the Oracle RAC documentation. This example is operating against an Oracle 12.1 RAC and Cluster and the documentation link this specific release is the following:

*Removing RAC instances and homes*

<https://docs.oracle.com/database/121/RACAD/GUID-CE995C7B-B420-4A4E-B4EA-E7A972277588.htm#RACAD7903>

Removal of the RAC instance is typically executed through the database configuration assistant dbca and using the UI provided through dbca the instance db1212 is removed from node oelc9n2. After the instance has been deleted using dbca, Oracles srvctl utility will show one instance only (db1211) running from node oelc9n1.

```
[oracle@oelc9n1 ~]$ srvctl config database -d db121

Database unique name: db121
Database name: db121
Oracle home: /u01/app/oracle/12.1
Oracle user: oracle
Spfile: +DATA/DB121/PARAMETERFILE/spfile.289.961441955
Password file: +DATA/DB121/PASSWORD/pwddb121.277.961441737
Domain:
Start options: open
Stop options: immediate
Database role: PRIMARY
Management policy: AUTOMATIC
Server pools:
Disk Groups: FRA,DATA
Mount point paths:
```

```

Services:
Type: RAC
Start concurrency:
Stop concurrency:
OSDBA group: dba
OSOPER group:
Database instances: db1211
Configured nodes: oelc9n1
Database is administrator managed
    
```

Following the removal of the instance, the inventory on the node to be removed is updated to reflect the removal of the Oracle Home that was running this dSource instance on the node. This too must be performed according to the Oracle documentation. Oracles utility runInstaller is used for Oracle inventory maintenance. This must be performed using the operating system owner of the RDBMS Home (in this case oracle)

With the RAC instance and RAC Home removed the node itself can be removed using the process detailed in Oracles Clusterware Administration documentation,

*Removing Oracle cluster nodes*

<https://docs.oracle.com/database/121/CWADD/GUID-8ADA9667-EC27-4EF9-9F34-C8F65A757F2A.htm#CWADD90992>

This must be performed as the Oracle Clusterware home operating system owner (in this case grid).

Removal of the node from within Oracles RDBMS and Clusterware software does not alter the fact that Delphix still sees the Oracle Cluster and RAC configuration as it was the last time an environment refresh was performed against the cluster.

The Environment in Delphix shows both cluster nodes are still present along with any node listeners that may have been discovered running on that node.

The dSource shows the node and both instances still present this needs to be cleaned up from a Delphix perspective.

### Aligning Delphix with the new Oracle cluster configuration

In order for Delphix to pick up on the latest changes to the environment (OELC9) in this case, the removal of an entire node from the Oracle Cluster an environment refresh must be performed.

This is performed through the environments management panel in the Delphix Management application and the refresh icon present on the top right-hand side of the panel (highlighted in red).

Clicking on the icon presents a prompt indicating that an environment refresh is about to be initiated.

Click on refresh to kick off the environment refresh action.

The environment refresh will force Delphix to re-examine the Oracle Cluster.

This will result in the environment and the dSource being updated based on the cluster's current node, instance and listener configuration where only one node oelc9n1 is present.

After the node removal, the cluster environment in Delphix will look as follows and only oelc9n1 appears in the cluster node list.

The dSource will now be comprised of only one instance db1211 running from node oelc9n1.

### Adding Oracle cluster nodes

You can add a node through the **Environments** management panel in the Delphix Management application and the **Refresh** icon present on the top right-hand side of the panel. Clicking on the icon presents a prompt indicating that an environment refresh is about to be initiated.

Click on the **Refresh** option to kick off the environment refresh action. The environment refresh will force Delphix to re-examine the Oracle Cluster. This will result in the environment and the dSource being updated based on the cluster's current node, instance, and listener configuration.

Delphix configuration steps to assign a VDB to a new cluster instance

1. Login to the Delphix Management application.
2. In the Oracle RDBMS, add the required number of nodes using the process detailed in the Oracle RAC [documentation](#)
3. In the Delphix Management Engine, select the VDB you want to edit.
4. From the right-side pane select the **Configuration** tab.
5. Refresh the VDB to view new nodes.
6. In the upper right-hand corner, from the **Actions** menu (...) select **Disable**.

7. In the **Disable** dialog select **Disable**.
8. Click the **pencil** icon next to **Cluster Instances** to be able to add new nodes.

10. Complete editing and then confirm using the **tick** icon.
11. From the Action menu (...), select **Enable**.

### Using the double sync option for Oracle snapSync

It is possible to request during Linking that a `doubleSync` is performed if `linkNow` is set to true. *(This is available in the GUI for linking starting in 5.0, and for manual Snapshots in 5.3.4.0, see notes below a CLI example).*

When the `doubleSync` option is selected, two SnapSyncs in a row are run, the first one will not even bother to get the archived logs to make the first Snapshot consistent. This means that LogSync will not run during the first SnapSync, or if LogSync is not enabled, the archived logs after the backup of the data will not be retrieved. Once the first snapSync finishes a second snapSync is started, starting LogSync if enabled, or taking an archived log backup after the data files have been backed up.

The `doubleSync` option is also available for manually initiated SnapSync, just like `forceFullBackup` option. As a `forceFullBackup` is similar to an initial load, `doubleSync` makes a great companion to `forceFullBackup`, although it is not needed to use both at the same time.

### Using the double snapSync option via the GUI

1. Login to the **Delphix Management** application.
2. Navigate to the Environment with a Data Source you want to link. Or, from the Datasets page, click the plus icon and select **Add dSource**.
3. In the Add dSource wizard, select the source database with the correct environment user-specified.
4. Enter your login credentials for the source database and click **Verify Credentials**. If you are linking a mounted standby, see the topics under [Linking Oracle Physical Standby Databases](#) for more information about how the Delphix Engine uses non-SYS login credentials. Click **Next**.
5. Enter a name for your dSource.
6. Select a **Database Group** for the dSource. Adding a dSource to a database group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. In the **Data Management** page select **Show Advanced** and then select **Enable Double SnapSync**. For more information, visit [Data Management Settings for Oracle Data Sources](#)

## Add dSource

- Preparation

Enable

8. Assign existing policies to the new dSource. New policies can be created and associated later.
9. Enter any scripts that should be run using the Hooks page.
10. Review the dSource Configuration and Data Management information, and then click Submit.

## Linking with doubleSync via the CLI

```
ssh delphix_admin@your engine
delphix > database
delphix database > link
delphix database link*> edit source.operations
delphix database link*> edit postSync
delphix database link*> add
delphix database link*> set command=""
delphix database link*> back; back
delphix database link*> edit preSync
delphix database link*> add
delphix database link*> set command=""
delphix database link*> back; back; back
delphix database link*> set source.config=XXXX
```

```
delphix database link*> set container.name=XXXX
delphix database link*> set container.group=XXXX
delphix database link*> set container.sourcingPolicy.logsyncEnabled=true
delphix database link*> set container.sourcingPolicy.logsyncMode=ARCHIVE_REDO_MODE
delphix database link*> set linkNow=true
delphix database link*> set doubleSync=true
delphix database link*> set dbUser=XXXX
delphix database link*> set environmentUser=XXXX
delphix database link*> set dbCredentials.password=XXXX
delphix database link*>commit
```

### Syncing with doubleSync via the GUI

1. Login to the **Delphix Management** application.
2. Navigate to the Datasets page, select the Dataset you want to SnapSync.
3. Click on the arrow next to the camera button.
4. Select **Snapshot with Params.**
5. Select **Double Sync** (and if so desired **Force Full Backup**) from the available parameters.

The screenshot shows a 'Snapshot' dialog box with the following options:

- Force Full Backup
- Double Sync
- Do Not Resume

At the bottom right, there are two buttons: 'Cancel' and 'Perform Snapshot'.

6. Select **Perform Snapshot.**

### Syncing with doubleSync via CLI

```
ssh delphix_admin@yourengine
delphix > database
delphix database > select XXXX
delphix database "XXXX"> sync
delphix database "XXXX"sync *> set doubleSync=true
delphix database "XXXX"sync *>commit
```

#### Additional information

- When two Double Sync snapshots are created, then the older snapshot will not be provisionable. Therefore, you should not attempt time flow repair operation as the logs required to make it provisionable, were not retrieved by design. Use the new snapshot for provisioning or refreshing operation.

DoubleSync is not available for multitenant databases.

## Linking dSources from an encrypted Oracle database

This topic describes the behavior of the Delphix Engine when linking to a dSource based on an encrypted Oracle database.

 This topic does not apply to vPDBs.

Beginning with version 10gR2, Oracle supports the encryption of permanent tablespaces using Transparent Data Encryption (TDE). You can link dSources from databases using TDE by following the basic procedure described in [Linking an Oracle Data Source](#). However, in order to provision a VDB from a dSource that is linked to an encrypted database, you must copy wallet files from the physical database in the source environment to the target environment. See [Provisioning a VDB from an Encrypted Oracle Database](#) for more information.

## Detaching and re-attaching Oracle dSources

### Overview

Each dSource contains metadata that associates it with the source database, as well as the data it has ingested from the source database in the form of snapshots up to that point. It is possible to detach, or unlink, a dSource from its source database. This breaks the association with the source database without affecting the data within the Delphix Engine. Detached dSources and their source databases have these properties:

- A detached dSources can still be used to provision a virtual database (VDB).
- You can re-link the source database as a different dSource.

### Prerequisites

Before detaching an Oracle dSource, you must capture the following RMAN configuration:

- Level or SCN based backups
- Data load channel settings: number of channels and files per channel

A dSource can only be attached to a new data source once it has been unlinked. The above RMAN configuration will be removed once the dSource is unlinked.

When attaching an Oracle dSource to a new data source, the new data source must be the same logical database satisfying the following constraints:

- Same dbid
- Same dbname
- Same creation time
- Same resetlogs SCN
- Same resetlogs time
- Same redo stream, where a log must exist with
  - Same sequence
  - Same thread
  - Same end SCN

For Oracle dSources, this procedure can be used to initially link from a standby server that is faster or less disruptive, unlink the dSource, and then attach it to the production server for subsequent incremental SnapSync operations. When you perform the attach operation, you will need the source config name of an unlinked database.

 It is possible to link a Single Instance Oracle database, unlink from it, and link to a RAC cluster and vice versa as long as the instances are for the same database. For example, initially link a Single Instance standby database of a RAC primary database, unlink the dSource, and then link the RAC primary database itself or another RAC standby database to the same dSource.

### Detaching a dSource

1. Login to the **Delphix Management** application as a user with **OWNER** privileges on the dSource, group, or domain.
2. Click **Manage**.
3. Select **Databases**.
4. Select the **database** you want to unlink or delete.
5. From the **Actions** menu (...) select **Unlink**. A warning message will appear.
6. Click **Unlink** to confirm.

To detach a dSource via CLI, see [Detaching and Attaching an Oracle dSource via CLI](#)

**i Rebuilding source databases and using VDBs**

In situations where you want to rebuild a source database but retain the existing dSource, you will need to detach the original dSource and create a new one from the rebuilt data source.

1. Detach the dSource as described in the procedure on this page.
2. You cannot attach a dSource with the same name as a dSource that is already attached. If you intend to give the new dSource the same name as the original one, rename the detached dSource.
  - a. At the top of the **Configuration** tab, next to the dSource's name, click the **Edit** (pencil) icon.
  - b. After renaming the dSource, click the green **checkmark**.
3. Create the new dSource from the rebuilt database.

You will now be able to provision VDBs from both the detached dSource and the newly created one, but the detached dSource will only represent the state of the source database prior to being detached.

**Attaching a previously detached dSource**

You can only re-attach databases that represent the same physical database.

**Via GUI**

To attach a dSource back into the Delphix Engine via GUI, from the **Delphix Management** application:

1. Select **Manage > Datasets**.
2. Select your dSource.
3. From the **Actions** menu (...) select **Link dSource**.
4. In the Link dSource dialog, fill in the information corresponding to the new dSource as well as its new environment.

## Link dSource

### Source Environment

RHEL 8.3 Oracle Source

5. Click **Link**.

Via CLI

To attach a dSource back into the Delphix Engine via CLI:

1. Login to the **Delphix CLI** as `delphix_admin` or a user with **OWNER** privileges on the dSource, group, or domain.
2. Select the dSource by name using `database select` .
3. Run the `attachSource` command.
4. Set the source config you want to attach to, using `set attachData.config=` . Source configs are named by their database unique name.
5. Set any other source configuration operations as you would for a normal link operation.
6. Run the `commit` command.

 **Backup mode for attaching Oracle dSources**

For Oracle dSources, the SnapSync backup option should be set to **SCN Backup** mode. **Level Backup** mode is based on information stored in the database control file. If the control file of the newly attached database does not contain information about the previous backups, an initial backup will be created. In addition, Block Change Tracking will not be in sync, and the next SnapSync will need to read the entire database to determine which blocks have changed. See [Advanced Data Management Settings for Oracle dSources](#) for more information about Backup Mode.

## Provisioning from a replicated Oracle dSource

This topic describes how to provision from a replicated dSource or virtual database (VDB).

The process for provisioning from replicated objects is the same as the typical VDB provisioning process, except that first you need to select the replica namespace containing the replicated object.

### Prerequisites

- You must have a dSource or VDB that has been replicated from one Delphix Engine to another, as described in [Replication Overview](#)
- The Delphix Engine containing the replicated dSource or VDB must have a compatible target environment that it can use to provision a VDB from the replicated dSource or VDB.

### Procedure

1. On the Delphix Engine containing the replicated dSource or VDB, login to the **Delphix Management** application.
2. In the top menu bar, click **Manage**.
3. Select **Datasets**.
4. From the list of replica namespaces, select the **replica namespace** that contains the dSource or VDB from which you want to provision.
5. The provisioning process is now identical to the process for provisioning standard objects.

### Post-requisites

Once the provisioning job has started, the user interface will automatically display the new VDB in the live system.

Detaching and re-attaching a PDB dSource from a data guard site

If you want to move the PDB dSource from one Data Guard site to another, then you must detach the PDB from the current environment and attach it to the new environment.

Perform the following procedure to attach or detach a PDB dSource from a Data Guard site.

1. Detach PDB from CDB (a).
  - a. Log into the **Delphix Management** application.
  - b. Select **Manage > Datasets**.
  - c. Select dSource.
  - d. From the **Actions** menu (...), select **Unlink dSource**.
  - e. Click **Unlink** to confirm.
2. If you are going to attach the PDB dSource from a different Data Guard site (Primary or Standby site), perform a fresh refresh of the existing environment to discover that host environment into Delphix. From the **Delphix Management** application:
  - a. Go to **Manage > Environments**.
  - b. If it is already a discovered environment, then from the **Actions(...)** menu, select **Refresh All**. Otherwise, select **Add Environment** to add the environment manually. For more information on adding an environment, see [Adding an Oracle Single Instance or RAC Environment](#). The new database configuration will appear in the Delphix Engine. **Note:** Do not add the discovered PDB as a dSource.
  - c. Detach the existing PDB dSource.
    - i. Select the dSource.
    - ii. From the **Actions** menu (...), select **Unlink dSource**.
    - iii. Click **Unlink** to confirm.
  - d. Using the Delphix CLI, detach the current CDB datasets associated with the same PDB dSource.

```
dlpx6010 database> select cdb19c1
dlpx6010 database 'cdb19c1'> detachSource
dlpx6010 database 'cdb19c1' detachSource *> ls
Properties
  type: DetachSourceParameters
  source: (required)
dlpx6010 database 'cdb19c1' detachSource *> set source=cdb19c1
dlpx6010 database 'cdb19c1' detachSource *> commit
Dispatched job JOB-16
DB_DETACH_SOURCE job started for "SugoPronto/cdb19c1".
DB_DETACH_SOURCE job for "SugoPronto/cdb19c1" completed successfully.
```

- e. Using the Delphix CLI, attach the new CDB configuration from the new environment/Physical Standby site.

```
dlpx6010 *> database
dlpx6010 database *> select cdb19c1
dlpx6010 database 'cdb19c1' *> attachSource
dlpx6010 database 'cdb19c1' attachSource *> set
attachData.type=OracleAttachData
dlpx6010 database 'cdb19c1' attachSource *> set
attachData.config=cdb19c1stb
dlpx6010 database 'cdb19c1' attachSource *> set
attachData.environmentUser=OEL7SITDE2/delphix
```

```
dlpx6010 database 'cdb19c1' attachSource *> commit;
cdb19c1
Dispatched job JOB-18
DB_ATTACH_SOURCE job started for "SugoPronto/cdb19c1".
Starting validation of attach parameters for database "cdb19c1".
Validation finished for database "cdb19c1".
Obtaining information from source database "SugoPronto/cdb19c1".
The dSource "cdb19c1stb" was successfully linked from source database
"SugoPronto/cdb19c1".
DB_ATTACH_SOURCE job for "SugoPronto/cdb19c1" completed successfully.
```

- f. Using the Delphix Engine user interface, attach the PDB.
  - i. Go to **Manage > Datasets**.
  - ii. Select the PDB from the datasets list.
  - iii. From the **Actions(...)** menu, select **Link dSource**. The Link dSource page appears.
  - iv. Perform the linking of the PDB from the new environment and click **Next**.

## Working with Oracle snapshots

This section lists the steps to take a snapshot and delete the same.

Taking a snapshot creates a new snapshot entry in the Oracle dSource's Timeflow. You can use either **snapshot (Default)** or **snapshot with Parameters** option for taking the snapshot.

### snapshot (Default)

Perform the following steps to take a snapshot:

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to snapshot.
4. Click the **Camera** icon. Alternatively, click the arrow next to the Camera icon and select **snapshot (default)**.
5. From the snapshot dialog box, select **Yes**.
6. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just created.
7. To delete the snapshot, select the snapshot you just created, and from the Actions menu (...), select **Delete snapshot**.
8. From the **Delete snapshot** dialog box, select **Delete**.
9. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just deleted.

### snapshot with parameters

Perform the following steps to take a snapshot:

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to snapshot.
4. Click the arrow next to the Camera icon and select the **snapshot with Params...** option.
5. From the snapshot dialog box, select one of the following:
  - a. **Force full backup** - If you select this option, then the Delphix Engine will perform an incremental backup by default. You must select this option only when a full backup is required. Full and Incremental backups consume the same space on the Delphix Engine.
  - b. **Double sync** - Selecting this option will perform a SnapSync operation as normal. After the first SnapSync is successful, the Engine will immediately perform a second SnapSync without waiting for the Log Files required for the first SnapSync to be made consistent. This is most useful when performing the initial SnapSync ( or when "Force Full Backup" is selected ) on a very large database that would lead to a large number of archive logs being required to make the SnapSync consistent. Provisioning from a SnapSync that requires excessive recovery is typically time-consuming.
  - c. **Do not resume** - If a failure is encountered during the initial SnapSync, the Delphix Engine can resume the SnapSync at a later date. This option will cause the engine to not resume, but rather to start the initial SnapSync over again.
6. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just created.
7. To delete the snapshot, select the snapshot you just created, and from the Actions menu (...), select **Delete snapshot**.
8. From the **Delete snapshot** dialog box, select **Delete**.
9. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just deleted.

## Moving the PDB to a new CDB

Perform the following procedure to move the dSource PDB to a new CDB.

1. Follow Oracle steps to unplug your dSource PDB and plug it into your chosen CDB (Refer to the Oracle webpage on [Plugging an Unplugged Pluggable Database](#)). After you have plugged your PDB dSource into the new CDB, discover the host environment that has the new CDB into Delphix, if it is not already discovered. Log into the **Delphix Management** application and do the following:
  - a. Select **Manage > Environments**.
  - b. Select your new CDB environment, then discover the new CDB where your PDB dSource is.
2. If you have already discovered the CDB, then:
  - a. Select **Manage > Environments**.
  - b. Select the dSource Environment where the PDB was plugged.
  - c. **Select the Refresh** icon.
3. When you are ready to attach the PDB dSource, log into the **Delphix Management** application, and do the following:
  - a. Select **Manage > Environments**.
  - b. Select your original PDB dSource Environment.
  - c. **Select the Refresh** icon.
4. To Attach the PDB dSource back into the Delphix Engine, do the following:
  - a. Select **Manage > Datasets**.
  - b. Select your PDB dSource.
  - c. From the **Actions** menu (...), select **Link dSource**.
  - d. In the Link dSource dialog, fill in the information corresponding to the new PDB dSource as well as its new environment:
  - e. Click **link**.

## Provisioning and managing virtual databases with Oracle

Each VDB has its own data management settings, found during the provisioning workflow as well as in the configuration page for that VDB. When you create a VDB, the Delphix Engine copies configuration settings from the dSource and uses them to create the VDB.

This section covers the following topics:

- [Overview of provisioning Oracle virtual databases](#)
- [Configuration settings for Oracle virtual databases](#)
- [Provisioning an Oracle VDB](#)
- [Provisioning an Oracle virtual pluggable database \(vPDB\)](#)
- [Provisioning a TDE-enabled vPDB](#)
- [Provisioning a vPDB from a non-multitenant source](#)
- [Provisioning a VDB from an encrypted Oracle database](#)
- [Refreshing and rewinding a TDE-enabled vPDB](#)
- [Timeflows for RAC provisioning of VDBs](#)
- [Upgrading an Oracle VDB, linked CDB, or a vCDB](#)
- [Customizing RAC instances after provision](#)
- [Migrating an Oracle VDB](#)
- [Migrating a vPDB](#)
- [Migrating a TDE-enabled vPDB](#)
- [Migrating a vPDB \(from a linked CDB\) to a higher Oracle version \(linked CDB\)](#)
- [V2P with an Oracle VDB](#)
- [Provisioning from a replicated Oracle VDB](#)
- [Provisioning a TDE-enabled vPDB to a cluster target](#)

## Overview of provisioning Oracle virtual databases

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment, as described in the overview for [Managing Environments and Hosts](#) and [Requirements for Oracle Hosts and Databases](#).

 A Solaris x86 source host is compatible with a Linux x86 target host and vice versa.

From a dSource, you can select a snapshot or point in time to create a VDB. Oracle VDBs each have their own configuration settings as described in [Configuration Settings for Oracle Virtual Databases](#)

### Procedure

1. In the Datasets panel on the left-hand side, click the group containing the dSource or VDB from which you want to provision.
2. From the **Timeflow** tab, select a snapshot or point in time to provision from.
3. Click to open the **Provision VDB wizard**, and select a compatible Target Environment for the new Oracle VDB
  - Select Provide Privileged Credentials if you want to use login credentials on the target environment that are different from those associated with the Environment User
4. In the **Advanced** section, you may customize the VDB’s configuration settings, file mappings, or custom environment variables.
  - For more information, see [Configuration Settings for Oracle Virtual Databases](#)
5. Select a **Snapshot Policy** for the VDB.
6. Enable **Masked Provisioning** by selecting an option on the Masking page.
7. Enter any operations that should be run in the Hooks page.
8. Review the VDB Configuration and Summary, and then click **Submit**.

When provisioning starts, you can review the progress of the job by selecting the VDB and clicking on the Status tab, or by selecting System and viewing the Jobs page.

Alternatively, you could see this in the Actions Sidebar. When provisioning is complete, the VDB will be included in the group you designated and listed in the Datasets panel.

### Provisioning by snapshot or logSync

When provisioning by snapshot, you can provision to the start of any particular snapshot, either by time or SCN.

#### Snapshot Options

Snapshot options	Description
Provision by Time	You can provision to the start of any snapshot by selecting that snapshot card from the TimeFlow view or by entering a value in the time entry fields below the snapshot cards. The values you enter will snap to the beginning of the nearest snapshot.

Snapshot options	Description
Provision by SCN	To open the SCN entry field select the Actions (...) menu for your selected snapshot and select View by SCN. Here, you can type or paste in the SCN to which you want to provision. After entering a value, it will "snap" to the start of the closest appropriate snapshot.

For more granularity, you can use the logSync options to provision to any point in time, or to any SCN, within a particular snapshot.

#### logSync Options

logSync options	Description
Provision by Time	Select Open logSync control to view the time range within that snapshot. Select the clock icon and then select Time to the point to the time from which you want to provision. You can also enter a date and time directly.
Provision by SCN	Select View SCN to view the range of SCNs within that snapshot. You can also type or paste in the specific SCN to which you want to provision. Note that if the SCN does not exist, you will see an error when you provision.

## Configuration settings for Oracle virtual databases

Each VDB has its own data management settings, found during the provisioning workflow as well as in the configuration page for that VDB. When you create a VDB, the Delphix Engine copies configuration settings from the dSource and uses them to create the VDB.

The following settings are available for Oracle VDBs:

VDB setting	Explanation
Mount base	The directory to which Delphix will provide mounted storage. This is where the contents of this VDB will be located.
VDB configure parameters	These are customizable parameters of the VDB that you can set either in the provided table or in the text field. This concept is described further below.
Open database after provision	<p>Open the VDB immediately after the provision completes. Enabling this option allows you to set the four parameters below:</p> <ul style="list-style-type: none"> <li>• Online Log Size (MB)</li> <li>• Number of Online Log Groups</li> <li>• Enable Archivelog Mode</li> <li>• Generate new DBID for VDB</li> </ul> <p>This setting is recommended to tune the Oracle database settings to match your requirements. Each of these four helps Delphix manage the Oracle database optimally.</p> <p>When provisioning an Oracle VDB with the "Open Database After Provision" option unchecked, the subsequent snapshot job fails because the database is not open. The UI will show that the provision failed, but this is not the case. A VDB provisioned this way will exist with the stop/start enable/disable function, but will need to be manually started on every refresh.</p>
Online log size (MB)	Also known as the online redo log, this specifies the size of the VDB's redo log. We recommend increasing this value to 1024 MB for improved performance.
Number of online log groups	The number of online log groups to be assigned to this VDB. The number of groups will depend on the configuration of your VDB. For more information, please visit <a href="#">Creating redo log groups and members</a>
Enable archivelog mode	When you enable this mode, redo logs will be archived instead of overwritten. This creates a backup of all transactions that have occurred in the database so that you can recover to any point in time. These archive logs are useful for recovering a database or updating a standby database.

VDB setting	Explanation
Generate new DBID for VDB	Create a new Oracle DBID value for this VDB. <b>Note: You can also toggle this option after VDB is created.</b> See <a href="#">Generate a new DBID for Oracle VDBs</a> and <a href="#">Toggle new DBID generation upon refresh options for Oracle VDBs</a>
Listeners	Select an Oracle listener from the list provided to use with this VDB.
Auto VDB restart	Enabling this option will automatically restart this VDB whenever its target host is rebooted. Auto VDB Restart can help you recover from host downtime automatically since the Delphix Engine will restart VDBs once they become available.
Configure File mapping	This option allows you to leverage Oracle's File Mapping feature with a VDB. Enabling this will add a step to the provisioning wizard to create file mappings.

Using Oracle Multitenant offers different configuration settings, as described in the table below:

Multitenant setting	Explanation
vCDB database parameters	vCDB Database Parameters are Oracle configuration settings you can apply during the provisioning process. You can specify name-value pairs to apply these settings to the vCDB if you are creating one.
Auto vCDB restart	Enabling this setting will automatically restart this vCDB whenever the target host is rebooted. This will cause all vPDBs in the vCDB to restart as well.

### VDB config templates

A VDB config template is a list of database configuration parameter names and values that you can save on the Delphix Engine to use at a later time.

#### Creating a VDB config template Via GUI

1. Log into the **Delphix Management** application as an engine administrator.
2. Click **Manage**.
3. Select **VDB Config Templates**.
4. Click the icon next to the **VDB Config Temp...** and select **New Template** to create a new template.
5. In the New Template dialog, enter the name for the new template, parameters that you want to provide, and select the source type from the available options.

## New Template ✕

6. Click **Create**.

#### Updating a VDB config template via GUI

1. Log into the **Delphix Management** application as an engine administrator.
2. Click **Manage**.
3. Select **VDB Config Templates**.
4. Select the template from the left-side pane that you need to update.
5. Click on the **pencil** icons to edit an existing VDB template.
6. Click the button to save the changes or click the button to discard the changes that you made.

#### Apply/Configure a VDB config template to a VDB Via GUI

1. Login to the **Delphix Management** application as an engine administrator.
2. Click **Manage > Datasets**.
3. Select the VDB you want to edit.
4. From the right-side pane select the **Configuration** tab.
5. Click on the **pencil** icon next to 'DATABASE' to be able to edit the database.

6. To apply an already existing VDB template, select from the available template in the drop-down under VDB Config Template. Similarly, you can configure the VDB for an already associated template from the available templates.

Timeflow	Status	Configuration
Source	Policies	Masking
<div style="border: 1px solid #ccc; padding: 10px;"> <p><b>Name</b> VDBO_OBA</p> <p><b>SID</b> VDBOMSRBBD COBA</p> <p><b>Version</b> Oracle 18.3.0.0.0</p> <p><b>Size</b> 2.12GB</p> <p><b>Archivelog Mode</b> On</p> <p><b>Online Logs</b> Each log is 1,024 MB, 3 log group(s) per Instance</p> <p><b>Auto VDB Restart</b> ⓘ <input checked="" type="checkbox"/> Enabled</p> <p><b>VDB Config Template</b></p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 5px;"> <p style="color: #0070c0;">No Template Selected</p> <p>test</p> </div> </div>		

7. Click the button to save the changes or click the button to discard the changes that you made.

You can apply a VDB Config Template to a VDB during the provisioning process, which copies the values from the template. Any subsequent changes to the template will be reflected in the VDB when that VDB is refreshed. During provisioning, you can specify configuration parameters directly or copy them from a VDB Configuration Template. Once set, the Delphix Engine will use these parameters whenever the VDB is refreshed, even if you change the original template. It is important to know, however, that some configuration parameters cannot be customized. In addition, some configuration parameters are stripped out during the provisioning process but are customizable. The list of restricted and customizable parameters can be found below.

**Required parameters**

The VDB configuration template must contain at least the following database parameters:

- **compatible** : Required for both Non-Multitenant and Multitenant sources. Must be set with the same value as in the dSource 'compatible' parameter.
- **enable\_pluggable\_database** : Required for Multitenant sources only. Must be set to TRUE.

#### Customizable VDB configure parameters

The default value for these parameters is cleared during the provisioning process. They are removed from the VDB configuration file unless you set values for them through a VDB Config Template.

- audit\_file\_dest
- audit\_sys\_operations
- audit\_trail
- background\_dump\_dest
- core\_dump\_dest
- db\_domain
- diagnostic\_dest
- dispatchers
- fast\_start\_mttr\_target
- log\_archive\_dest\_n
  - n can be values between 1 - 31
- log\_archive\_dest\_state\_n
  - n can be values between 1 - 31
- remote\_listener
- user\_dump\_dest

#### Restricted parameters

These parameters are restricted for use by the Delphix Engine. Attempting to customize these parameters through the use of a VDB Config Template will cause an error during the provisioning process.

- active\_instance\_count
- cluster\_database
- cluster\_database\_instances
- cluster\_interconnects
- control\_files
- db\_block\_size
- db\_create\_file\_dest
- db\_create\_online\_log\_dest\_n
  - n can be values between 1 - 5
- db\_file\_name\_convert
- db\_name
- db\_recovery\_file\_dest
- db\_recovery\_file\_dest\_size
- db\_unique\_name
- dg\_broker\_config\_file1
- dg\_broker\_config\_file2

### Automatic VDB restart on target server after reboot

The Delphix Engine now automatically detects whether a target server has been rebooted, and proactively restarts any VDB on that server that was previously up and running. This happens independent of the data platform; it is done as if a target server was restarted and a start command was issued from the Delphix Engine. This feature is compatible with Delphix Self-Service (Jet Stream) ordering dependencies and is limited to non-clustered VDBs.

**i** This feature is not supported for the following data source types:

- Oracle RAC VDBs
- Oracle 12.1 and older vPDBs that are provisioned into a non-virtual CDB.
- MSSQL cluster VDBs.

Automatic VDB Restart is supported for following Oracle data sources types:

- Non-Multi-Tenant (non-MT) VDBs
- Oracle 12c and later, vPDBs that are provisioned into a virtual CDB.
  - For Oracle 12.1.0.1, users can choose to enable or disable automatic restart at the virtual CDB level. There is no individual vPDB automatic restart setting.
  - For Oracle 12.1.0.2 and later versions, users can choose to enable or disable automatic restart for a virtual CDB or a virtual PDB.
- Oracle 12.2 and later vPDBs that are provisioned into a non-virtual CDB. Users can choose to enable or disable individual vPDB's automatic restart.

Please note, the scheduler checks every one minute if any VDB needs to be restarted. The Delphix Engine waits for five minutes after it detects a host has restarted before trying to restart VDBs. The engine will keep trying to restart the VDB for 30 minutes before giving up.

To enable automatic restart, complete the following steps:

1. When provisioning a new VDB in the VDB Provisioning wizard, check the **Auto VDB Restart** box.

#### Provision VDB

Generate a new DBID for Oracle VDBs

Delphix helps to generate a new Oracle internal database identifier (DBID) for VDBs. The DBID is an internal, unique identifier for an Oracle database.

**i** This feature is not supported for the following data source types:

- Multitenant VDB
- Oracle Live Source

Enable new DBID generation while provisioning a VDB

To enable generating a new DBID while provisioning a new VDB in the VDB Provisioning wizard, check the **Generate new DBID for VDB** option. This will create a new DBID for the provisioned VDB and subsequent refresh action performed to this VDB will get a different and new DBID.

Enable new DBID generation for an already provisioned VDB

If originally the VDB had been provisioned without specifying the **generate new DBID for VDB** option, then you can enable it so that new refreshes will create VDBs with a new DBID (Note the current VDB or previous VDBs will still have the same DBID as the original database). To accomplish this follow the steps below.

1. In the **Datasets** panel, select the **VDB**.
2. Select the **Configuration** tab.
3. Select **Source** sub-tab.
4. Select Database and click the **pencil** icon to edit.
5. Check the **Generate new DBID upon refresh** option.
6. Refresh the VDB to see the changes.

i If the **Generate new DBID upon refresh** option is enabled, then the Delphix engine will generate a new DBID upon refresh.

Disable new DBID generation for an already provisioned VDB

You can stop generating the new DBIDs for VDBs that were enabled for this at the time of provisioning or after provisioning. To accomplish this follow the steps below.

1. In the **Datasets** panel, select the **VDB**.
2. Select the **Configuration** tab.
3. Select **Source** sub-tab.
4. Select Database and click the **pencil** icon to edit.
5. Uncheck the **Generate new DBID upon refresh** option.
6. This will stop generating a new DBID for subsequent refreshes.
7. Refresh the VDB to reflect the changes.

**i** If the **Generate new DBID upon refresh** option is disabled, then the Delphix engine will use the same DBID of the parent upon refresh.

## Customizing Oracle VDB environment variables

### Overview

This topic describes how to customize the set of environment variables sourced prior to administering an Oracle virtual database (VDB). Certain Oracle database parameters are sensitive to the environment variables present when you start or administer the database. For this reason, the Delphix Engine allows you to dictate custom environment variables that will be set prior to any administrative action, such as provision, start, stop, rollback, or refresh.

You can specify environment variables by two different means:

- **Name-value pair** – A literal variable name and value to be set
- **Environment file** – An environment file to be sourced

Environment variables for Oracle RAC databases might vary in value between cluster nodes. Therefore, environment variable specifications for an Oracle RAC database must specify the cluster node to which they apply.

### Setting custom environment variables

#### Prerequisites

If you are adding any environment variables that are environment files, these files must be accessible on the target environment.

#### Procedure

1. You can configure custom environment variables in the **Provision Wizard**.
  - a. On the **Target Environment** tab, click **Advanced**. or
  - b. You can also configure these variables on the **Configuration tab** when the VDB is disabled.
2. Click the **Plus** icon to add an environment variable.
3. Choose a **format** for the environment variable.
  - a. Name-Value Pair
    - i. Enter a **Name** to identify the variable.
    - ii. Enter the variable's **Value**.
    - iii. For Oracle RAC databases, you must also specify the cluster node to which this environment variable applies.
  - b. Environment File
    - i. Enter an absolute path to an environment file on the target environment. This path can be followed by parameters. Paths and parameters are separated by spaces.  
Escaping Spaces  
To specify literal spaces, escape them with a backslash ("hello\ world" -> "hello world"). To specify literal backslashes, escape them with a backslash ("foo\" -> "foo"). Any other character preceded by a backslash will retain both the backslash and the original character ("\"b" -> "\b"). Escaping is done in order from left to right ("part1\ part2" -> "part1" "part2" will be two parameters).
    - ii. For Oracle RAC databases, you must also specify the cluster node to which this environment variable applies.
4. Save the custom environment variables by completing provisioning, or clicking the **Confirm**. These environment variables will take effect when you start the Oracle VDB.

#### Environment variable denylist

The Delphix Engine denylists the following environment variables; they cannot be set by the user.

- ORACLE\_SID

- ORACLE\_BASE
- ORACLE\_HOME
- CRS\_HOME
- ORACLE\_UNQNAME
- ORAENV\_ASK
- LOGON\_STR
- DLPX\_SHELL
- SQLPLUS\_PLSQL\_MODIFIERS
- SQLPLUS\_DML\_MODIFIERS
- SQLPLUS\_DDL\_MODIFIERS

If a Name-Value pair has any one of these prohibited environment variables as the name, an error will be raised.

If an environment file sets one of these variables, the Delphix Engine will override this value when the Oracle VDB is started.

The following environment variables will be set before invoking the user-specified script, and thus can be accessed within the script.

- ORACLE\_SID
- ORACLE\_BASE
- ORACLE\_HOME
- CRS\_HOME
- ORACLE\_UNQNAME

#### User-Input sanitation for environment variables

For security purposes, user-input provided through the custom environment variables feature retains its literal value when interpreted, including ', ', and undefinedORACLE\_HOME

- undefinedORACLE\_SID
- undefinedORACLE\_UNQNAME
- undefinedPATH

#### Caveats

- Environment variables are sourced on provision, start, stop, rollback, and refresh. Custom environment variables are not applicable to V2P.
- Custom environment variables do not propagate to child VDBs and must be set again on provision.
- Custom environment variables do not persist after migration. On migration of a VDB with custom environment variables, an alert will be raised that the custom environment variables have been removed from the VDB. In order to view the alert, go to **System > Event Viewer**.
- Custom environment variables are *not* available within scripts executed by VDB Hook Operations.

### Customizing VDB file mappings

This topic describes how to customize file path mappings when provisioning a virtual database (VDB).

In the VDB provisioning process, it may be necessary to create mappings between files and directories that exist on the source, and files or file directories that exist on the target. An example of this is creating a copy in the target environment of a wallet file for an encrypted database that exists in the source environment.

During VDB provisioning, the archive, datafile, external, script and temp directories are mounted from the Delphix Engine to the unique="">>

You can specify the Mount Base and the Database Unique Name on the Provision VDB card at provision time. But the archive, datafile, external, script and temp mount points are fixed.

- The default Mount Base is set to /mnt/provision
- The default Database Unique Name starts with a capital V and includes the dSource name

### Provision VDB

Mount Base: /mnt/provision

Database Unique Name: Vdbhcp3\_35F

Mounts: /mnt/provision/Vdbhcp3\_35F/archive

/mnt/provision/Vdbhcp3\_35F/datafile

/mnt/provision/Vdbhcp3\_35F/external

```
/mnt/provision/Vdbhcp3_35F/script
```

```
/mnt/provision/Vdbhcp3_35F/temp
```

File Mappings affect everything that follows the mount point directories above. For datafiles, the datafile location from the dSource is used. You can determine the directory structure by querying the Source database:

```
SQL> select name from v$datafile;
```

```
NAME
```

```
-----
```

```
/datafile/dbdhcp3/oradata/dbdhcp3/system01.dbf
```

```
/datafile/dbdhcp3/oradata/dbdhcp3/sysaux01.dbf
```

```
/datafile/dbdhcp3/oradata/dbdhcp3/undotbs01.dbf
```

```
/datafile/dbdhcp3/oradata/dbdhcp3/users01.dbf
```

```
/u03/app/ora11202/product/11.2.0/dbhome_1/dbs/dbv_R2V4.dbf
```

Users have control over the datafiles that were returned by the select name from v\$datafile and also the controlfile location.

Archive log files go directly into /mnt/provision/Vdbhcp3\_35F/archive

Tempfiles go directly into /mnt/provision/Vdbhcp3\_35F/temp

By default VDB File Mapping would append the above directory structure to the /mnt/provision/Vdbhcp3\_35F/datafile directory:

```
/mnt/provision/Vdbhcp3_35F/datafile/datafile/dbdhcp3/oradata/dbdhcp3/system01.dbf
/mnt/provision/Vdbhcp3_35F/datafile/datafile/dbdhcp3/oradata/dbdhcp3/sysaux01.dbf
/mnt/provision/Vdbhcp3_35F/datafile/datafile/dbdhcp3/oradata/dbdhcp3/undotbs01.dbf
/mnt/provision/Vdbhcp3_35F/datafile/datafile/dbdhcp3/oradata/dbdhcp3/users01.dbf
/mnt/provision/Vdbhcp3_35F/datafile/u03/app/ora11202/product/11.2.0/dbhome_1/dbs/
dbv_R2V4.dbf
```

Pattern matching example

You can use pattern matching rules to create full path names for data files and control files.

Pattern matching rules have the form **source-regex-expression-KEY : target-replacement-VALUE**. You can use multiple rules, which are applied successively. Multiple rules with the same source key are allowed.

#### File mapping options

##### Example 1

For this example, the ultimate goal is to create a VDB that has the following datafile File Mappings:

```
/u03/devvdb3/datafile/sys/system01.dbf
```

```
/u03/devvdb3/datafile/sys/sysaux01.dbf
```

```
/u03/devvdb3/datafile/ctrl/control01.ctl
```

```
/u03/devvdb3/datafile/undo/undotbs01.dbf
```

```
/u03/devvdb3/datafile/data/users01.dbf
```

```
/u03/devvdb3/datafile/data/dbv_R2V4.dbf
```

You can change the default behavior in a few different ways.

1. Modify the Mount Base.
2. Modify the Database Unique Name.
3. Modify the Mount Base and the Database Unique Name.
4. Modify the name of the individual subdirectories within the Mount Base/Database Unique Name/datafile directory.

Numbers 1-3 can be changed by simply modifying the Mount Base and/or Database Unique Name values when provisioning a VDB:

The datafile locations can be changed in the **Advanced** tab of the **Provision VDB** wizard and scroll down to **File Mapping**:

## Provision VDB

- Preparation
- Source
- Provision Point
- Target Environment
- Target Configuration
- Advanced**
- Policies
- Masking
- Hooks
- Summary

### Advanced

---

**Database After Provision**

Open Database After Provision

**Online Log Size (MB)**

**Number of Online Log Groups**

Enable Archivelog Mode

Generate new DBID for VDB

**Listeners**

LISTENER

**Auto VDB Restart** ⓘ

Enabled

**File Mapping**

Configure File Mapping

**Custom Environment Variables**

When you are changing File Mapping, remember that you only need to refer to the part of the path after /Mount Base/Unique Database Name/datafile.

Start by changing all the datafile locations from /u03/devvdb3/datafile/datafile/dbdhcp3/oradata/dbdhcp3 to /u03/devvdb3/datafile/data by selecting the + sign and setting **File Mapping Source File Match** and the **Replacement** and then select **Validate** to see result.

The result will show the new directory structure for all the datafiles and control file relative to the "/Mount Base/Unique Database Name/datafile" directory, but will only show the directories after the datafile directory.

Source File Match	Replacement	Result
/datafile/dbdhcp3/oradata/dbdhcp3	/data	/data/users.dbf

Selecting Validate will show the result of the above mapping, for all the datafiles.

The File Mappings build upon one another, so the first mapping moves almost all the datafiles and the controlfile to /u03//devvdb3/datafile/data.

/u03/app/ora11202/product/11.2.0/dbhome\_1/dbs/dbv\_R2V4.dbf was not remapped, as it did not contain the directory structure defined in in Source File Match (/datafile/dbdhcp3/oradata/dbdhcp3)

If you wanted the remaining datafiles and controlfile to remain in /data, it would only require the two File Mappings.

The remaining datafiles and controlfile can be relocated by adding to the mapping (select "+" between each Source File Match/Replacement pair).

/datafile/dbdhcp3/oradata/dbdhcp3/system01.dbf sys/system01.dbf	/sys/system01.dbf	/
--------------------------------------------------------------------	-------------------	---

/datafile/dbdhcp3/oradata/dbdhcp3/sysaux01.dbf sys/sysaux01.dbf	/sys/sysaux01.dbf	/
--------------------------------------------------------------------	-------------------	---

/datafile/dbdhcp3/oradata/dbdhcp3/undotbs01.dbf undo/undotbs01.dbf	/undo/undotbs01.dbf	/
-----------------------------------------------------------------------	---------------------	---

/datafile/dbdhcp3/oradata/dbdhcp3/control01.ctl ctrl/control01.ctl	/ctrl/control01.ctl	/
-----------------------------------------------------------------------	---------------------	---

Select Validate between each new entry **in** order to verify that datafiles are being mapped as expected.

Once all the files are located the way you want them, select **Next** to continue the provision process.

The **Summary** page will show the modifications to **Mount Base** and **Unique Database Name** and will show that **Customized File Mapping** was defined.

After provisioning completes, you can login to the Target server and verify that the datafiles were mapped correctly:

```
SQL> select name from v$datafile;
```

```
NAME
```

```
-----
```

```
/u03/devvdb3/datafile/sys/system01.dbf
```

```
/u03/devvdb3/datafile/sys/sysaux01.dbf
```

```
/u03/devvdb3/datafile/undo/undotbs01.dbf
```

```
/u03/devvdb3/datafile/data/users01.dbf
```

```
/u03/devvdb3/datafile/data/dbv_R2V4.dbf
```

### Example 2

In this example, several rules are applied to the source file path **/app/oracle/oradata/system01.dbf**.

1. Applying the rule **ora:foo** results in: **/app/foocle/foodata/system01.dbf**
2. Applying the rule **foo:bar** results in: **/app/barcle/bardata/system01.dbf**
3. Applying the rule **ora:no** results in an error, because **ora** is no longer found in the pathname.
4. Applying the rule **bar:orane** results in: **/app/orane**
5. Applying the rule **ora:yes** results in **/app/yesnewcle/yesnewdata/system01.dbf**

During the pattern matching process, two errors can be generated.

1. **No match for specified mapping rules** This is the result when no rules match a source file
2. **Invalid regex pattern specified for path mapping** This is the result of an invalid regex rule mapping

[This topic on the java.regex.util class](#), hosted on [docs.oracle.com](#), shows the regular expression syntax and constructs recognized by the Delphix Engine pattern-matching operations.

Applying VDB file mappings during the provisioning process

1. In the **Target Configuration** tab of the **Provision VDB** wizard, click **Advanced**.
2. Select **Configure File Mapping**.
3. Click **Next**.
4. Click the **Plus** icon to add a mapping rule.

Provision VDB

Find	Replace

5. Enter the mapping rule.
6. Click **Validate** to see the results of applying the rule. If not matches are found, you will see an error message.
7. Click **Next** to continue with the provisioning process.

## Manually starting a VDB

When starting an Oracle VDB instance, an initialization file `$ORACLE_BASE_CONFIG/dbs` is used and by default, this directory does not have group write permissions. Previously to Delphix 6.0.10.0, this limitation forced target hosts to either use the instance owner for provisioning or modify the group permissions on this directory. Both options can be seen as a security risk and increase deployment complexity.

With Delphix Engine 6.0.10.0 onwards, a target host no longer requires write permission to the `$ORACLE_BASE_CONFIG/dbs` directory. Delphix Engine will only copy an initialization file `init<>` to this directory if write permissions exist.

All instance startup attempts from Delphix operations will specify an initialization file to use from the Delphix filesystem rather than the default Oracle location. If a VDB needs to be manually started and Delphix was unable to copy the initialization then it must be specified in the startup command. The instance init file is available in the VDB script directory.

You can use the following syntax to manually start the instance:

```
SQL> startup pfile='/mnt/provision/VDBOMSR66E005_610/script/VDBOMSR66E0610/
initVDBOMSR66E0610.ora';
ORACLE instance started.
```

If there is no write permission in the `$ORACLE_BASE_CONFIG/dbs` directory then manually starting the instance will fail:

```
SQL> startup
ORA-01078: failure in processing system parameters
LRM-00109: could not open parameter file '/u01/app/oracle/product/11.2.0.4/dbhome_1/
dbs/initVDBOMSR66E0610.ora'
```

To manually start a VDB, complete the following steps:

1. Ensure that the VDB is enabled and NFS filesystems are mounted. This is required only when the NFS filesystems are offline. Follow the below steps via CLI.

```
demo source> select VDBOMSR66E005_610
demo source 'VDBOMSR66E005_610'> enable
demo source 'VDBOMSR66E005_610' enable *> set attemptStart=false
demo source 'VDBOMSR66E005_610' enable *> commit
  Dispatched job JOB-47
  SOURCE_ENABLE job started for "VDBOMSR66E005_610".
  Enabling dataset "VDBOMSR66E005_610".
  Exporting storage containers from the Delphix Engine.
  Mounting datasets.
  Dataset "VDBOMSR66E005_610" enabled.
  SOURCE_ENABLE job for "VDBOMSR66E005_610" completed successfully.
```

2. Login to the target host as a Delphix OS user.

3. Locate the VDB scripts directory. This is located at `<toolkit_directory>/Delphix_<engineuid>_<delphix_osuser_id>_<host|cluster>/databases/oracle/<vdb_uniq_name>/<vdb_instance_name>/.`

```
cd /work/Delphix_8e501f827dee_a7a9072fc4fe_2_host/databases/oracle/
VDBOMSR66E005_610/VDBOMSR66E0610
```

4. Run `setup-oraenv.sh`. This configures the Oracle environment variables such as ORACLE\_SID and ORACLE\_HOME.
5. Startup the instance by specifying the path to the instance init file in the scripts directory.

```
[oracle@mwrh74-ora11204-tgt VDBOMSR66E0610]$ sqlplus "/as sysdba"

SQL*Plus: Release 11.2.0.4.0 Production on Thu Jul 22 02:40:47 2021

Database opened.
SQL>
```

- [-] If Delphix Engine has permission to write to `$ORACLE_BASE_CONFIG/dbs` during provisioning, the instance can be started up with only the "startup" command.

## Provisioning an Oracle VDB

This topic describes how to provision a virtual database (VDB) from a dSource or another VDB.

 Masked Provisioning is supported on Oracle RAC only when used with "script-based masking".

### Prerequisites

- You must have already done one of the following:
  - linked a dSource from a source database, as described in [Linking an Oracle Data Source](#) or
  - created a VDB from which you want to provision another VDB
- You will need to have the correct OS User privileges on the target environment, as described in [Requirements for Oracle Target Hosts and Databases](#)
- If you want to use customized database configuration settings, first create a VDB Config Template as described in [Customizing Oracle VDB Configuration Settings](#)
- If you are creating a VDB from a dSource linked to an encrypted database, make sure you have copied the wallet file to the target environment, as described in [Provisioning a VDB from an Encrypted Oracle Database](#).

#### VDB configuration templates

It is recommended that you always create a VDB Configuration Template prior to provisioning a Virtual Database. This will allow you to customize your parameters for the initial provisioning, and ensure that subsequent changes are reflected on the VDB when refresh and rewind operations are run. See [Customizing Oracle VDB Configuration Settings](#) for more information.

 Once a VDB has been provisioned, archive logs, flashback logs, redo logs, and datafiles that are not known to be part of the database will be deleted when a SnapSync is performed on the VDB. As a result, make sure that no files are added to the `datafile` file system, as this is used by Delphix to store datafiles. Use the `external` filesystem for other files that are needed to be included in the snapshot that are not datafiles.

For example, creating a second control file on the `datafile` filesystem is prohibited. Such a file will be removed after SnapSync, rendering the VDB unusable. Similarly, block change tracking must not be enabled on a VDB.

### Procedure

- Login to the **Delphix Management** application.
- Select **Manage > Datasets**.
- In the **Datasets** panel on the left-hand side, click the **group** containing the dSource or VDB from which you want to provision.
- Click the **TimeFlow** tab.
- Select a **snapshot**.  
For more information on provisioning options.  
**Info** : You can take a snapshot of the dSource from which to provision. To do so, click the **Camera** icon.
- Optional:** Select  to open LogSync timeline.

7. Select  to provision from a point of time within a snapshot. You can select by date or time.
8. Click  and the **Provision VDB** wizard will open:
  - a. For **Oracle Single Instance** the fields **Installation Home, Database Unique Name, SID, Database Name, Mount Base, and Environment User** will auto-populate with information from the parent.
  - b. For **Oracle RAC** the fields **Installation Home, Database Unique Name, SID, Database Name, Mount Base, Instance Number, Instance Name** and **Environment User** will auto-populate with information from the parent.

**Note** : Editable Fields in the VDB Provision Wizard  
 The following fields are editable:  
 Installation Home (need to have an additional compatible target)  
 Database Unique Name  
 SID  
 Database Name  
 Mount Base  
 Instance Number (RAC Only)  
 Instance Name (RAC Only)
9. If you need to add a new target environment for the VDB, click the green **Plus** icon next to the **Filter Target** field, and follow the instructions in [Adding an Oracle Single Instance or RAC Environment](#)
10. Review the information for **Installation Home, Database Unique Name, SID, and Database Name**. Edit as necessary.
11. Review the **Mount Base** and **Environment User**. Edit as necessary. The Environment User must have permission to write to the specified Mount Base, as described in [Requirements for Oracle Target Hosts and Databases](#). You may also want to create a new writeable directory in the target environment with the correct permissions and use that as the Mount Base for the VDB.

12. Select **Provide Privileged Credentials** if you want to use login credentials on the target environment that are different from those associated with the **Environment User**.
13. Click **Advanced** to customize the VDB online log size and log groups, archivelog mode, local\_listener parameter (TCP/IPC protocol addresses), additional VDB configuration settings or file mappings, or custom environment variables. If you are provisioning to a target environment that is running a Linux OS, you will need to compare the `SGA_TARGET` configuration parameter with the shared memory size in `/dev/shm`. The shared memory configured on the target host should match the SGA memory target. You can check the Linux OS shared memory size with the command `df -k /dev/shm` and the `SGA_TARGET` configuration parameter by opening the **Advanced** settings and then finding the value for `SGA_TARGET` under **VDB Configuration Templates**.
14. Click **Next**.
15. Select a **Target Group** for the VDB.
16. Enable Auto VDB Restart to allow the VDB to be automatically restarted when the target host reboot is detected by Delphix.  
**Note** : The **Auto VDB Restart** feature is currently not available for Pluggable Databases, Clusters, or LiveSource.
17. Click Next.
18. Select a **Snapshot Policy** for the VDB.
19. Click **Next**.
20. Enter any operations that should be run at Hooks during the provisioning process.
21. Click **Next**.
22. Click **Submit**.

When provisioning starts, you can review the progress of the job by selecting the VDB and clicking on the **Status** tab, or by selecting **Manage/Dashboards** and viewing the **Job History** panel. Alternatively, you could see this in the **Actions Sidebar**. When provisioning is complete, the VDB will be included in the group you designated and listed in the **Datasets** panel. If you select the VDB in the **Datasets** panel and click the **Configuration** tab, you can view information about the database and its Data Management settings.

Provisioning by snapshot or LogSync

Refer to [Overview of Provisioning Oracle Virtual Databases](#)

Adding or removing RAC VDB cluster node after a VDB is provisioned

Prerequisites

- Disable the VDB before you edit the instance configuration.

Procedure

After provisioning:

1. Click the **group** containing the VDB.
2. Click the **VDB**.
3. Disable the VDB in order to make changes to instance configuration.
4. Under **Configuration > Source** click the **edit** button and edit the following:
  - a. **Instance Number** for each corresponding instance
  - b. **Instance Name**
  - c. Check or uncheck the cluster nodes you want for this RAC VDB
5. Click the check button to save changes.
6. Enable the VDB to apply the instance configuration changes.

## Provisioning an Oracle virtual pluggable database (vPDB)

In the Oracle multitenant architecture, there are two main database types: container databases (CDBs) and pluggable databases (PDBs).

 Source CDBs containing Application Container PDBs are currently not supported.

The process of creating virtual pluggable databases is similar to creating non-multitenant virtual databases, with a few additional steps necessary in the multitenant architecture.

 A Solaris x86 source host is compatible with a Linux x86 target host and vice versa.

Delphix supports provisioning Oracle Virtual Pluggable Databases (vPDBs) in two configurations:

1. **Linked container databases (Linked CDBs):** Physical CDBs that have been previously provided by the Oracle DBA on the target environment to which Delphix may provision vPDBs. Physical CDBs must be configured and set up specifically for use by Delphix.
2. **Virtual container databases (vCDBs):** vCDBs are created by Delphix during the provision workflow for vPDBs. Once created for Oracle versions 12.1.0.2 and later, it may be used to provision additional vPDBs.

Prerequisites for provisioning a vPDB to a linked CDB

There must be a target environment that has an Oracle installation compatible with the Oracle installation of the source CDB and the source PDB. The following database requirements are needed to provision the vPDB to a linked CDB. For more information, see [Requirements for Oracle Hosts and Databases](#)

- Recommend autodiscovery so that the linked CDB can be found. Otherwise, the linked CDB must be manually discovered before provisioning.
- Linked CDB must be running
- Linked CDB must be in ARCHIVELOG mode
- Linked CDB should be using Block Change Tracking (BCT)
- LogSync must be enabled for the Linked CDB.

Provisioning a vPDB to a linked CDB

For provisioning a vPDB into a Linked CDB, the source CDB and the target CDB must meet the following compatibility requirements:

- The value of the COMPATIBLE parameter in the source CDB must be less than or equal to the value of the COMPATIBLE parameter in the target CDB
- They must have the same endianness
- They must have compatible character sets and national character sets
- They must have the same set of database options installed. For example, if the source CDB is a real application cluster (RAC) database, the target CDB must be a RAC database.

Setting up auxillary CDB parameters

During a vPDB provisioning into a Linked CDB, the Delphix Engine creates a temporary CDB instance on the target environment to recover the vPDB to a consistent state. This temporary CDB will be automatically deleted after the vPDB is provisioned successfully. By default, this temporary CDB is configured to have the same init parameters as the source database. To manage the configuration of the temporary CDB, you must set up [Repository Templates for Oracle Databases](#) during provisioning.

## Provisioning a vPDB to a new or an existing vCDB

When provisioning a vPDB into a new vCDB:

- Delphix will provision a virtual CDB (vCDB) from the source CDB to host the vPDB you are about to create.
- There is no need to set up a repository template, as this provision workflow allows a user to directly specify a VDB configuration template, or set individual database parameters.

### Procedure

1. In the **Datasets panel**, select an Oracle PDB dSource or a previously provisioned vPDB.
2. From the **Timeflow** tab, select a snapshot or point in time to provision from.
3. Once the Provision wizard is open, you can either provision with a:
  - Target Linked CDB: Select an existing container database as the provision target CDB from the **Container Database** drop-down menu of CDBs on that environment.
  - Existing vCDB: Select an existing vCDB as the provision target CDB from the **Container Database** drop-down menu of CDBs on that environment. (Supported only for Oracle versions 12.1.0.2 and later.)
  - New vCDB: Select the **Create a New Container Database** checkbox. This will create a new vCDB object in that environment with this new vPDB plugged into it.
4. Click **Next** to advance the left-hand pane to the **Target Configuration** tab, and edit as necessary.
5. The Environment User must have permission to write to the specified Mount Base, as described in [Requirements for Oracle Environments and Data](#). You can also reuse the Delphix toolkit directory, which already exists as the Mount Base, or create a new writable directory in the target environment with the correct permissions and use that as the Mount Base.
6. Enter the vPDB Name, Target Group for the vPDB you are about to provision.
7. If you selected to create a new target vCDB, configure the vCDB:
  - Enter the vCDB Name, Database Unique Name, and Database Name for the vCDB you are about to provision.
  - Select the Configure vCDB Parameters checkbox if you want to use a VDB Configuration Template. See [Customizing Oracle VDB Configuration Settings](#)
8. Click **Next** to advance the left-hand pane to the Advanced tab.
9. The available options are Auto vCDB Restart, Auto vPDB Restart, File Mapping, and custom environment variables. For more information, see [Customizing VDB File Mappings](#) and [Customizing Oracle VDB Environment Variables](#)
10. Click **Next** to advance the left-hand pane to the Policies tab.
11. Select the VDB Snapshot policy to be applied to the vPDB. Select a Retention Policy for the vCDB, if you are provisioning a vCDB.
12. Click **Next** to advance the left-hand pane to the Masking tab. Select the Mask this vPDB checkbox if you want to mask, and select the masking job to be applied.
13. Click **Next** to advance the left-hand pane to the Hooks tab, and create any hooks if necessary. For more information, see [Hook Scripts for Automation and Customization](#)
14. Review the provisioning summary. Click **Submit** to proceed with provisioning the vPDB.

## Provisioning a TDE-enabled vPDB

### Overview

Provisioning a Virtual Pluggable Database (vPDB) first involves using the GUI or CLI to specify the vPDB parameters (such as the vPDB name and target container) along with the snapshot to provision from. Once the provision job is started with these parameters, the Delphix Engine does the following:

1. Mounts the snapshot files on the target host.
2. Creates and opens (in mount mode) the auxiliary container database on the target host, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.
3. Completes recovery to bring the auxiliary container database into a consistent state.
4. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
5. Plugs the vPDB into the target database, and opens it in read-write mode for general use.

If the dSource is TDE-enabled, then Delphix will need to perform additional operations to complete the provision of a TDE-enabled vPDB to a TDE-enabled target container (indicated in **red**):

1. Mounts the snapshot files on the target host.
2. Creates a keystore with the necessary keys to apply encrypted archived log files.
3. Creates and opens (in mount mode) the auxiliary container database on the target host, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.
4. Completes recovery to bring the auxiliary container database into a consistent state.
5. Rotates the vPDB and auxiliary CDB master encryption keys by generating new keys that are unique to the vPDB / auxiliary CDB and not associated with the source PDB or CDB.
6. Exports only the newly generated keys to an exported keyfile to enable unplug.
7. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
8. Imports the keys from the exported keyfile into the target keystore.
9. When provisioning to a vCDB target, converts the auxiliary CDB into the final vCDB and creates the vCDB keystore from the auxiliary CDB keystore.
10. Plugs the vPDB into the target database, and opens it in read-write mode for general use.

If the initial provision of a TDE-enabled vPDB to a vCDB has either failed or been canceled before step 9, which creates the vCDB Keystore, refreshing that vPDB will fail because there is no target Keystore to merge into the auxiliary CDB Keystore for use during recovery. In this case, it will be necessary to delete the failed/canceled vPDB and provision again. This does not apply when provisioning to a linked target CDB, which will already have its own Keystore configured.

The following diagram illustrates the provisioning steps.

At each stage of the provisioning process, the keys and exported keyfiles are always on user storage. The exported keyfile is located in the artifact directory, while the auxiliary and target keystores are in the auxiliary keystores directory. Both the artifact directory and auxiliary keystores directory are subdirectories of the TDE keystores root directory, which is either user specified, or if not specified defaults to the toolkit root directory. As for non-TDE-enabled vPDBs, the final vPDB (and vCDB, if applicable) is on Delphix storage while the target linked CDB and its archive logs remain on user storage.

### Provisioning a TDE-enabled vPDB

To initiate the provision, Delphix needs the following pieces of information, all of which can be specified in the GUI or CLI:

Parameter	Description	CLI Parameter	Required?
Parent keystore path	Path to a keystore that contains the keys used to encrypt the dSource datafiles. This keystore must be located on the target system. It does not have to be in the location specified by <code>sqlnet.ora</code> or <code>wallet_root</code> , but can be for consistency. It cannot be located on an ASM filesystem. This parameter can be updated if the path is changed.	source.parentTdeKeystorePath	yes
Parent keystore password	Password for the parent keystore. This parameter can be updated if the password is changed.	source.parentTdeKeystorePassword	yes
Exported keyfile secret	When exporting keys to a keyfile from a keystore, Oracle requires a password to be set. Once specified, this cannot be changed for the life of the vPDB.	source.tdeExportedKeyfileSecret	yes
Target keystore password	Password for the target keystore. This parameter can be updated if the password is changed.	sourceconfig.tdeKeystorePassword	yes
Keystores root directory path	Path to a directory on the target host under which all Delphix related TDE artifacts will be created. This includes keystores used by the auxiliary CDB during provisioning and the artifact directories for TDE-enabled vPDBs.	host.oracleParameters.tdeKeystoresRootPath	yes for cluster targets, optional for single instance targets

Parameter	Description	CLI Parameter	Required?
Target vCDB TDE Keystore Location	Path of the location at which Delphix will create the keystore for vCDB provision jobs. This keystore must be located on the target system. For Oracle 12.2 the path must match what is specified by sqlnet.ora. For higher versions, Delphix will set the <code>wallet_root</code> parameter to the provided location. This parameter must be updated if the keystore location is changed or else future Delphix operations may fail.	<code>source.targetVcdbTdeKeystorePath</code>	yes for vCDB targets. Not applicable to linked CDB targets
Target vCDB TDE Keystore Password	Password for the vCDB keystore. This parameter can be updated if the password is changed.	<code>virtualCdb.sourceConfig.tdeKeystorePassword</code>	yes for vCDB targets. Not applicable to linked CDB targets

Adding or editing the target keystore password

The target keystore password is specified in the GUI in the Databases tab under Environments:

1. Login to the **Delphix Management** application.
2. Click **Manage > Environments**.
3. Click the **Databases** tab for your Environment.
4. Next to **TDE Keystore Password** click on the pencil icon to set or update the password.

Adding or editing the keystores root directory path

The keystores root directory path is specified in the GUI in the Details tab under Environments:

1. Login to the **Delphix Management** application.
2. Click **Manage** → **Environments**.
3. Click the **Details** tab for your Environment.
4. Next to **Attributes** click on the pencil icon to set or update attributes, including the keystores root.

Once a TDE-enabled vPDB is provisioned, it can be used the same as a non-TDE-enabled vPDB within Delphix, with the exception of [migrate](#). There are however a few caveats:

- A refresh operation will use the parent keystore for the recovery. If the dSource is rekeyed then the user will need to update the parent keystore with the new keys. Similarly, if the location or password to the parent keystore has changed then they should be updated before the refresh.
- A rewind operation will use the target keystore for the recovery. If the vPDB is rekeyed after it is provisioned, then the rekey will update the target keystore, so it does not need to be updated in Delphix.
- For a single vPDB in a vCDB, if the vCDB keystore location is changed, the new path must be updated in Delphix before refresh or rewind.
- Each disable operation will result in the keys being exported to an exported keyfile in the artifact directory, to be used for a subsequent enable. Refresh and rewind operations will first disable the existing vPDB, so those will also result in a new exported keyfile in the artifact directory.
- Provisioning a second-generation vPDB (vvPDB) from a TDE-enabled vPDB is done in the same manner as a first-generation vPDB, by specifying the TDE parameters during provision. The current keystore for the vPDB can be specified as the parent keystore.

Example illustrating movement of keys

Consider the example illustrated by the vPDB provision above. The vPDB tde\_vpdb is provisioned from the dSource CDOMSHSR52CAPDB2 on the VM tde-source18, which is an Oracle database running version 18.11.0. Connecting to this database, we can query `v$encryption_keys` to determine the current keys in use by each PDB:

```
SQL> show pdbs
CON_ID CON_NAME                OPEN MODE  RESTRICTED
-----
 2 PDB$SEED                    READ ONLY NO
 3 CDOMSHSR52CAPDB1           READ WRITE NO
 4 CDOMSHSR52CAPDB2           READ WRITE NO
 5 CDOMSHSR52CAPDB3           READ WRITE NO
SQL> select con_id, key_id from v$encryption_keys order by con_id;

CON_ID KEY_ID
-----
 1 Ac9MY5kQwU8GvwLYMXImXmMAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 3 AedrXL3aUk9zv+9t7J8ZsVYAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 4 AdDdKibLKU9mv6PDAlvVvH0AAAAAAAAAAAAAAAAAAAAAAAAAAAA
 5 AWdc3ZRaP09Pvw4+2FmLwHAAAAAAAAAAAAAAAAAAAAAAAAAAAA
```

The `v$encryption_keys` output for this environment shows that there are 3 PDBs within this CDB, all of which are TDE-enabled. In particular, the PDB used for the dSource has a `con_id` of 4, and an encryption key starting with **AdDdKibL**.

The vPDB tde\_vdb is provisioned to the CDB CDOMSHTG93CF on the VM tde-target18. Connecting to this database, we can again query `v$encryption_keys` to determine the keys in use by each PDB:

```
SQL> show pdbs
CON_ID CON_NAME                OPEN MODE  RESTRICTED
-----
 2 PDB$SEED                    READ ONLY NO
 3 CDOMSHTG93CFPDB1           READ WRITE NO
 4 CDOMSHTG93CFPDB2           READ WRITE NO
 5 CDOMSHTG93CFPDB3           READ WRITE NO
 6 TDE_VPDB                    READ WRITE NO
SQL> select con_id, key_id from v$encryption_keys order by con_id;

CON_ID KEY_ID
-----
 1 AZTc9eKq1k98v8GkQ8/AmaAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 6 AdDdKibLKU9mv6PDAlvVvH0AAAAAAAAAAAAAAAAAAAAAAAAAAAA
```

The key which was originally present in the wallet on the dSource - **AdDdKibL** - has been imported into the target keystore, and has a `con_id` of 6, which corresponds to the `con_id` of the vPDB. There are several things to note about the behavior of Oracle and the `v$encryption_keys` table:

1. Keys are never deleted from existing keystores by Oracle, only new keys are added. Therefore, if we were to disable the vPDB, which will unmount and unplug it from the CDB, `v$encryption_keys` will still show the key as present, with its original `con_id`, even though it has been unplugged:

```

SQL> show pdbs
CON_ID CON_NAME          OPEN MODE  RESTRICTED
-----
 2 PDB$SEED             READ ONLY  NO
 3 CDOMSHTG93CFPDB1   READ WRITE NO
 4 CDOMSHTG93CFPDB2   READ WRITE NO
 5 CDOMSHTG93CFPDB3   READ WRITE NO
SQL> select con_id, key_id from v$encryption_keys order by con_id;
CON_ID KEY_ID
-----
 1 AZTc9eKqlk98v8GkQ8/AmaAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 6 AdDdKibLKU9mv6PDAlvVvH0AAAAAAAAAAAAAAAAAAAAAAAAAAAAAA

```

2. If the wallet is closed for a particular PDB, `v$encryption_keys` will not show any entries for that PDB. The wallet status can be determined by querying `v$encryption_wallet`.
3. Querying `v$encryption_wallet` while the session is attached to CDB\$ROOT will return information about the entire CDB, otherwise, only the keys for the current PDB are returned.

#### TDE keystores root and artifact directory

The artifact directory stores the exported keyfiles used during the workflows for TDE-enabled vPDBs. It is located under the keystores root, in the directory `oracle_tde_keystores`. Each TDE-enabled vPDB will have its own directory within the `oracle_tde_keystores` directory, identified by the vPDB name, group name, and a unique identifier, separated by an underscore. If the keystores root directory is not specified, then it defaults to the toolkit directory path.

For example, if the keystores root directory is `/work` (or keystores root is not specified, and the toolkit directory is `/work`), the artifact directory for the vPDB `tde_vpdb` in the group `Encrypted` could be

```
/work/oracle_tde_keystores/tde_vpdb_Encrypted_ce7a47e6-8860-4398-bab0-cf0233fc5e3c
```

Within the artifact directory, there is a subdirectory `exported_keys` which contains within it the exported keyfiles for each timeflow associated with that vPDB. Each time an export is performed, a new exported keyfile is generated with a timestamp. The contents of the artifact directory may change for future releases, but the path to the artifact directory and the naming convention is not anticipated to change.

As the default keystores root directory `root` is at the same level as the toolkit directory, it will not be overwritten if a host is refreshed through the Delphix Engine and the toolkit updated. It is the customer's responsibility to maintain the artifact directory and ensure that the contents are not lost, as a disk failure could prevent a TDE-enabled vPDB from being accessed. Thus it is recommended that the keystores root directory be on a disk which is regularly backed up.

If a vPDB is moved to a different host (either through the migrate workflow or an enable after a failover, then the artifact directory will need to be copied to the new target host. See [Migrating a TDE-enabled vPDB](#) for details on the manual steps needed for migration.

The artifact directory is not removed when a TDE-enabled vPDB is deleted; the customer can remove it after confirming that the vPDB has been removed (including from any replicated Delphix Engines).

## Provisioning a vPDB from a non-multitenant source

Delphix supports provisioning a virtual pluggable database (vPDB) from a snapshot of a non-multitenant (non-MT) source database (VDB). This feature is only available through the API or command-line interface (CLI). This topic describes how to provision a vPDB from a snapshot of a non-MT VDB (also simply referred below as source VDB) using CLI.

The high-level workflow for the provisioning is as follows:

 This feature has the following restrictions:

1. Transparent Data Encryption (TDE) is not supported.
2. The provision point must correspond to a snapshot. Provisioning from a point in time between snapshots is not supported.
3. The target CDB (where the new vPDB will be plugged into) must be a physical CDB. Virtual CDB targets are not supported.
4. For provisioning from a source VDB of Oracle 11g version, the VDB must be upgraded before provisioning (i.e. you must use the Upgrade Option 1 described below). Upgrade option 2 cannot be used in this case.

- Choose the upgrade option to use if the target CDB (where the new vPDB will be plugged into) version is newer than the source VDB. Refer to the prerequisites section below.
- Create the required hook scripts.
- Take source VDB snapshot.
- Provision the vPDB to the target CDB using the VDB snapshot.

### Prerequisites

#### Environment requirements

Provisioning a vPDB from a non-MT source has the following environment requirements:

- Source host with a non-MT Oracle 11g or newer source database.
- VDB Target host for provisioning a non-MT VDB from the source database.
- CDB target host with a running Oracle target version CDB. The target CDB will be automatically linked if it is not already linked.

#### Select upgrade option

The target CDB can be a newer Oracle version than the source database (for example, the source is 12.2 and target is 19c). When an upgrade is also required, there are two options for upgrading the database:

- **Upgrade Option 1:** After source VDB is provisioned and before vPDB is provisioned via CLI. This upgrade is done manually by the user, before initiating the vPDB provisioning API/CLI. This option requires the ability to upgrade to the Oracle target version on the VDB target host.
  - **Upgrade Option 2:** After plugging the newly provisioned vPDB into the target CDB database. This upgrade is performed by Delphix API/CLI using a hook script.
- If the source VDB's Oracle version is 11g, Upgrade Option 1 must be selected. For source VDB's with Oracle versions 12c and above, either option may be selected.

#### Prepare hook scripts

There are following three scripts used during this procedure and must be created manually before executing the vPDB provisioning command by CLI:

1. **Pre-snapshot Hook on source VDB:** This hook will open the database in "read only" mode and issue a call to the `dbms_pdb.describe` procedure to generate an XML file called `delphix_plugin.xml`, describing the VDB. The XML file will be used to plug the source VDB data files into the target CDB. The source VDB must be open read only during the subsequent snapshot so that the VDB data files do not require recovery when plugging them into the target CDB. This can be added using Delphix Management Application UI from the Datasets panel by selecting the source VDB and then going to Configuration -> Hooks tab.
2. **Post-snapshot Hook on source VDB:** This hook will return the VDB to "read write" mode. This is an optional script. The source VDB can also remain read only. This can be added using Delphix Management Application UI from the Datasets panel by selecting the source VDB and then going to Configuration -> Hooks tab.
3. **Post-plug Hook for vPDB:** This script will run as a hook present on the Linked CDB target host and will be executed after the newly provisioned vPDB is plugged into the target CDB.
  - a. If no upgrade is required or using Upgrade Option 1, then this script will call the Oracle script `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` to convert the VDB into a PDB.
  - b. If using Upgrade Option 2, this script will upgrade the database and then call Oracle script `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql`.

This script must be created manually and stored in the root folder of the Delphix Toolkit directory of the target CDB host. The name of the vPDB being provisioned/converted will be supplied by Delphix as the first parameter to the script when it invokes the script. The VDB data files will already be plugged into the Linked CDB target at the time the script is invoked.

Refer to the [Sample Scripts](#) section below for the content of scripts.

 Note about the sample scripts provided in this document:

- These scripts are provided as-is, without warranty of any kind or commercial support through Delphix.
- The scripts may need to be modified depending on the Oracle version or the SQL script package version being used.

## Workflow

1. Link the non-MT source database as a dSource within Delphix.
2. Provision a non-MT Oracle VDB from the dSource onto the VDB target host. This will be referred to as the **Golden VDB**.
3. **If no upgrade is required:** a. Create a [Pre-snapshot hook](#) on the **Golden VDB**. b. (Optional) Create a [Post-snapshot hook](#) on the **Golden VDB**. c. Take a snapshot of the **Golden VDB**. d. Create a [PDB conversion script](#) named `dx-post-plug-hook.sh` in the root of the Delphix toolkit directory of the Linked CDB target host.  
**If using Upgrade Option 1:** a. Upgrade the **Golden VDB** to the Oracle target version: manually upgrade the database and point it to the new Oracle home. b. Create a [Pre-snapshot hook](#) on the **Golden VDB**. c. (Optional) Create a [Post-snapshot hook](#) on the **Golden VDB**. d. Take a snapshot of the **Golden VDB**. e. Create a [PDB conversion script](#) named `dx-post-plug-hook.sh` in the root of the Delphix toolkit directory of the Linked CDB target host.  
**If using Upgrade Option 2:** a. Create a [Pre-snapshot hook](#) on the **Golden VDB**. b. (Optional) Create a [Post-snapshot hook](#) on the **Golden VDB**. c. Take a snapshot of the **Golden VDB**. d. Create a [PDB Upgrade and Conversion script](#) named `dx-post-plug-hook.sh` in the root of the Delphix toolkit directory of the Linked CDB target host.
4. Select the **snapshot** on the **Golden VDB** created above and provision a vPDB to the Linked CDB target. The detailed steps for this are documented in the next section.

 This step can be executed via the **API / CLI only**, and will not be allowed via the Delphix UI.

#### CLI procedure to provision a vPDB from a VDB

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
$ ssh admin@YOUR_ENGINE
```

2. Move to the database provisioning command line object.

```
delphix> database provision
```

3. Set the parameter type to `OracleMultitenantProvisionParameters`.

```
set type=OracleMultitenantProvisionParameters
```

4. (Optional) Set the login details for the provision and Delphix OS user who is to perform the provision.

```
delphix database provision *> set username=delphix
delphix database provision *> set credential.type>PasswordCredential
delphix database provision *> set credential.password=delphix
```

5. Give the dataset a name.

```
delphix database provision *> set container.name=vpdb
```

6. Place the new dataset in a Group that appears in the Delphix GUI, in this case, the Targets group.

```
delphix database provision *> set container.group=Targets
```

7. Set the destination mount point which Delphix NFS mounts are to be linked to under the virtual PDB. This folder must exist at a file system level on the Linked CDB target host. Do not use single quotes around the mount path.

```
delphix database provision *> set source.mountBase="/mnt/provision"
```

8. If automatically restarting the vPDB is not required after a reboot of the Linked CDB target host, set this to option to false. False is possibly a better option given the container database would need to be running prior to any attempt to pull up a vPDB.

```
delphix database provision *> set source.allowAutoVDBRestartOnHostReboot=false
```

9. Supply the destination container database name. The container database should already be discovered. This will be where the vPDB will ultimately be placed.

```
delphix database provision *> set sourceConfig.cdbConfig=CDBSTAGE
```

10. Name the vPDB. This is what it will appear as in the destination container database.

```
delphix database provision *> set sourceConfig.databaseName=vpdb
```

11. Supply the source **Golden VDB** details. In this example, the provision will use the latest snapshot available from the **Golden VDB** as the point in time from which to provision the vPDB. A specific snapshot can also be picked, but an arbitrary point in time is not supported.

```
delphix database provision *> set timeflowPointParameters.type=TimeflowPointSemantic delphix database provision *> set
```

```
timeflowPointParameters.container=gold_vdb delphix database provision *> set timeflowPointParameters.location=LATEST_SNAPSHOT
```

12. Check that all the settings you require are in place using the "ls" command.

```
delphix database provision *> ls

defaults

13. Initiate the provision by committing the operation in the CLI.

```

delphix database provision *> commit
vpdb
Dispatched job JOB-333
DB_PROVISION job started for "Targets/vpdb".
Starting provision of virtual PDB database "vpdb" converted from a single
tenant database.
Preparing multitenant container database "CDBSTAGE".
Creating new TimeFlow.
Generating recovery scripts.
Exporting storage.
Preparing XML manifest file prior to plugin.
Plugging in Oracle pluggable database.
Running user-defined post plug hook.
Opening Oracle pluggable database.
Setting OMF destination for Oracle pluggable database.
Creating PDB tempfiles.
Checking Oracle pluggable database plugin violations.
DB_PROVISION job for "Targets/vpdb" completed successfully.

```

- i** To refresh the data in the vPDB from production, first, refresh the **Golden VDB** from the dSource, then refresh the vPDB from the new snapshot in the **Golden VDB**.

There are some workflow customizations required for RAC databases:

1. The PDB conversion script must be in the root of the Delphix toolkit directory for all the target CDB RAC instances.
2. The **Golden VDB** Pre-Snapshot hook, as provided below, will not work in a clustered (RAC) environment with more than one active instance because it only shuts down the local instance. `dbms_pdb.describe` will not execute while an instance is open read-write. The workarounds are:
  - a. Provision the **Golden VDB** as single-instance, either by provisioning to a non-RAC target or by provisioning to a RAC target with only one active instance. The sample hook will work in this case.
  - b. Write a customized pre-snapshot hook that shuts down all instances, restarts only one instance in read-only mode, and runs `dbms_pdb.describe`.
  - c. Manually perform the actions of the hook: shutdown the **Golden VDB**, restart one of the instances in read-only mode and then run `dbms_pdb.describe`.

## Sample scripts

### Golden VDB pre-snapshot hook

Restarts the source/Golden VDB in read only mode and runs `dbms_pdb.describe` to generate an XML file describing the VDB. The XML file will be used to plug the VDB into the Linked CDB target. The target for the XML file must be `$DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/delphix_plugin.xml`.

```
#!/bin/sh

sqlplus "/ AS SYSDBA" <<-EOF
  whenever sqlerror exit 2;
  spool $DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/presnapshot.out
replace
  shutdown immediate
  startup mount
  alter database open read only;
  exec dbms_pdb.describe(pdb_descr_file=>'$DELPHIX_MOUNT_PATH/
$DELPHIX_DATABASE_UNIQUE_NAME/datafile/delphix_plugin.xml');
  exit;
EOF
```

### Golden VDB post-snapshot hook

This is only necessary if the source VDB should not be left in read-only mode after the snapshot.

```
#!/bin/sh

sqlplus "/ AS SYSDBA" <<-EOF
  whenever sqlerror exit 2;
  spool $DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/postsnapshot.out
replace
  shutdown immediate
  startup
  exit;
EOF
```

### PDB conversion script

This script converts the source/Golden VDB datafiles into PDB datafiles. The script should be named `dx-post-plugin-hook.sh` and reside in the root of the Delphix toolkit directory of the Linked CDB target host. Delphix will supply the name of the PDB being provisioned/converted as the first parameter.

The VDB datafiles will have already been plugged into the target CDB at the time the script is invoked and the virtual PDB will be in the mounted (not open) state. The PDB conversion script should return with the virtual PDB in either the mounted or open (not restricted) state. Delphix does not enforce a time-out for the script.

```
#!/bin/sh
```

```

DELPHIX_PDB_NAME=$1
SCRIPT_DIR="$( cd "$( dirname "$0" )" && pwd )"
CONVERT_LOGFILE=$SCRIPT_DIR/$DELPHIX_PDB_NAME-pdbconvert.log

sqlplus "/ AS SYSDBA" <<-EOF
  whenever sqlerror exit 2;
  spool $CONVERT_LOGFILE replace
  alter session set container=$DELPHIX_PDB_NAME;
  @?/rdbms/admin/noncdb_to_pdb.sql
  exit;
EOF

```

### PDB upgrade and conversion script

This script upgrades the newly provisioned vPDB to the target CDB version and then converts the source/Golden VDB datafiles into PDB datafiles. The script should be named `dx-post-plug-hook.sh` and reside in the root of the Delphix toolkit directory of the Linked CDB target host. Delphix will supply the name of the PDB being provisioned/converted as the first parameter. The VDB datafiles will have already been plugged into the target CDB at the time the script is invoked and the virtual PDB will be in the mounted (not open) state. The PDB conversion script should return with the virtual PDB in either the mounted or open (not restricted) state. Delphix does not enforce a time-out for the script.

```

#!/bin/sh

DELPHIX_PDB_NAME=$1
SCRIPT_DIR="$( cd "$( dirname "$0" )" && pwd )"
UPGRADE_LOGFILE=$SCRIPT_DIR/$DELPHIX_PDB_NAME-dx-post-plug-upgrade.log
UPGRADE_LOGDIR=$SCRIPT_DIR/$DELPHIX_PDB_NAME-upgrade

mkdir $UPGRADE_LOGDIR
cd $ORACLE_HOME/rdbms/admin
switches="-c '$DELPHIX_PDB_NAME' -l $UPGRADE_LOGDIR"
$ORACLE_HOME/perl/bin/perl catctl.pl $switches catupgrd.sql &>> $UPGRADE_LOGFILE

CONVERT_LOGFILE=$SCRIPT_DIR/$DELPHIX_PDB_NAME-pdbconvert.log

sqlplus "/ AS SYSDBA" <<-EOF
  whenever sqlerror exit 2;
  spool $CONVERT_LOGFILE replace
  alter session set container=$DELPHIX_PDB_NAME;
  @?/rdbms/admin/noncdb_to_pdb.sql
  exit;
EOF

```

## Provisioning a VDB from an encrypted Oracle database

### Overview

This topic describes how to provision a VDB from an encrypted database. The Delphix Engine supports provisioning from a dSource linked to a physical database that has been encrypted with Oracle's Transparent Database Encryption (TDE), which can be used to encrypt columns or tablespaces.

**[-]** The Delphix engine does not support provisioning from a dSource with an encrypted system tablespace in a non-multitenant configuration.

Provisioning a VDB from an encrypted dSource requires an auto-open wallet setup in the target environment, because the provisioning process requires the master key to be stored in the wallet file. On the dSource, export the keys and copy the export file (both `ewallet.p12` and `cwallet.sso`) to the VDB server. On the VDB server, create an empty wallet and import the keys into the wallet, then set the key to be used.

When provisioning a VDB from an encrypted dSource, if the target environment has other databases that also use TDE, each database should use a different wallet. This also includes a scenario where the VDB has been provisioned back to the same environment as the encrypted dSource. Please check Oracle documentation on how to set up different wallet locations for different databases. For example, use `$ORACLE_SID` in the `DIRECTORY` clause of the `ENCRYPTION_WALLET_LOCATION` parameter in `sqlnet.ora`.

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/opt/oracle/wallets/$ORACLE_SID)))
```

### Procedure

1. Check for any encrypted columns or tablespaces on the source database by using these commands:

```
SELECT t.name name, e.encryptionalg algorithm FROM v$tablespace t,
v$encrypted_tablespaces e
WHERE t.ts# = e.ts# and upper(e.encryptedts) = 'YES';
```

2. Copy wallet files from the source database to the target environment, and then configure the `sqlnet.ora` file on the target to point to the directory where the wallet is located.

```
$ more sqlnet.ora
ENCRYPTION_WALLET_LOCATION=(SOURCE(METHOD=file) (METHOD_DATA=(DIRECTORY=/opt/oracle/oradata/nf/wallet)))
```

3. If the source database does not use the auto-open wallet, create the auto-open wallet at the target environment.

```
$ orapki wallet create -wallet /opt/oracle/oradata/nf/wallet -auto_login [-pwd password]
```

4. Proceed with provisioning the VDB as described in [Provisioning an Oracle VDB](#)

## Managing multiple virtual PDBs in a virtual CDB

### Overview

Earlier, only one virtual PDB was supported in a virtual CDB. Starting with Delphix Engine version 8.0.0.0, you can provision multiple vPDBs in a vCDB. This enables you to manage vCDBs and vPDBs independently, when there are more than one vPDB in a vCDB.

This new feature is supported for Oracle versions 12.1.0.2 and later only.

- = To support multiple vPDBs in a vCDB, Oracle 12.1.0.2 needs an Oracle patch for bug 18967466. Once the patch or update (containing the patch) is installed, make sure that the `appliedPatches` property of the Oracle repository is also updated to include the bug number. Refer to [Updating repository for applied patches with the Command Line Interface](#) for instructions.

### Managing vCDBs

You can enable/disable, start/stop or delete a vCDB using **Actions (...)** menu from the **Delphix Management** application.

#### Prerequisites

- To disable a vCDB, all of its vPDBs must already be disabled using Delphix Management application.
- To stop a vCDB, all of its vPDBs must already be stopped or disabled using Delphix Management application.
- To delete a vCDB, all of its vPDBs must already be deleted using Delphix Management application.

#### Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Select the vCDB you want to manage.
4. Click **Actions (...)** menu
5. Select the desired action for the vCDB.

### Managing vPDBs

You can refresh/rewind(undo refresh), enable/disable, start/stop or delete a vPDB using **Actions (...)** menu from the **Delphix Management** application.

#### Prerequisites

- To disable a vPDB, its vCDB must be in a running state. You cannot disable a vPDB if its vCDB is in a stopped/disabled state. This is required in the current Delphix Engine version, because in previous versions disable succeeds even if the vCDB is in a stopped/disabled state.
- To enable/start a vPDB, if there are multiple vPDBs in its vCDB, then vCDB must have been enabled/started and open in RW mode already. If the vCDB is not enabled/started, enable/start it using **Delphix Management** application's **Action (...)** menu as mentioned in above.

#### Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.

3. Select the vPDB you want to manage.
4. Click **Actions (...)**
5. Select the desired action for the vPDB.

Make sure to follow the below points, once the desired action is selected.

- Refresh/Rewind:
  - Only one vPDB in a vCDB with source-level parent-child relationship: Both the vPDB and its vCDB will be refreshed/rewound.
 

**Note** : The vPDB and its vCDB has a source-level parent-child relationship if the dSource CDB timeflow, from which vCDB timeflow is derived, is the same as the parent CDB timeflow of the dSource PDB timeflow from which vPDB is derived. This was always the case when there was only one vPDB in a vCDB. But with multiple vPDBs support, this may not be always the case, since later vPDB (provisioned to the same vCDB) may be provisioned from a dSource PDB of a different dSource CDB.

Consider the following scenarios:

    - i. Provisioning a vPDB (VPDB1) from a dSource PDB (PDB1 in a source CDB1) to a new vCDB (VCDB1) will create a vPDB-vCDB virtual databases with source-level parent-child relationship. If such a vPDB is refreshed/rewound, then both vPDB and its vCDB will be refreshed/rewound.
    - ii. Provisioning a 2nd vPDB (VPDB2) from another dSource PDB (PDB2 in another source container CDB2) to the same vCDB (VCDB1) will create vPDB-vCDB databases (i.e. VPDB2-VCDB1) that does not have such a relationship. So, if such a vPDB is the only vPDB in the vCDB, then only the vPDB will be refreshed/rewound and not its vCDB.
  - Only one vPDB in a vCDB with no source-level parent-child relationship: Only the vPDB, on which the action is performed, will be refreshed/rewound. Its vCDB will not be refreshed/rewound. (Refer to the example scenario 2 above.)
  - Multiple vPDBs in a vCDB: Only the vPDB, on which the action is performed, will be refreshed/rewound.
- Disable/Stop:
  - If there are multiple vPDBs in a vCDB, then the action will be performed only for the vPDB.
  - If there is only one vPDB in the vCDB, then its vCDB will be also be disabled/stopped after the vPDB is disabled/stopped.
 

**Note** : This differs from the previous Delphix Engine(version above 8.0.0.0) behavior which always disabled/stopped the vCDB as well.
- Enable/start:
  - If there are multiple vPDBs in a vCDB, then the action will enable/start the vPDB only.
  - If there is only one vPDB in the vCDB, then the vCDB will be also be enabled/started if required before enabling/starting the vPDB itself.
- Delete
  - If this is the last vPDB in a vCDB, then the vCDB is also deleted.
  - If you are deleting a vPDB using the force option, make sure to follow the steps below to clean up the vPDB from the target host:
    1. Drop the virtual PDB from the virtual CDB manually after it is deleted from the Delphix Management UI.
    2. Remove the virtual PDB mount point from the target host (residing in the mount base directory) to avoid stale mounts.

 If a physical PDB is added to a virtual CDB or a virtual PDB from a virtual CDB is deleted using the force option, LogSync will fail with the error "Virtual container database <vCDB Name> has pluggable databases that are not managed by Delphix: <PDB names>." and/or

SnapSync will fail with the error code

"`exception.oracle.vdb.foreign.pdbs.found.in.vcdb`". To resolve the errors, unplug the physical PDBs from the virtual CDB manually or drop the virtual PDBs (that were deleted from Delphix using the force option) from the virtual CDB manually.

### Refreshing and rewinding a TDE-enabled vPDB

Just like a non-TDE-enabled vPDB, a TDE-enabled vPDB can be refreshed from the dSource or rewound to a previous snapshot or point in time. In each case, no additional manual steps or input from the user is required. The first step of a refresh or rewind operation is to disable the existing vPDB, which will result in a new keyfile exported to the artifact directory. The appropriate snapshot files are then mounted for the auxiliary database so that it can be recovered and brought to a consistent state. Since the vPDB is TDE-enabled, a keystore is needed for the recover operation. For a refresh, the Delphix Engine will use the parent keystore, and for a rewind, the Delphix Engine will use the target keystore, as shown below.

### Key rotation

There are two potential places for keys to be rotated in a vPDB environment:

1. **dSource:** If the dSource keys are rotated and a new snapshot taken with the new key, the customer is responsible for updating the parent keystore before refreshing from the later snapshot encrypted with the new key. The parent keystore would then contain both the new key and the original keys.
2. **Target:** If the target CDB keys are rotated, the target keystore will be updated. This is why the Delphix Engine uses the target keystore for rewind operations.

In either scenario, the keystore used for recovery will contain the current and all prior keys used to encrypt the datafiles and archive logs, for both the vPDB and CDB used in the auxiliary container.

### vPDB encryption key management

During the provisioning process of a TDE-enabled vPDB, Delphix generates a unique encryption key for the vPDB. This unique key is not associated with the parent keystore to ensure that no keys from the parent are imported by the target. During refresh and rewind operations, Delphix reuses that key after recovery has finished. It is possible to customize the key that is used by updating the `tdeKeyIdentifier` parameter of the source via the CLI. If a valid `key_id` is entered for a key that is already present in the keystore, that key will be used as the active encryption

key for the vPDB at the end of refresh/rewind. If the field is unset, Delphix will generate a new encryption key for the vPDB to be used from that point onward. This procedure is the same when using a vCDB, in which case Delphix will also generate a new unique encryption key for the vCDB that is reused for refresh and rewind, and which can be customized by updating the `tdeKeyIdentifier` parameter of the CDB source. See the CLI steps for [Locating and Updating the Value of tdeEncryptionKey](#)

## Timeflows for RAC provisioning of VDBs

### Overview

This topic describes special considerations when provisioning by timestamp from a RAC time flow.

Timestamps in Oracle RAC time flows can be imprecise because of time skew among the hosts in a RAC configuration. The time stamps will generally track the host with the fastest clock. For this reason, provisioning by a timestamp may not leave the VDB provisioned at the exact time desired. The provision by SCN should be used if more fine-grained control is required when provisioning.

### Introduction

The Delphix Engine provides the ability to link to an external database by creating a dSource within the Delphix system. Once linked, the Delphix Engine maintains a complete history of the database as part of a Timeflow, limited by the retention policies configured by the administrator. From any time within that Timeflow, you can provision a virtual database (VDB) from the Delphix Engine. This Timeflow is maintained through the use of SnapSync and LogSync.

The SnapSync operation pulls over the complete data set of the external database during the initial load. Subsequent SnapSync operations pull and store only incremental changes. At the end of each SnapSync operation, the Delphix Engine creates a snapshot that serves as the base point for provisioning operations. In addition, LogSync periodically connects to the host(s) running the source database and pulls over any log files associated with the database. These log files are stored separately from the SnapSync data and are used to provision from points in between SnapSync snapshots. Usually, SnapSync operates against a live database with changes actively being made to it. Hence the data that it pulls over is “fuzzy” and logs must be applied to the data to make it consistent and provisionable. If LogSync is enabled, SnapSync relies on it to copy the logs over. If LogSync is not enabled, SnapSync copies the logs itself. Occasionally, LogSync or SnapSync is not able to retrieve one or more log files from the database. This creates a break in the Timeflow or can prevent a snapshot from being provisioned. To remedy this situation, the Delphix Engine has tools to repair, or patch, a snapshot and the Timeflow.

### Snapshot repair

#### ASM

The steps below do not apply if your archive logs are stored on ASM. If they are stored on ASM, you must move the archived logs to a supported filesystem directory.

When missing log files prevent the Delphix Engine from provisioning a snapshot, you can use the Delphix Management application to identify the missing logs and repair the snapshot. The Delphix Engine will generate a fault whenever missing logs prevent a snapshot from being provisionable. The fault will likely have the title "Cannot provision database from snapshot" and will contain a description of the cause. The common causes are:

- Logs were deleted/moved/archived from the database before the Delphix Engine could retrieve them. In this case, the archive log retention policy on the source database may be too aggressive. Use the GUI snapshot repair tool to fetch the logs.
- LogSync is still fetching the logs. SnapSync is relying on LogSync to fetch the logs needed to make the snapshot consistent. SnapSync normally will wait up to 15 minutes for LogSync to fetch the logs. If LogSync has not fetched the logs by then, SnapSync will generate a fault and finish. The best course of action, in this case, maybe to wait for LogSync to fetch the logs.
- The source database is a physical standby in real-time apply mode. The changes described in the current online log of the database are needed to make the snapshot consistent. LogSync cannot retrieve the log until it is archived, and SnapSync cannot force the log to be archived because the source database is a physical standby. Force a log switch on the primary database or wait until the log is naturally archived.

Below is a screenshot of a snapshot with missing logs. Clicking on the snapshot causes the list of missing log(s) to appear. In this example, log sequence 404 is missing.

Snapshot with missing logs

If the snapshot can be repaired by fetching the logs from the source database, then you can use the GUI snapshot repair tool to fetch the logs. Hovering over the snapshot exposes more options ("...") which can then be clicked to show the **Repair Missing Archive Logs** option. Clicking on the option starts the repair tool.

Selecting the repair tool

Repair tool

To use the snapshot repair tool, as seen above:

1. Enter a **Hostname**. This should be the host from which to retrieve the log(s).
2. Enter a **Username** and **Password**. These should be the credentials for a user who can read the archived log file(s). The user credentials are optional if the host and user credentials have already been added to the Delphix Engine.
3. Enter a **File Path**. This should be the name of the directory containing the missing log(s).

If more than one file is missing, they should all exist in the directory specified by **File Path**. The tool will read every file in the **File Path** directory, so it is best that it only contains the files that are to be retrieved.

### Timeflow patching

When missing log files cause a break in the Timeflow, you can use the command-line interface (CLI) to identify the missing logs and patch the Timeflow. The Delphix Engine will generate a fault whenever there are missing logs on a portion of the Timeflow. The fault will likely have the title “Cannot provision a database from a portion of Timeflow” and will contain a description of the cause. The most common cause is an overly aggressive archive log retention policy on the source database causing a log to be deleted before LogSync can fetch it. Other faults can also be generated by describing the specific errors encountered when fetching the log(s).

You can use the CLI to list the missing logs and patch the Timeflow. The following CLI Cookbook entry demonstrates how to do this: [CLI Cookbook: Repairing a Timeflow](#)

If you delete or move archive logs from the source database that are not needed for a snapshot, you still may need to repair the TimeFlow to provision using LogSync. In this case, an icon will not be visible on the TimeFlow tabs. This means you cannot repair the TimeFlow in the GUI. However, you can still repair it using the CLI.

## Upgrading an Oracle VDB, linked CDB, or a vCDB

### Prerequisites

Upgrading a VDB involves Oracle level activity and Delphix GUI/CLI level activity. The Oracle activity, to be performed first, involves upgrading/patching current oracle homes, installing new oracle homes, and managing init.ora/spfile.ora files. The Delphix GUI/CLI activity, to be performed second, involves rediscovering new oracle installations, giving a VDB a new oracle home, and updating the oracle grid home. These are discussed in detail below.

-  During an Oracle upgrade, refreshing an Environment will generally discover new Oracle installations, allowing for a virtual database (VDB) or dSource upgrade to be handled through the UI. However, if the Oracle Grid home was changed, due to an Oracle upgrade, the crsClusterHome parameter will need to be updated manually through the command line (CLI).

### Limitations

Currently, it is not possible to convert an existing VDB into a vPDB.

### PSU/Oracle upgrade procedure

Normally a PSU or Oracle upgrade will have both binary changes and some scripts to run on the database side as well.

There are 3 ways to apply a PSU/Oracle upgrade:

1. Apply to existing ORACLE\_HOME. You must be on Delphix version 4.1.x or higher to do this.
2. Create a new ORACLE\_HOME (could clone the existing one) and then apply the PSU to the new ORACLE\_HOME
3. After a dSource is upgraded, use refresh on the Timeflow tab to upgrade the VDB

Follow Oracle documentation and run the appropriate script(s) and/or steps on the databases using those ORACLE\_HOMES. In option B, stop the instance using the old ORACLE\_HOME, then restart the instance with the new ORACLE\_HOME from the command line as normal.

### Applying to an existing ORACLE\_HOME

1. Following Oracle documentation, patch the ORACLE\_HOME, then the database for the VDB(s).
2. Refresh the environment the VDBs are on in the Delphix Management application.

### Creating a new ORACLE\_HOME

1. Refresh the environment from the Delphix Management application. Verify that the new ORACLE\_HOME is picked up and displayed in the **Databases** tab as an ORACLE Installation.
2. Stop the VDB instance (old ORACLE\_HOME) using Oracle tools. Do not use the Delphix VDB **stop** operation as the VDB should be stopped outside of Delphix.
3. Export ORACLE\_HOME=(newORACLE\_HOME). Follow Oracle documentation to patch the database.
4. Copy the init.ora for that VDB in this new \$ORACLE\_HOME/dbs directory. The delphix\_os user will need the write permissions to this directory.
5. If there are any database parameter changes, update the spfile located on the Delphix mount base with those values.
6. Navigate to the **Datasets** view
7. Expand the group(s) containing all non-multitenant and multitenant VDBs.
8. Click the **Configuration** tab.

9. From the Actions menu (...) select **Upgrade** to switch the ORACLE\_INSTALLATION to the new one.
10. If the database is a linked CDB or vCDB, go to any child vPDBs and verify that the **Repository** and/or **Version** has been updated under the **configuration** tab.

#### Using refresh

1. Refresh the environment from the Delphix Management application.
2. Verify that the new ORACLE\_HOME is picked up and displayed in the **Databases** tab of the **Environments** screen as an ORACLE Installation.
3. On the **VDB Configuration tab**, click the **stop** icon to stop the VDB.
4. From the Actions menu (...) select **upgrade** to switch the ORACLE\_INSTALLATION to the new upgrade version same as the dSource.
5. Navigate to the **Datasets** view, select the VDB, and then select the **Timeflow** tab.
6. Click the **Refresh** button.
7. Select a new **snapshot** from the dSource that was taken after the dSource was upgraded. (The database version is on the snapshot card.)

#### **Updating the Oracle user after an upgrade**

There may be cases when you upgrade the Oracle home and the Oracle User (who owns the binary) is a different user than the previous Oracle User. You will then need to update the Oracle User for each environment, and then re-connect each VDB to the upgraded Oracle home using the new Oracle User. The new Oracle User must be in the same OS group (for example, dba or oinstall) as the previous one.

1. Login to the Delphix Management application using delphix\_admin credentials.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **environment** where you want to add the user.
5. Next to **Environment Users**, click the **Pencil** icon to add the new user.
6. Set the new user as the **default** user.
7. Follow the procedure to upgrade VDBs described in this topic.

#### Linked CDB upgrade procedure

For vPDBs in the linked CDBs, there are two ways to upgrade the linked CDB:

- A. Perform the Oracle upgrade of the current target CDB.
- B. Create an entirely new target CDB of the higher version.

#### Performing the Oracle upgrade of the current target CDB

1. Perform the Oracle upgrade of the current target CDB.
2. Login to the Delphix Management application.
3. Navigate to **Manage > Datasets** and select the target CDB.
4. From the **Actions** menu (...), select **Upgrade** to switch the ORACLE\_INSTALLATION to the new one.
5. Click Upgrade.
6. Under the **Configuration** tab, verify that the **Repository** and/or **Version** has been updated.

#### Creating a new target CDB

You can first disable the vPDB, then use the migrate vPDB feature to select a new container database.

#### Procedure

1. Login to the Delphix Management application.
2. Navigate to **Manage > Datasets**.

3. Select the vPDB you want to migrate.
4. From the **Actions** menu (...) select **Disable**.
5. Click **Disable** to confirm.
6. From the **Actions** menu (...) select **Migrate**.
7. Select the new container database for the vPDB, the user for that environment, and the database installation where the container database of the vPDB will reside.
8. Click the **Migrate** option to confirm your selections.
9. Manually copy the exported keys to the target host's toolkit directory.
10. From the **Actions** menu (...) select **Enable**.
11. Click **Enable** to confirm. Your vPDB will re-start in the new environment, and you can continue to work with it as you would any other vPDB.

## Customizing RAC instances after provision

Provisioning a RAC VDB requires users to select which RAC node to be included for this VDB, as well as the instance number and instance name of each RAC node that runs the RAC VDB. At any time after the provision, there may be a need to downsize or increase the number of instances of the RAC VDB or reassign instance number and instance names to individual VDB RAC node.

### Oracle pluggable database

The current release does not support the customization of RAC vPDB instances after provision.

If you make any changes to the VDB's configuration on the engine either by changing the VDB's configParams using CLI or VDB configuration template that was used to provision it, the Delphix engine will push out these changes when the VDB is next enabled after the RAC instance changes are made.

### Procedure

The following steps illustrate how you can customize your RAC VDB instance configuration after provision:

1. Login to your Delphix Management application.
2. Select the VDB you want to edit.
3. From the right-side pane select the **Configuration** tab.
4. From the Action menu (...), select **Disable**.

5. Click on the **pencil** icon next to 'CLUSTER INSTANCES' to be able to edit your instance names.
6. Click on the name of the instance you want to alter and edit it to suit.

7. Check or uncheck the check-box to the left to indicate if you want to add or remove a cluster node for your RAC VDB.
8. Complete editing and then confirm using the tick icon.
9. From the Action menu (...), select **Enable**.

**i** Disabling a VDB will result in the VDB Instances being shut down and the NFS mounts for that VDB presented from Delphix being dismounted.

## Migrating an Oracle VDB

This topic describes how to migrate a Virtual Database (VDB) from one target environment to another.

There may be situations in which you want to migrate a virtual database to a new target environment, for example when upgrading the host on which the VDB resides, or as part of a general data center migration. This is easily accomplished by first disabling the database, then using the Migrate VDB feature to select a new target environment.

### Prerequisites

- You should have already set up a new target environment that is compatible with the VDB that you want to migrate.
- You cannot migrate a single instance of Oracle VDB to a RAC environment and vice versa. An additional reconfiguration is needed when converting a single instance to RAC that is only performed during a VDB provision. Instead, you should provision a new VDB.

### Procedure

1. Login to your Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **VDB** you want to migrate.
5. From the Actions menu (...) select **Disable**.
6. Click **Disable** to confirm. When the VDB is disabled, its icon will turn grey.
7. From the Actions menu (...) select **Migrate**.
8. Select the new target environment for the VDB, the user for that environment, and the database installation where the VDB will reside.

## Migrate

### Current Environment

<b>Database</b> dbdh_6U8	<b>Environment</b> Starfire
<b>Installation</b> /u01/app/ora10205/product/10.2.0/db_1	<b>User</b> ora10205

### New Environment

#### Environment

#### User

#### Installation

If the new installation is not in the current list, you can try to discover it by refreshing the environment. If the new installation is not discovered automatically, you can add it manually.

9. Select **Migrate** to confirm your selections.
10. From the Actions menu (...) select the **Enable**
11. Click **Enable** to confirm.

Within a few minutes, your VDB will re-start in the new environment, and you can continue to work with it as you would any other VDB.

## Migrating a vPDB

There may be situations in which you want to migrate a virtual pluggable database (vPDB) to a new container database on the same or a different target environment, for example when upgrading the host on which the vPDB resides, or as part of a general data center migration. This is easily accomplished by first disabling the vPDB, then using the Migrate vPDB feature to select a new container database.

 The current release only supports migrating from a vPDB in a virtual CDB, to another linked or virtual CDB using the CLI.

### Pre-requisites

- You should already set up and have Delphix discover a container database in the same environment as the vPDB currently is or from an environment to which the vPDB will be migrated to.
- The virtual CDB from/to which vPDB is to be migrated must be already running and open in a read-write mode.

### Procedure

Login to your Delphix Management application.

1. Click **Manage**.
2. Select **Datasets**.
3. Select the **vPDB** you want to migrate.
4. From the Actions menu (...) select **Disable**.
5. Click **Disable** to confirm.
6. From the Actions menu (...) select **Migrate**.
7. Select the new **container database** for the vPDB, the **user** for that environment, and the **database installation** where the container database of the vPDB will reside.
8. Click the **Migrate** to confirm your selections.
9. Manually copy the exported keys to the target hosts toolkit directory. When migrating a TDE enabled vPDB, the disable step results in the vPDB keys being exported to the toolkit. Enabling the vPDB in a different target host will result in plugin violations, therefore when migrating to a new host, the user must manually copy the exported keys to the toolkit directory on the target host.
10. From the Actions menu (...) select **Enable**.
11. Click **Enable** to confirm. Your vPDB will re-start in the new environment, and you can continue to work with it as you would any other vPDB.

### Migrating a TDE-enabled vPDB

Migrating a vPDB from one container database to another involves the following steps:

1. Disable the vPDB.
2. Migrate.
3. For a TDE-enabled vPDB, there are additional steps that are required before the enable. The steps are necessary because the keystore and exported keyfiles are not present on Delphix storage. These steps are:
  - a. Move the parent TDE keystore from the original target host to the new host. If the vPDB is not being migrated to a new host, then this step is not needed. Similarly, if the new host has the parent keystore in a different location, then the parent keystore path for the vPDB needs to be updated.
  - b. Move the artifact directory for the vPDB from the original target host to the new host. If the vPDB is not being migrated to a new host, then this step is not needed.
  - c. Ensure that the new target container has the TDE keystore password set.
  - d. Merge the original target keystore into the new target keystore. This is required to support a rewind operation to a snapshot taken before the migrate.
4. Enable.

The diagram below illustrates the scenario of a migrated TDE-enabled vPDB.

#### Example

Consider the following TDE-enabled vPDB:

 **tde\_vpdb** 

Timeflow      Status      Configuration

---

Source      Policies      Masking      Hooks

---

**DATABASE** 

**Container Database**

**Name**

**Version**  
Oracle 18.3.0.0.0

**Size**  
0.00B

**Parent Database TDE Keystore Location**  
None

**User**  
oracle

**Custom Environment Variables**

**ENVIRONMENT** 

**Name**

**OS**  
Linux (CentOS)

**Timezone**  
America/New\_York,EDT-0400

**User**  
oracle

**Repository**  
/u01/app/oracle/product/18.0.0.0/dbhome\_1

---

No items

This vPDB is currently provisioned to the container database CDOMLOTG9620 on the host tde-target18. Connecting to that database, we can see the keys for the target container and the vPDB:

```
SQL> show pdbs
CON_ID  CON_NAME                OPEN MODE  RESTRICTED
-----  -
      2  PDB$SEED                READ ONLY  NO
      3  CDOMLOTG9620PDB1        READ WRITE NO
      4  CDOMLOTG9620PDB2        READ WRITE NO
      5  CDOMLOTG9620PDB3        READ WRITE NO
      6  TDE_VPDB                 READ WRITE YES
SQL> select con_id, key_id from v$encryption_keys;
CON_ID  KEY_ID
-----  -
      1  ASFwmcfaMk8vv1LvzV0H8BEAAAAAAAAAAAAAAAAAAAAAAAAAAAA
      6  AdDdKibLKU9mv6PDAIvVh0AAAAAAAAAAAAAAAAAAAAAAAAAAAA
```

The key for the target container starts with **ASFwmcfa** and the vPDB key starts with **AdDdKibL**. We also have an artifact directory for this vPDB found in `/work/oracle_tde_keystores`:

```
$ ls /work/oracle_tde_keystores/
tde_vpdb_Encrypted_e9d2befb-9849-43c8-85f5-5ee8b760e334
```

We are going to migrate this vPDB to the container database CDOMLOTGCAE8 located on the host tde-target18b. Currently, that container has the following configuration:

```
SQL> show pdbs
CON_ID  CON_NAME                OPEN MODE  RESTRICTED
-----  -
```

```

2 PDB$SEED          READ ONLY  NO
3 CDOMLOTGCAE8PDB1  READ WRITE NO
4 CDOMLOTGCAE8PDB2  READ WRITE NO
5 CDOMLOTGCAE8PDB3  READ WRITE NO
SQL> select con_id, key_id from v$encryption_keys order by con_id;
CON_ID KEY_ID
-----
1 Ad344VSUDk/jv1VDb1QNBHMAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
3 AetaL+IKpE+ov5avXouApwUAAAAAAAAAAAAAAAAAAAAAAAAAAAA
4 AXZTgaBbxk+6v6x2yHQ4ArgAAAAAAAAAAAAAAAAAAAAAAAAAAAA
5 AayTgbjkJE/3v82/hBBBAWEAAAAAAAAAAAAAAAAAAAAAAAAAAAA
    
```

The new target container has a CDB key starting with **Ad344VSU**. The migration steps are as follows:

1. Disable the vPDB in the original container.
2. Migrate the vPDB to point to the new container on the new host. The UI will report the following warnings during the migrate operation, which indicate the manual steps which need to be done:

3. Set the TDE keystore password for the new target container CDOMLOTGCAE8.
4. Move the parent keystore to the new target host tde-target18b. In this case, we will keep the existing location /u01/app/oracle/product/18.11.0.0/dbhome\_1/admin/CDOMSHSR52CA/wallet on both hosts, so the configuration does not need to be updated.
5. Move the TDE artifact directory /work/oracle\_tde\_keystores/tde\_vpdb\_Encrypted\_e9d2befb-9849-43c8-85f5-5ee8b760e334 to the new target host. If there are no TDE-enabled vPDBs on the new host, the oracle\_tde\_keystores directory may need to be created first.
6. Merge the original target keystore into the new target keystore. Oracle provides the ADMINISTER KEY MANAGEMENT MERGE KEYSTORE command to facilitate this. Note that you cannot successfully merge into a keystore that is currently in use by the database, so the recommended process is to first copy the original target keystore to the new host, merge the two keystores into a new keystore, replace the existing new target keystore and finally bounce the CDB to start using the merged keystore:
  - a. Copy the original keystore to /tmp/tde-target18a on tde-target18b
  - b. While connected to the new container, issue the merge keystore command:

```

SQL> administer key management merge keystore '/tmp/tde-target18a'
      identified by *** and keystore '/u01/app/oracle/product/18.11.0.0/
      dbhome_1/admin/CDOMLOTGCAE8/wallet' identified by *** into new keystore '/'
      tmp/merged' identified by ***;
    
```

- c. Copy the new merged keystore into the existing keystore location (backing up the existing keystore first).
  - d. If there is an autologin wallet configured for the container, it must be recreated.
  - e. Shutdown and restart the new target container database.
7. Confirm that the keystore now contains both the original key and the new key:

```
SQL> select key_id from v$encryption_keys where con_id = 1;
KEY_ID
-----
ASFwmcfaMk8vv1LvzV0H8BEAAAAAAAAAAAAAAAAAAAAAAAAAAAA
Ad344VSUDk/jv1VDb1QNBHMAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
```

Note that we have the key starting with **ASFwmcfa** from the original container, and the key starting with **Ad344VSU** from the new container.

8. Enable the vPDB to complete the migration operation. We can now see that the vPDB is successfully started in the new container, with its key starting with **AdDdKibL**:

```
SQL> show pdbs
CON_ID CON_NAME          OPEN MODE  RESTRICTED
-----
 2 PDB$SEED             READ ONLY NO
 3 CDOMLOTGCAE8PDB1    READ WRITE NO
 4 CDOMLOTGCAE8PDB2    READ WRITE NO
 5 CDOMLOTGCAE8PDB3    READ WRITE NO
 6 TDE_VPDB            READ WRITE NO
SQL> select con_id, key_id from v$encryption_keys order by con_id;
CON_ID KEY_ID
-----
 1 Ad344VSUDk/jv1VDb1QNBHMAAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 1 ASFwmcfaMk8vv1LvzV0H8BEAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 3 AetaL+IKpE+ov5avXouApwUAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 4 AXZTgaBbxk+6v6x2yHQ4ArgAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 5 AayTgbjkJE//v82/hBBBAWEAAAAAAAAAAAAAAAAAAAAAAAAAAAA
 6 AdDdKibLKU9mv6PDAlVvVh0AAAAAAAAAAAAAAAAAAAAAAAAAAAA
6 rows selected.
```

## Migrating a vPDB (from a linked CDB) to a higher Oracle version (linked CDB)

Given a vPDB in a linked CDB (CDBold for hereon) the following steps can be used to migrate it to a higher Oracle version linked CDB (CDBnew from hereon):

- It might be necessary to run pre-upgrade Oracle scripts before doing the upgrade, consult Oracle documentation.
- Disable the vPDB, using the GUI or the CLI.
- Using the CLI perform manual migration. If the CDBnew is in the same host as the CDBold, then only cdbConfig needs to be specified, otherwise the repository and the environmentUser also need to be specified:

```
> cd /sourceconfig
sourceconfig> select vpdb
sourceconfig 'vpdb'> update
sourceconfig 'vpdb' update *> set cdbConfig=CDBnew
sourceconfig 'vpdb' update *> set environmentUser=<new oracle user>'
sourceconfig 'vpdb' update *> set repository=''
sourceconfig 'vpdb' update *> commit
```

- After enabling the vPDB without starting, the environment of the linked CDB should not be refreshed until the vPDB has been created and upgraded.

- Enable the vPDB without starting it:

```
> cd /source
source> select vpdb
source 'vpdb'> enable
source 'vpdb' enable *> set attemptStart=false
source 'vpdb' enable *> commit
```

- Add the vPDB to CDBnew using sqlplus, which has two options:
  - The vPDB can be plugged as a clone (to get a new DBID/GUID):

```
SQL> create pluggable database vpdb as clone using'/mnt/provision/vpdb-
CDOMLOSRA92E/datafile/delphix_group_writable/VPDB.xml' nocopy tempfile
reuse;
```

- The vPDB can be plugged without the clone option (to retain the same DBID/GUID):

```
SQL> create pluggable database vpdb using'/mnt/provision/vpdb-
CDOMLOSRA92E/datafile/delphix_group_writable/VPDB.xml' nocopy tempfile
reuse;
```

- Open the vPDB in upgrade mode:

```
SQL> alter pluggable database vpdb open upgrade;
```

- Upgrade the vPDB following the procedures documented by Oracle.
- Take a new snapshot with the new version upgraded and delete the previous snapshot containing the previous version metadata.

All Delphix operations on the upgraded vPDB are possible, which include:

- Start
- Stop
- Enable
- Disable
- Taking a snapshot
- Rewind (to an upgraded snapshot)
- Refresh (requires additional steps)
  - Disable the vPDB
  - Using the CLI to migrate the vPDB back to CDBold:

```
> cd /sourceconfig
sourceconfig> select vpdb
sourceconfig 'vpdb'> update
sourceconfig 'vpdb' update *> set cdbConfig=CDBold
sourceconfig 'vpdb' update *> set environmentUser=<old oracleuser>'
sourceconfig 'vpdb' update *> set repository=''
sourceconfig 'vpdb' update *> commit
```

- Refresh the vPDB
- Repeat the procedure for migration as described before

## V2P with an Oracle VDB

This topic describes the procedure for exporting a virtual database (VDB) to a physical one, also known as V2P.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets**.
3. Select the dSource or VDB you want to export.
4. Select the snapshot of the dSource or VDB state you want to export.
5. If you want to export the state of the database from a specific point in time, select the LogSync icon and then select the point in time from which you want to create the export.

6. From the actions menu (...) select **Virtual to Physical**.
7. Select the **target environment**. The target environment should have been added to Delphix previously and should meet all target host requirements, see [Requirements for Oracle hosts and databases](#)
8. Enter the Target Directory for the export.  
The target directory you enter must exist in the target environment, and the Delphix operating system user listed under the environment must have permission to write to it. The target directory should be empty.
9. Select whether or not to **Open database after recovery**.  
If you do not select this option, the Oracle database will not undergo open resetlogs, and the database will not be available for read/write access. This can be useful if the files are to be used to restore an existing data file for recovery purposes. You can use the scripts that are created in the target environment to complete the database open process at a later time. For more information, see [Manually recovering a database after V2P](#)
10. Click **Advanced** to customize **data transfer settings**, customize the **target directory layout**, enter any **database configuration** parameters or enter **file mappings** from the source environment to the target. For more information, see [Customizing target directory structure for database export](#), [Configuration settings for Oracle virtual databases](#) and [Customizing VDB file mappings](#). The data transfer settings are described below:
  - a. **Compression** – Enable compression of data sent over the network. Default is **Off**.
  - b. **Encryption** – Enable encryption of data sent over the network. Default is **Off**.
  - c. **Bandwidth Limit** – Select the network bandwidth limit in units of megabytes per second (MB/s) between the Delphix Engine and the target environment. The default is **0**, which means no bandwidth limit is enforced.
  - d. **Number of Connections** – Select the number of transmission control protocol (TCP) connections to use between the Delphix Engine and the target environment. Multiple connections may improve network throughput, especially over long-latency and highly-congested networks. The default is **1**.
  - e. **Number of Files to Stream Concurrently** – Select the number of files that V2P should stream concurrently from the Delphix Engine to the target environment. The default is **3**.
11. Click **Next**.
12. Select whether you want to have an email sent to you when the export process completes.
13. Click **Submit**.

### Post-requisites

If you did not select **Open Database After Recovery**, follow the instructions in [Manually Recovering a Database after V2P](#) to complete the database open process.

### Resumable V2P

Resumable V2P is a capability that allows you to suspend a V2P operation and then resume it at a later time, without redoing any of the work already completed. For example, any portion of a file that has already been

transferred to the target environment is not re-sent. For an entire file that has already been transferred, no part is re-sent.

The image below presents a progress bar, a stop button, and a pause button while a V2P is running. To manually suspend a V2P operation:

1. Click the pause button.

The next image represents a message alert generated after a V2P job has been suspended. To manually resume the job:

1. Click the play button.

The below image indicates that you can also pause and resume the initial snapsync from the **Actions** panel.

1. Click the resume button

### Recoverable errors

Broadly speaking, a "recoverable error" is an error condition caused by a disruption in the environment or on the target host, not errors in the actual V2P operation. Examples of recoverable errors include:

- A timeout due to a network outage
- Running out of disk space on the target environment
- An inability to create directories or files on the target environment

You can often address recoverable errors by taking some action to fix the problem, such as freeing up space on the target environment.

### Auto-suspend

A V2P operation that encounters a recoverable error is auto-suspended: it appears as a suspended job in the user interface (UI), with a message detailing the error condition. Once you have fixed the error, you can simply resume the job. Alternatively, you can cancel the job. Just as when you manually suspend and resume a job, any portion of a file that has been transferred, including possibly the entire file itself, is not re-sent when the job resumes.

## Export an Oracle VDB or a vPDB to a physical ASM or exadata database

### Overview

This article describes how to perform an export or an in-place conversion of a virtual database (VDB) or a virtual pluggable database (vPDB) into a physical database stored on Oracle Automatic Storage Management (ASM) disk groups. No intermediate storage is needed; the database files are moved directly from Delphix into the ASM diskgroup(s).

This procedure can be used to export an Oracle VDB, or a vPDB in a Linked CDB, to ASM disk group(s), including disk group(s) residing in an Oracle Exadata machine. The procedure follows Oracle's recommended best practice of using a single disk group for data files. A separate disk group can be specified for redo log files.

**i** This procedure can be performed using the CLI only and applies to all Oracle RDBMS Versions supported by Delphix; in addition, it is also fully supported with TDE-enabled virtual databases provisioned through Delphix.

### Prerequisites

1. Oracle Managed Files (OMF) must be enabled on the VDB or vPDB before export can be performed. OMF eliminates the need for the DBA to directly manage the operating system files that comprise an Oracle Database. As a result of this OMF requirement, it is expected that all database file names of the exported physical database would change.
2. The following conditions must be met prior to the export operation. Export will fail if any of these conditions are not met:
  - a. Sufficient storage space must be available in the target ASM diskgroup for datafiles and the target ASM diskgroup for online logs if specified. The validation of the target ASM diskgroup for online logs is only applicable in the case of VDBs and not vPDBs.
  - b. While exporting a vPDB, if a new PDB name is specified:
    - i. it must meet all the naming constraints as defined in the Oracle documentation.
    - ii. it must be different from the existing PDBs in the target CDB.
  - c. While exporting a VDB, if a new database unique name is specified:
    - i. it must meet all the naming constraints as defined in the Oracle documentation.
    - ii. it must be different from the database unique name of any other database on the same host.
    - iii. it must be different from the database unique name of any RAC database which has a node on this host even if the node is down.
  - d. No offline datafiles or tablespaces must exist in the VDB or vPDB.
  - e. The VDB or vPDB on which the export is initiated must be Open.
  - f. Export of a VDB in a RAC environment must be performed as the Oracle user, otherwise the export will fail. This is required because Delphix issues srvctl commands to configure the resulting physical database in RAC and these commands can only be run with Oracle user privileges.
  - g. No other job must be running on the virtual database or its associated environment.
  - h. When running export of a VDB or vPDB in a RAC environment, ensure that the states of all the cluster nodes are displayed as 'Enabled' in the Delphix management GUI. If one of the cluster nodes is disabled, the export operation will fail, although the physical copy has been completed and it is usable, however the VDB or vPDB will need to be force disabled manually.
3. If you want to export a vPDB in a vCDB, the vPDB must be migrated to a Linked CDB and then enabled, or alternatively, provision a child vPDB from this vPDB snapshot to a linked CDB and then perform the export.

### Procedure

1. Delphix takes a new snapshot of the virtual database/pluggable database before starting export. Also, Delphix retains the timeflow and all its snapshots after the virtual source is exported. As such, after export, the virtual source can be easily migrated and rewinded to the previously created snapshots.
2. It is recommended that the export be performed on a newly provisioned VDB or vPDB, although it can still be performed on your existing VDB or vPDB. The reason is it simplifies the post export process to re-enable the existing VDB or vPDB.
3. Please refer to the appropriate CLI cookbook sections for the procedure to export a VDB or export a vPDB to a physical ASM or Exadata database.

#### Performance considerations before running the export

1. When deciding the number of RMAN channels to use, there are tradeoffs between speed and resource consumption on the host.
2. The number of RMAN channels should not be more than the number of datafiles.
3. Similar to selecting the number of RMAN channels to perform backup, if impact to other databases is not a concern, then setting the number of channels should be increased to the point of diminished returns. Otherwise it is a compromise between what the system can handle and how fast we want the export to finish.
4. By default it is set to 8, but this value might be too large for some environments and should be adjusted down appropriately.

#### Considerations after successful export of a VDB or vPDB to ASM

After the export is successful, no Delphix operations are allowed on the VDB/vPDB except migrate or a fresh provision of a new child VDB or vPDB. However, there may be situations where you may need to re-enable the VDB or vPDB, please perform a migrate of the VDB/vPDB to a different host and/or CDB and then rewind the VDB/vPDB to its latest snapshot

1. After successfully performing export of a VDB to replace a linked physical database that is damaged and is unusable with new physical database having the same name, same unique name and same SID as the original damaged database, the new physical database can be linked back to Delphix engine using the following steps:
  - a. Delete or Migrate the VDB that was used to create a new physical database to a different environment.
  - b. Refresh the environment where the new physical database is created.
  - c. Detach the dSource from the original source database.
  - d. Force attach the dSource to the newly created physical database.
2. After successfully performing export of a vPDB with the new physical PDB name that is same as the vPDB name, the new physical PDB can be linked back to Delphix engine using the following steps:
  - a. Delete or migrate the vPDB to a different CDB.
  - b. Refresh the environment where the new physical PDB is created.
  - c. Detach the dSource PDB from the original source PDB.
  - d. Force attach the dSource to the newly created physical PDB.

## Move an Oracle VDB to a physical ASM or exadata database

### Deprecation Notice

**Warning:** This procedure is deprecated as of 9.0.0.0. Delphix recommends using the new export feature in 9.0.0.0 that is documented in the [Export an Oracle VDB or vPDB to a Physical ASM or Exadata Database](#) article. This procedure will be eventually removed in future versions of the Delphix Continuous Data Engine.

### Overview

This article describes how to move a virtual database (VDB) into a physical database stored on Oracle Automatic Storage Management (ASM) disk groups. This is a scripted procedure that is assisted (but not fully automated) by Delphix. No intermediate storage is needed; the database files are moved directly from Delphix into the ASM diskgroup(s).

This procedure can be used to export a VDB to ASM disk group(s), including disk group(s) residing in an Oracle Exadata machine. The `move-to-asm.sh` script follows Oracle's recommended best practice of using a single disk group for data files. A separate disk group can be specified for redo log files. Professional Services can be engaged if customization is needed.

 This procedure applies to **all** Oracle RDBMS Versions supported by Delphix; in addition, it is not supported by PDB/Multi-tenant type databases.

### Procedure

1. Create an ASM disk group that will contain all the database files. Optionally, create a separate disk group for redo log files.
2. Provision a VDB on the target machine that is running Oracle ASM or Exadata in order to do the export; this VDB will be deleted after the export is complete. This temporary VDB can be provisioned from an existing VDB. You can also provision it from a dSource, which allows you to achieve a full restore of the original source ASM database.
3. Login to the target machine (or a node of the target RAC cluster) where the VDB instance and ASM instance are running. The directory will be in the form:

```
<toolkit_path>/Delphix_<engine_id><user><host|cluster>/databases/oracle/  
<db_unique_name>/<database_sid>/
```

4. For a RAC database, be sure to use the directory path containing the SID of the instance running on the node where you have logged in.
5. Ensure that Oracle environment variables ORACLE\_HOME, ORACLE\_SID, and CRS\_HOME (RAC only) are correctly set for the VDB that needs to be moved.
6. Execute the script `move-to-asm.sh` as the **Environment User** who provisioned the single instance VDB. For a RAC VDB, the **Environment User** selected to execute the `move-to-asm.sh` *must* be the Oracle installation owner. This is due to an Oracle restriction that only the installation owner can invoke `srvctl` to add or remove database configurations. Alternatively, enter `move-to-asm.sh` as a **Post-Provision Hook Script** when provisioning the VDB. This will provision and move the VDB into ASM disk groups in a

single flow. You must specify the `-noask` option to execute in non-interactive mode. For more information about hook scripts, visit the [Hook Scripts for Automation and Customization](#) article.

Command syntax: `move-to-asm.sh [-noask] [-parallel #] [-dbunique db_unique_name] <data_diskgroup> [<redo_diskgroup>]`

Arguments	Description
<code>-noask</code> [optional]	Do not prompt for confirmation before moving the VDB. The default is to prompt.
<code>-parallel #</code> [optional]	The number of RMAN channels used to move the VDB to ASM. The default is 8.
<code>-dbunique &lt;&gt;</code> [optional]	Unique database name for the resulting physical database. The default is the unique name of the VDB. The <code>-dbunique</code> argument only works if a database with that name that you select already exists.
<code>&lt;&gt;</code> [required]	Target ASM disk group for data, server parameter and control files.
<code>&lt;&gt;</code> [optional]	Target ASM disk group for redo log files. Default is <code>&lt;&gt;</code> .

move-to-asm script

The `move-to-asm.sh` script generates several output files. These files are all written to the working directory of the script:

```
init<oracle_sid>_run<process-id>_moveasm.ora
```

The log file for the operation:

```
move-to-asm.sh_<oracle_sid>_run<process-id>.log
```

The `init.ora` parameter file created for the ASM DB instance:

```
source_init<oracle_sid>.ora
```

The `init.ora` for the source database (from which the VDB was created).

### Finishing steps

The final steps to manually execute are shown when the script completes and included in the script output.

1. For Single Instance only: copy generated `init<ORACLE_SID>.ora` parameter file to the default `$ORACLE_HOME/dbs/init<ORACLE_SID>.ora`

2. Modify initialization parameters to match the original source database parameters, if necessary.

As a convenience to assist with this step, the source database parameters are restored as `source_init<$ORACLE_SID>.ora` in the execution directory. Be sure to copy this file to a safe place *before* deleting the temporary VDB.

The `move-to-asm.sh` script generates several output files. These files are all written to the working directory of the script and should also be copied to a safe place if needed:

```
move-to-asm.sh_<oracle_sid>_run<process-id>.log
```

The log file for the operation:

```
init<oracle_sid>_run<process-id>_moveasm.ora
```

The init.ora parameter file created for the ASM DB instance:

```
source_init<oracle_sid>.ora
```

The init.ora for the source database (from which the VDB was created).

3. Delete the Delphix VDB that was moved.
4. Start up the physical database that will now run on ASM.  
(A RAC database is automatically started up by the `move-to-asm.sh` script using `srvctl` but may have been stopped when the VDB was deleted, if it has the same name.)

Sample execution

```
$ cd toolkit/Delphix_564dc816_d457_6224_1327_4d43fd1b3d97_oracle_cluster/databases/
oracle/RAC2ASM/RAC2ASM1
$ export ORACLE_HOME=/u01/app/oracle/product/12.2.0.1/dbhome_1
$ export ORACLE_SID=RAC2ASM1
$ sh move-to-asm.sh -noask +DATA +REDO
END_OF_SETUP

```

Copy **this** file to a safe location before removing the VDB

- 1) Delete VDB on Delphix.
- 2) Modify initialization parameters to match source and restart.

## Provisioning from a replicated Oracle VDB

This topic describes how to provision from a replicated dSource or virtual database (VDB).

The process for provisioning from replicated objects is the same as the typical VDB provisioning process, except that first you need to select the replica namespace containing the replicated object.

### Prerequisites

- You must have a dSource or VDB that has been replicated from one Delphix Engine to another, as described in [Replication Overview](#)
- The Delphix Engine containing the replicated dSource or VDB must have a compatible target environment that it can use to provision a VDB from the replicated dSource or VDB.

### Procedure

1. On the Delphix Engine containing the replicated dSource or VDB, login to the **Delphix Management** application.
2. In the top menu bar, click **Manage**.
3. Select **Datasets**.
4. From the list of replica namespaces, select the **replica namespace** that contains the dSource or VDB from which you want to provision.
5. The provisioning process is now identical to the process for provisioning standard objects.

### Post-requisites

Once the provisioning job has started, the user interface will automatically display the new VDB in the live system.

## Provisioning a TDE-enabled vPDB to a cluster target

### Overview

Provisioning a Virtual Pluggable Database (vPDB) to a linked RAC container database first involves using the GUI or CLI to specify the vPDB parameters (such as the vPDB name and target container) along with the snapshot to provision from. Once the provision job is started with these parameters, the Delphix Engine does the following:

1. Chooses an available instance from the target cluster and mounts the snapshot files on that instance.
2. Creates and opens (in mount mode) the auxiliary container database on the target instance, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.
3. Completes recovery to bring the auxiliary container database into a consistent state.
4. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
5. Plugs the vPDB into the target database, and opens it in read-write mode on the same target instance used for recovery.
6. Spawns start jobs to open the vPDB in read-write mode on the remaining target instances in parallel.

If the dSource is TDE-enabled, then Delphix will need to perform additional operations to complete the provision of a TDE-enabled vPDB to a TDE-enabled cluster target (indicated in **red**):

1. Chooses an available instance from the target cluster and mounts the snapshot files on that instance.
2. Creates a keystore with the necessary keys to apply encrypted archived log files on the target instance.
3. Creates and opens (in mount mode) the auxiliary container database on the target instance, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.
4. Completes recovery to bring the auxiliary container database into a consistent state.
5. Rotates the vPDB and auxiliary CDB master encryption keys by generating new keys that are unique to the vPDB/auxiliary CDB and not associated with the source PDB or CDB.
6. Exports only the newly generated keys to an exported keyfile to enable unplug.
7. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
8. Imports the vPDB key from the exported keyfile into the target keystore.
9. When provisioning to a vCDB target, converts the auxiliary CDB into the final vCDB and creates the vCDB keystore from the auxCDB keystore.
10. Opens the Keystore on each node.
11. Plugs the vPDB into the target database, and opens it in read-write mode on the same target instance used for recovery.
12. Spawns start jobs to open the vPDB in read-write mode on the remaining target instances.

All the same information needed for a single instance TDE-enabled vPDB provision is also required for a cluster TDE-enabled vPDB provision, specifically the target keystore password, parent keystore path and password, and encryption secret. The keystores root path is required for a cluster provision.

### Shared storage for keystores

In a cluster database, the database files are on shared storage, which is accessible from all instances in the cluster. If the database is encrypted, then the keystore file itself is also located on the operating system. Oracle recommends that the keystore also be on shared storage, on a different disk from the database files. If the keystore is not on shared storage, then it must be copied to all instances in the cluster after any changes, such as importing a key or generating a new key. Similarly, Delphix recommends that the parent keystore specified for the provision also be on shared storage. If not, then the same file must be copied to all of the instances before the vPDB is first provisioned, and any updates to the parent keystore must also be copied to all of the instances before any vPDB refresh or rewind.

As the autologin wallet is located in the same location as the password-based keystore, it should also be on shared storage. For this reason, `local_autologin` wallets will not work properly, as they will be accessed from multiple nodes in the cluster.

### Keystores root path requirements

The artifact directory for a given vPDB is created under the keystores root. As a subsequent operation on the vPDB may choose a different instance than the one used for the initial provision, the artifact directory needs to be accessible from all instances in the cluster. Delphix requires that the keystores root be specified for a TDE-enabled vPDB provision to a cluster target, and furthermore that it be located on shared storage. The engine will validate that this is the case before proceeding with the initial provision.

## Oracle hook operations

### Oracle RAC

When linking from, or provisioning to Oracle RAC environments, hook operations will not run once on each node in the cluster. Instead, the Delphix Engine picks a node in the cluster at random and guarantees all operations within any single hook will execute serially on this node.

Note that the Delphix Engine does not guarantee the same node is chosen for the execution of every hook but does guarantee that Pre-/Post- hook pairs (such as Pre-Sync and Post-Sync) will execute on the same node.

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at `/bin/sh`. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a `bash` binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

### Shell operation tips

#### Using `nohup`

You can use the `nohup` command and process backgrounding from resource in order to "detach" a process from the Delphix Engine. However, if you use `nohup` and process backgrounding, you MUST redirect `stdout` and `stderr`.

Unless you explicitly tell the shell to redirect `stdout` and `stderr` in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either `stdout` or `stderr`. Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your `RunCommand` operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad Examples

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

#### Good Examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs which normally can only be used interactively, such as `ssh`. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Management application and CLI to aid in debugging.

If successful, the script must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

### Example of a RunExpect operation

Start an `ssh` session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
  -re {Password: } {
    send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
  }
  timeout {
    puts "Timed out waiting for password prompt."
    exit 1
  }
}
exit 0
```

## Oracle environment variables

to access the dSource or VDB.

### dSource environment variables

Environment variable	Description
<code>ORACLE_SID</code>	The SID of the dSource
<code>ORACLE_BASE</code>	The home directory of the Oracle software hosting the dSource
<code>ORACLE_HOME</code>	The Oracle Home for the dSource
<code>CRS_HOME</code> (only set for RAC dSources)	The home directory for cluster services hosting the dSource

Environment variable	Description
ORAENV_ASK	Always set to NO
DELPHIX_DATABASE_NAME	The database name reported by Oracle
DELPHIX_DATABASE_UNIQUE_NAME	The database unique name reported by Oracle
DELPHIX_PDB_NAME (only set for PDBs)	The PDB name reported by Oracle

## VDB environment variables

Environment variable	Description
ORACLE_SID	The SID for the VDB
ORACLE_BASE	The home directory for the Oracle software hosting the VDB
ORACLE_HOME	The Oracle Home for the VDB
CRS_HOME (only set for RAC VDBs)	The home directory for cluster services hosting the RAC VDB
ORAENV_ASK	Always set to NO
DELPHIX_DATABASE_NAME	The database name reported by Oracle
DELPHIX_DATABASE_UNIQUE_NAME	The database unique name reported by Oracle
DELPHIX_PDB_NAME (only set for PDBs)	The PDB name reported by Oracle
DELPHIX_MOUNT_PATH	The root of the NFS mount hosting the VDB data
MASKING_CONNECTOR_HOST (only set for masked provisioning)	The host that DMSuite will use for the connector

Environment variable	Description
<div data-bbox="172 389 778 510" style="border: 1px solid #ccc; padding: 5px;">MASKING_CONNECTOR_PORT (only set for masked provisioning)</div>	The port that DMSuite will use for the connector

 PATH and LD\_LIBRARY\_PATH configuration  
PATH is configured by appending the bin directory in the Oracle home for the dSource or VDB.  
LD\_LIBRARY\_PATH is configured by appending the lib directory in the Oracle home for the dSource or VDB.

## Oracle E-Business Suite (EBS) environments and data sources

This section contains the following topics:

## Oracle E-Business Suite and Delphix conceptual overview

This topic provides a conceptual overview of the integration between the Delphix Engine and Oracle E-Business Suite (EBS).

### Why use the Delphix Engine with E-Business Suite?

Oracle E-Business Suite offers a multitude of enterprise resource planning (ERP), supply chain management (SCM), and customer relationship management (CRM) applications useful for running a business. Typical EBS instances are consumed horizontally across an organization but managed on-site by an IT organization. Most businesses hire consultants or in-house developers to customize these instances to fit business needs.

Production EBS instances are critical to many business processes; EBS is expected to be always available and functioning correctly. An IT organization's EBS team is responsible for maintaining this production instance: this team monitors the instance and manages how software modifications are integrated. Common EBS software modifications include patches provided by Oracle or new application logic provided by consultants or in-house developers.

However, before making a software modification to their production EBS instance, most EBS teams vet the modification. These teams typically maintain a series of non-production copies of their production EBS instance to use for the vetting process. To vet a modification, the EBS team will modify a non-production instance in an attempt to identify bugs in the modification that might lead to incorrect functionality, performance regressions, or downtime. Once a modification has been installed and tested successfully, it is considered vetted and the EBS team make the same modification to the production instance.

The problem with this process is that maintaining non-production copies of EBS is costly. EBS teams not only need to provision and maintain resources for each copy, they also must update each copy to match production every time production itself is modified. This process takes two hours at a minimum and can take up to a week or more.

The Delphix Engine can alleviate much of the pain around managing non-production copies of Oracle E-Business Suite. You can link a production EBS instance to the Delphix Engine and use the engine to provision virtual copies. These virtual copies lower storage costs associated with non-production. They also drastically reduce the amount of active attention required from the EBS team. When a change is made to the production EBS instance, the Delphix Engine can synchronize its copy; all virtual EBS instances can then be refreshed to match this new version of the production. The process of refreshing a virtual EBS instance is fully automated, so an EBS team no longer needs to invest copious amounts of time refreshing non-production instances manually.

In addition, the Delphix Engine can take snapshots of virtual EBS instances in known healthy states so that you can easily roll back risky modifications while vetting them. This functionality provides modern version control semantics for a process that previously had none.

### Overview of linking and provisioning EBS

Oracle E-Business Suite is primarily comprised of a database service and a plethora of application services. The Delphix Engine supports the linking and provisioning of all EBS datasets, including the database technology stack (dbTechStack), database, and application files (appsTier). Note that the Delphix Engine can also manage custom extensions and plug-ins.

The process of linking EBS data involves creating multiple dSources:

- a dSource for the dbTechStack
- a dSource for the Oracle database used by EBS
- a dSource for the appsTier

These dSources are collectively referred to as EBS dSources. They are also the source datasets from which you can provision virtual EBS instances.

The process of provisioning a virtual EBS instance involves provisioning from each of these dSources separately to the proper environments in sequence. You can add custom configuration logic to the Delphix Engine for each EBS instance such that the linking, provisioning, and refresh processes are fully automated.

**i** The plugin versions for AppsTier and DB Tech Stack need to be the same, at installation and through the upgrade. Installation and usage of different versions of these plugins are not supported and may encounter operational issues.

### dbTechStack dataset

The source dbTechStack is linked using the Delphix Engine's EBS support: the linking process automatically runs pre-clone logic to ensure EBS configuration is always appropriately staged at the time of data capture. When you provision EBS, the Delphix Engine automates post-clone configuration such that a copy of the dbTechStack is available for use on the target dbTier server with no additional effort. You can add this copy of the dbTechStack to the Delphix Engine as an Oracle installation home and use it to host an EBS virtual database (VDB).

### Database dataset

The database dSource is linked using the Delphix Engine's support for Oracle databases. This dSource contains database data files that EBS is currently using. For more information about managing Oracle databases. When you provision EBS, you will use the Delphix Engine to set up a copy of the EBS database on the target dbTier server. This copy of the database will be used to back virtual EBS instance's appsTier.

### appsTier dataset

The appsTier is linked using the Delphix Engine's EBS support: the linking process automatically runs pre-clone logic to ensure EBS configuration is always appropriately staged at the time of data capture. When you provision EBS, the Delphix Engine will automate post-clone configuration such that a copy of the appsTier is available for use on the target appsTier server. This virtual copy of the appsTier will connect to the provisioned EBS virtual database (VDB).

### How does it work?

The Delphix Engine's linking and provisioning logic follows the Oracle-recommended cloning procedures outlined in the following Oracle Support documents found at <http://docs.oracle.com>:

- Cloning Oracle E-Business Suite Release 12.2 with Rapid Clone (Doc ID 1383621.1)
- Cloning Oracle Applications Release 12 with Rapid Clone (Doc ID 406982.1)

## Oracle E-Business Suite Compatibility Matrix

- Delphix Support Policies specifically list Major and Minor release coverage. If a minor release is listed as covered, then all patch releases under that minor release are certified.
- Support applies to corresponding versions of Community Enterprise Operating System (CentOS) / Oracle Linux (OL)
- 64-bit OS support only

For specific plugin version release notes, see [EBS 12.2 Plugin Release Notes](#).

### Key:

- V2P

## EBS plugin installation

The EBS Plugin is provided as a zip file on the Delphix download site. Follow the steps below to download the plugin:

1. In the web browser, go to the Delphix [download](#) site
2. Login to the download site using email and password credentials.
3. Navigate to the **Delphix Product Releases** folder and select the required Delphix Engine version.
4. Go to `Plugins> EBS> EBS12.2> EBS_Toolkit_<version_number>_for_EBS12.2.zip` folder , then download the zip file, unzip it, and copy both the .json files at your preferred location.

**Note:**

- For a particular version of the EBS plugin, there are two .json files that will be downloaded and the same would be uploaded while installing or upgrading the plugin. Also, you need to upload these .json files in sequential order. For example, for EBS12.2 2.0.1 plugin version you need to upload ebs122-db2.0.1.json first and then ebs122-app2.0.1.json.
  - The plugin versions for AppsTier and DB Tech Stack need to be the same, at installation and through the upgrade. Installation and usage of different versions of these plugins are not supported and may encounter operational issues.
5. Existing users who are planning to upgrade from Plugin version 3.0.x to 4.0.0 need to consider below points:
    - a. Follow the upgrade path available at [EBS Release notes](#)
    - b. For low-privilege users, old sudoers entries need to be updated with the newly provided sudoers entries in both source and target environments prior to upgrade.
    - c. Update the Database VDB Hooks with the newly provided hooks.
    - d. For plugin upgrade and installation steps, refer to [Delphix Engine plugin management](#). Also, refer to [EBS support matrix](#) for upgrade paths.
  6. If you are planning to deploy the EBS 12.2 4.0.0 for the first time in the Delphix Engine, you just need to upload the new plugin and proceed with the Delphix Engine operations.

## Upgrade EBS objects to 6.0

This section focuses on the steps to be taken post-upgrade to Delphix 6.0 release for both EBS 12.1 and EBS 12.2 for all dSources and VDBs present on the Delphix Engine.

### Uploading a plugin

After upgrading to the required DE version 6.0.3 or later, if you need to upgrade or install a new plugin, follow the steps mentioned in [EBS Plugin Installation](#).

### Post upgrading to 6.0.3.0 or later

#### EBS 12.2 plugin

This section focuses on the steps taken after upgrading to the Delphix 6.0.3.0 release or later, for all the users who intend to use plugin version 2.0.0 or 2.0.1 for EBS 12.2.

Pre-requisites for the existing users:

To successfully upgrade to Delphix Engine 6.0.3.0 or later with EBS 12.2 plugin version 3.0.0, the following conditions must be fulfilled:

- The user must be on or upgrade to the 2.0.0/2.0.1 version before moving to 3.0.0 on the Delphix Engine. Refer [Plugin Upgrade Path for EBS 12.2 Customers](#) for all the recommended upgrade paths.
- All datasets on Delphix Engine must be in a disabled state.

Post upgrade steps:

1. Verify the plugin version under **Manage > Plugins** section. It should show as 3.0.0.
2. Refresh all the environments on the Delphix Engine.
3. Users who intend to use low-privileged user, (for example, "delphix\_os") should follow the environment configuration mentioned [here](#) and steps 4 and 5 below.
4. All the EBS dSources and VDB/vFiles should edit the Environment User under the Configuration → Source to "delphix\_os".
5. Users who intend to use low-privileged user, must update the "Privileged OS User" field on the dSource/VDB provision wizard to high privileged user (user who should own the file system).
6. Enable all the EBS dSources - dbTechStack, Database, and appsTier.
7. Take new snapshots for all the enabled EBS dSources.
8. Enable all the EBS VDB/vFiles as per the following sequence: (1) dbTechStack (2) Database (3) appsTier
9. Under **Custom > Configuration** tab for dbTechStack vFiles, update the value for the "Target APPS Password" field to the value similar to the "Target APPS Password" field as provided under appsTier vFiles.
10. Modify the database hooks. Follow the steps under [Provisioning a Virtual EBS R12.2 instance](#) to configure the hooks.
11. Take new snapshots for all the enabled EBS VDB's.
12. To refresh the VDB's, follow the steps and instructions for [Refreshing a virtual EBS instance](#).

## Upgrade objects to 5.3

### Post upgrade to 5.3.2.0

This section focuses on steps to be taken post-upgrade to the Delphix 5.3.2.0 release for all customers who intend to use WebLogic password change feature for EBS 12.2 release.

1. Disable all the virtual datasets created on Delphix Engine in the following order:
  - a. appsTier vFiles
  - b. VDB utilized by your EBS instance
  - c. dbTechStack vFiles
2. Disable all the EBS dSource created on Delphix Engine once you have disabled all three EBS virtual datasets in the above step.
3. Upgrade Delphix Engine to 5.3.2.0 release and upload EBS 1.4.0 plugin release.
  - a. Go to Manage → Plugins
    - i. Upload a plugin file to upgrade existing toolkit by clicking plus (+) symbol.
4. Refresh all host environments added on the Delphix Engine
  - a. Go to Manage → Environments
    - i. From the symbol (...) located in the upper left-hand corner, select Refresh All.
5. Change the Weblogic admin password on EBS appsTier vFile.
  - Select the appsTier vFiles hosting your virtual EBS database.
  - Go to Configurations → Custom
  - Update “**Target Weblogic AdminServer Password**” field with the password you would like to set for EBS appsTier.
6. Enable all the EBS dSource created on Delphix Engine.
7. Enable all the virtual datasets created on Delphix Engine in the following order:
  - a. dbTechStack vFiles
  - b. VDB utilized by your EBS instance
  - c. appsTier vFiles
8. Verify the changed WebLogic password by logging into the WebLogic console.

### Post upgrade to 5.3.1.0

This section focuses on steps to be taken post-upgrade to the Delphix 5.3.1.0 release for all customers who intend to use sudo privileges for EBS 12.1 release.

1. Create a low-privileged OS account (delphix\_os) in source and target environments.
2. Steps and configuration required for a low-privileged account to perform delphix privileged operations are outlined in [Requirements for Unix environments](#).
3. Push the privilege elevation script "DLPX\_DB\_EXEC" to both and target environments as per the steps outlined in [Privilege script](#).
4. For all 12.1 EBS appsTier dSource :
  - a. Go to Configuration >Source
    - i. Update Environment User value to low privileged account (delphix\_os).
  - b. Go to Configuration>Custom
    - i. Update Privileged OS Account with the value for high privileged user (applmgr).
5. For all 12.1 EBS appsTier vFile:
  - a. Go to Configuration>Source
    - i. Update Environment User value to low privileged account (delphix\_os).
  - b. Go to Configuration>Custom
    - i. Update Privileged OS Account with the value for high privileged user (applmgr).
6. For both source and target environment:

- a. Go to Manage>Environments
  - i. Add low privileged OS user (delphix\_os) in Environments Users section by clicking plus (+) symbol.
  - ii. Mark low-privileged OS user (delphix\_os) as the primary user.
  - iii. Remove the high privileged OS user (applmgr) from the Environments Users section.

## Upgrade EBS objects to 5.2

This section focuses on steps to be taken post-upgrade to the Delphix 5.2 release for all dSources and VDBs present on the Delphix Engine.

### 1. For all 12.1 EBS apps Tier Dsource :

Go to Configuration → Custom

- Update context\_name with the Context value of the application tier
- Update apps password with the value of the dsource.
- Take a new snapshot after updating the above parameters

### 2. For all 12.1 and 12.2 EBS Database VDB:

- Update the pre snapshot hook as follows

```
# NOTE: Ensure the below environment variables will be set up correctly by
the shell. If not, hardcode or generate the values below.
# CONTEXT_NAME=${ORACLE_SID}_${hostname -s}
# APPS_PASSWD=<source apps passwd>
# TARGET_APPS_PASSWD=<new apps password>

timeout=3600
waittime=0
. ${ORACLE_HOME}/${CONTEXT_NAME}.env

testAppsPassword() {
    local passwordInQuestion=$1
    ERROR=`sqlplus "apps/${passwordInQuestion}" <<< "exit;"`

    grep ORA-01017 <<< ${ERROR} >/dev/null && return 1
    return 0
}

testAppsPassword ${SOURCE_APPS_PASSWD}
testResult=$?

if [[ ${testResult} == 0 ]]; then
    APPS_PASSWD=${SOURCE_APPS_PASSWD}
else
    APPS_PASSWD=${TARGET_APPS_PASSWD}
fi

while [[ -f "${ORACLE_HOME}/.delphix_adpreclone.lck" || "$(ps -Ao args |
grep "^${ORACLE_HOME}" | grep -v grep | grep "adpreclone")" ]]; do
if [[ $waittime -gt $timeout ]]; then
    echo "Another adpreclone process is still running from last 60
mins.Delphix cannot proceed until it is complete. Exiting Now."
    exit 1
fi
    echo " Another adpreclone process is running. waiting for the process
to complete before starting adpreclone of the database..."
    (( timeout += 10 ))
```

```
    sleep 10
done
echo "No other adpreclone process is running on database, proceeding ...."
. ${ORACLE_HOME}/${CONTEXT_NAME}.env
${ORACLE_HOME}/perl/bin/perl ${ORACLE_HOME}/appsutil/scripts/${CONTEXT_NAME}/adpreclone.pl database <<-EOF
${APPS_PASSWD}
EOF
```

### 3. For all 12.1 EBS apps Tier VDB :

Go to Configuration → Custom

- Update system password with the system password corresponding to the database.
- Take a new snapshot after updating the above parameters

## Oracle EBS R12.2

This section contains the following topics:

- [Source EBS R12.2 instance requirements](#)
- [Virtual EBS R12.2 instance requirements](#)
- [Remote logging](#)
- [Preparing a source EBS R12.2 instance for linking](#)
- [Linking a source EBS R12.2 instance](#)
- [Preparing target EBS R12.2 environments for provisioning](#)
- [Provisioning a virtual EBS R12.2 instance](#)
- [Linking & provisioning TDE Enabled \(19c\) Oracle EBS PDB](#)
- [EBS database port flexibility/customization](#)

## Source EBS R12.2 instance requirements

The Delphix Engine supports linking a variety of versions and configurations of Oracle E-Business Suite R12.2. Below, detailed compatibility notes are outlined.

Note that minor releases of EBS are not certified for Delphix Engine compatibility individually; major release support implies support for any minor release.

To review the requirements for provisioning a virtual EBS R12.2 instance from the Delphix Engine, see [Virtual EBS R12.2 instance requirements](#).

### Operating systems

- Linux – SLES 9, 10, 11; RHEL 5, 6, 7, OL 5, 6
- Solaris - SPARC 9, 10, and 11

### **AIX and HP-UX not supported**

The Delphix Engine does not support linking EBS instances running on AIX or HP-UX.

### dbTier requirements

#### Supported topologies

- Oracle single-instance (SI) dbTechStack and Database
  - Oracle11gR2 v11.2.0.4
  - Oracle12cR1 v12.1.0.2
  - Oracle19c MT v19.3.0.0
- Oracle RAC dbTechStack and Database
  - Oracle11gR2 v11.2.0.4
  - Oracle12cR1 v12.1.0.2

### Caveats

The Delphix Engine does not provide support for linking an EBS R12.2 instance utilizing custom context variables maintained in the EBS context file.

## Virtual EBS R12.2 instance requirements

The Delphix Engine supports provisioning a variety of versions and configurations of Oracle E-Business Suite R12.2. Below, detailed compatibility notes are outlined.

Note that minor releases of EBS are not certified for Delphix Engine compatibility individually: major release support implies support for any minor release.

To review the requirements for linking an EBS R12.2 instance to the Delphix Engine, see [Source EBS R12.2 instance requirements](#).

### Operating systems

- Linux - SLES 9, 10, 11; RHEL 5, 6, 7, OL 5, 6
- Solaris - SPARC 9, 10, and 11

#### **AIX and HP-UX not supported**

The Delphix Engine does not support provisioning EBS instances to AIX or HP-UX.

### dbTier requirements

#### Supported topologies

- Oracle SI dbTechStack and Database
  - Oracle11gR2 v11.2.0.4
  - Oracle12cR1 v12.1.0.2
  - Oracle19c MT v19.3.0.0

#### **Oracle RAC not supported**

The Delphix Engine does not support provisioning Oracle RAC dbTechStack for use with Oracle E-Business Suite. However, you may provision an Oracle SI dbTier from a linked EBS RAC dbTier instance. During the provisioning process, the Delphix Engine will relink the dbTechStack for use with an Oracle SI database and scale down the Oracle RAC database to an Oracle SI database.

### appsTier requirements

#### Supported topologies

- Single-node appsTier
- Multi-node appsTier with a shared APPL\_TOP

#### **Non-shared APPL\_TOP not supported**

The Delphix Engine does not provide support for provisioning a multi-node appsTier where the APPL\_TOP is not shared between nodes.

#### **i appsTier topology is configurable**

The appsTier topology of the virtual EBS instance does NOT need to match the appsTier topology of the source EBS instance. The Delphix Engine will automate scale up or scale down logic as required during provisioning.

### Caveats

The Delphix Engine will only register the default WLS-managed server for each server type during multi-node appsTier provisioning. Additional WLS managed servers need to be registered manually or as a **Configure clone** hook.

## Remote logging

Remote Logging for EBS 12.2 Plugin adds the following options to provide enhanced logging:

- set debug log levels
- set active log file size
- set log retention levels

You can modify the parameters defined in the `ebs_plugin.conf` file located in remote target host at

`<Toolkit directory>/<Delphix_COMMON>/plugin/ebs122-vsdk-db_9f7f5a63-1da7-495c-80df-e0fa61941342/ebs_plugin.conf` for DbTechStack and `<Toolkit directory>/<Delphix_COMMON>/plugin/ebs122-vsdk-app_403e7034-0028-4200-ad0b-15031f0f8871/ebs_plugin.conf` for appsTier to configure the logging mechanism.

### Setting log levels (level)

You can set log levels for plugin-generated logs by setting the parameter `level` in the `ebs_plugin.conf` file. Higher logging levels will help to expedite debugging issues. There are two levels of logging: info and debug.

#### Log level description

- `level=INFO`: This level will print only informational logs. This is the default log level.
- `level=DEBUG`: This level will print informational logs and debug statements.

### Setting maximum size of active log file (logFileSize)

You can set this parameter inside the `ebs_plugin.conf` file to set the maximum size of the active log file in MB. Once this limit is reached, the plugin rotates the log as per the retention property defined below. The minimum value of this parameter is 1 MB and the maximum value is 10 MB. This parameter only takes in a positive integer value. The default value is 1 MB.

### Setting log retention levels (retention)

You can set a retention level for diag logs (`diag.log`) using parameter `retention` in the `ebs_plugin.conf` file. As per this parameter, the log files are moved (archived), renamed, or deleted once they reach the value set in the `logFileSize` parameter. New incoming log data is directed into a new fresh file (at the same location).

By default, this value will be set to a minimum value of 2. The user can change this value and set its value within the range 2 and 50. For example; if retention is set to 4, the plugin will have the following log files: `diag.log`, `diag.log.1`, `diag.log.2`, `diag.log.3`, `diag.log.4`.

- File `diag.log` is the active log file.
- File `diag.log.1` is the most recent archive log file
- File `diag.log.4` is the oldest one

### ebs\_plugin.conf file

```
#
# This flag will set the debug level of plugin logs on the remote server. There are
# two levels:
# Info
# Debug
```

```
# The above are the only valid values that can be assigned. If any other value is
assigned, the plugin will set the
# default level as Info. the string is case insensitive so info, Info and INFO are
acceptable.
#
level=INFO

#
# This parameter will set the maximum size of the active log file in MB. Once this
limit is reached, the plugin will
# rotate the log as per the retention property defined below. The minimum value of
this parameter is 1 MB and maximum
# value is 10 MB. This parameter only takes in a positive integer value. The default
value is 1 MB
# logFileSize=<positive integer>
#
logFileSize=1

#
# Whenever the size of diag.log file exceeds the value provided by logFileSize
parameter then the plugin will
# rename the active log file to diag.log.<number> and a new log file with name
diag.log will be
# generated. For example, if LogRetention is set to 4, the plugin will have the
following log files: diag.log,
# diag.log.1, diag.log.2, diag.log.3, diag.log.4.
# File diag.log.4 will be the oldest one.
# File diag.log.1 will be the most recent archive log file.
# File diag.log will be the active log file.
# The minimum and default value for retention flag is 2.
# retention=<positive integer>
#
retention=2
```

## Preparing a source EBS R12.2 instance for linking

This topic outlines the prerequisites for linking an EBS R12.2 instance to the Delphix Engine.

Ensure your EBS R12.2 instance is supported

See [Source EBS R12.2 instance requirements](#) to ensure you can link your EBS R12.2 instance to the Delphix Engine.

Ensure your EBS 12.2 environments comply with Oracle's documentation

Your environments must comply with Oracle's requirements for installing EBS. These requirements are outlined on **Oracle E-Business Suite Release 12 Installation Guidelines (Doc ID 405565.1)** found at <https://support.oracle.com>

Prepare the dbTier for linking

Delphix engine's Unix environment requirements

The dbTier must meet the source requirements outlined in [Requirements for Unix environments](#). These requirements are generic to all source Unix environments added to the Delphix Engine.

`oracle` user

The Delphix Engine must have access to an `oracle` user on the dbTier.

- This user should be a member of both the EBS `dba` and `oinstall` groups.
- The user should own the stage directory for DBTechStack and database files that will be cloned.
- Ensure that the "expect" utility exists on the remote host.

dbTechStack binary permissions

Verify that the `oracle` user described above has read permissions at the group level for:

- `$ORACLE_HOME/bin/nmb`
- `$ORACLE_HOME/bin/nmhs`
- `$ORACLE_HOME/bin/nmo`

The Delphix Engine's Oracle database requirements

The dbTier must meet the source requirements outlined in [Oracle support and requirements](#). These requirements are generic to all Unix environments containing an Oracle database to be linked.

Prepare the appsTier for linking

Delphix Engine's Unix environment requirements

The appsTier must meet the source requirements outlined in [Requirements for unix environments](#). These requirements are generic to all source Unix environments added to the Delphix Engine.

`applmgr` user

The Delphix Engine must have access to an `applmgr` user on the appsTier.

- This user should be a member of the EBS `oinstall` group.
- The user should own the stage directory for Appstier files that will be cloned.

#### delphix\_os OS user account

In order to separate authentication and perform privileged operations with a non-privileged OS account, first create an OS user account (i.e. "delphix\_os") on the EBS DB Tier and appsTier node to be used as a source.

This user is easily created by the `createDelphixOSUser.sh` (located below on this page) script.

- The primary OS group of the Delphix Engine software owner account's (i.e. `delphix_os`) should be the same as the EBS Database/AppsTier software owner account (i.e. `oravis` or `applmgr`).
- Primary group = Oracle Install Group (typically `oinstall`), secondary group = OSDB Group (typically `dba`). There are lots of cases where the OS group named `dba` fills this role, so be sure to check the group membership of the EBS Database and AppsTier software owner account.
- Please note, the non-privileged OS account must have the **same** group as assigned to EBS Database or AppsTier privileged account (like `oravis` or `applmgr`).

#### Host requirements:

To accomplish necessary tasks on the EBS Database and appsTier source hosts, the Delphix OS user account (henceforth referred to as "delphix\_os") requires privilege elevation specifications.

Here is an example specification for the "sudo" privilege elevation utility, using the "visudo" to edit the "sudoers" configuration file. This specification makes the following assumptions:

- OS = Linux
  - OS account owning Oracle EBS Database Tier is named **oravis**
  - OS account owning Oracle EBS appsTier is named **applvis**
- OS = Solaris
  - OS account owning Oracle EBS Database Tier is named **oravis**
  - OS account owning Oracle EBS appsTier is named **oravis**
- EBS Database and appsTier system base directory is **/u01/oracle/VIS**. This can be prefixed before all the below-mentioned commands to ensure the same are being executed from relevant paths.

 The following sudoers entry is only for template purpose. Modify the path in the below sudoers entry with the appropriate binary paths of your environment.

## Sudoers entry for Linux -

**Entries required for linking via low privileged user (delphix\_os):**

EBS DB Tier

```

Defaults:delphix_os !requiretty
delphix_os ALL=NOPASSWD: /bin/su -

adpreclone.pl appsTier*

```

Requirement for privilege elevation script: DLPX\_DB\_EXEC

In order to elevate privileges from a non-privileged OS account (like delphix\_os) to a privileged OS account (like applmgr), we need to push a privilege elevation script (**dlpx\_db\_exec**) up into the Delphix virtualization engine to become part of the Delphix common plugin.

Why we need DLPX\_DB\_EXEC

Some customers want to use low privilege users to perform delphix operations like linking and provisioning. It means their low privilege user should have sudo permissions to execute EBS application and DB related commands. The privilege elevation profile script **dlpx\_db\_exec** allows them to execute commands that require superuser privileges on customer source and target machines.

The privilege elevation script **dlpx\_db\_exec** can be created or pushed to Delphix Engine using Web API calls, CURL or dxtoolkit.

For steps on creating a Privilege Elevation Profile please refer to [CLI Cookbook: How to create or edit a privilege elevation profiles and profile scripts](#)

#### Content of DLPX\_DB\_EXEC Privilege Elevation Profile:

```
#!/bin/sh
#
# Copyright (c) 2018 by Delphix. All rights reserved.
#
# This script allows customization of command execution with an alternate user
# account.
# Arg $1 contains "-u<optional user account>" for the desired user under
# which database commands will be executed.
# By default this argument is ignored and the script is executed as the default
# account.
#
if [[ $1 != -u* ]]; then
    echo "Incorrect command line parameters, -u<optional user account> is required as
the first parameter"
    exit 1
fi
user_id=`echo $1 | sed -e "s/^-u//"`
shift 1
if [[ $user_id != "delphix_os" ]]; then
    command=$(printf "%s " "$@" )
    sudo su - $user_id -c "$command"
else
    $@
fi
```

Below is an example of how we can push privilege elevation script “dlpx\_db\_exec” on a customer Delphix Engine:

- Create a session to Delphix Engine as Delphix os user:

```
curl -i -c cookies.txt -X POST -H "Content-Type:application/json" http://
<Delphix-Engine>/resources/json/delphix/session -d '{
  "version":{
    "minor":11,
    "major":1,
    "micro": 5,
    "type":"APIVersion"
  },
  "type":"APISession"}'
```

Note: The API Version needs to be identified as per the Delphix Engine installed at the customer site.

- Login to Delphix Engine as Delphix OS User:

```
curl -i -c cookies.txt -b cookies.txt -X POST -H "Content-Type:application/json" http://<Delphix-Engine>/resources/json/delphix/login -d '{
  "password":"delphix",
  "type":"LoginRequest",
  "target":"DOMAIN",
  "username":"delphix_admin"
}'
```

- Push DLPX\_DB\_EXEC contents to Delphix Engine:

```
curl -i -b cookies.txt -X POST -H "Content-Type:application/json" http://<Delphix-Engine>/resources/json/delphix/host/privilegeElevation/profileScript/HOST_PRIVILEGE_ELEVATION_PROFILE_SCRIPT-7 -d '{
  "type": "HostPrivilegeElevationProfileScript",
  "contents": "#\n# Copyright (c) 2018 by Delphix. All rights reserved.
\n#\n#\n# This script allows customization of command execution with an
alternate user\n# account.\n\nif [[ $1 != -u* ]]; then\n    echo \"Incorrect
command line parameters, -u<optional user account> is required as the first
parameter\"\n\n exit 1\n\nfi\n\nuser_id=`echo $1 | sed -e \"s/^-u//\"`\n\n\nshift
1\n\nif [[ $user_id != \"delphix_os\" ]]; then\n\ncommand=$(printf \"%s \" \"$@\")
\n\nsudo su - $user_id -c \"$command\"\n\n\nelse\n\n$@\n\nfi\n\n"
}'
```

## Linking a source EBS R12.2 instance

This topic describes the process of linking an EBS R12.2 instance and creating the necessary dSources.

### Prerequisite

Prepare your source EBS R12.2 instance for linking by following the outline in [Preparing a Source EBS R12.2 instance for linking](#)

### Procedure

#### Link the Oracle database

1. Link the Oracle database used by EBS, as outlined in [Linking an Oracle data source](#)
2. Link the Oracle Pluggable database for 19c MT, as outlined in [Linking an Oracle pluggable database](#)

#### Link the EBS dbTechStack

### Prerequisite

Upload the EBS 12.2 dbTechStack plugin and refresh the environments during the preparation of the source environment. For more information, see [Upgrade EBS objects to 6.0](#)

For successful linking of DBTECHSTACK from the standby site, follow any one of the procedures below:

- Place the physical standby database in READ ONLY/ READ ONLY WITH APPLY mode and run linking of source DBTECHSTACK. Even during subsequent snapsync operations, you have to make sure that the standby database container & its PDB is in READ ONLY / READ ONLY WITH APPLY mode.  
**Note:** Make sure that the PDB is in READ ONLY mode, also the two default EBS PDB services `ebs_` and should be in READY STATE. Linking will fail if the PDB is not in READ ONLY mode.
- Perform the linking of dbTechStack(ORACLE\_HOME) from the primary source site which is in READ\_WRITE mode.

#### **Note:**

- Before DBTechStack linking, to ensure that the hook operation succeeds during database provision, the ETCC patch level should be the latest. In the configure clone 1 hook `adcfgclone dbconfig` will perform the ETCC patch level check and will fail if it's not the latest.
- While linking using the EBS plugin, the plugin runs `adpreclone.pl dbTier` in the background, which asks for apps database user password and connects with standby DB. If database is in MOUNT state then linking fails, as apps schema will not be able to login into standby DB.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **source dbTier environment** containing the source dbTechStack.  
**Note:** If you are linking from a RAC dbTier, select the environment for a single running node of the RAC cluster.
5. Click the **Environment Details** tab.
6. If the `oracle` environment user described in [Preparing a source EBS R12.2 instance for linking](#) is not already added to the Delphix Engine, add the user.
7. Click the **Databases** tab.
8. Click the **Plus** icon within **E-Business Suite R12.2 dbTechStack** section under installations.
9. **Add Database** dialog box pops to add source config for dbTechStack.
10. Provide a user-defined name to the `Database Name` field and Oracle base install directory in the `Path` field.

11. Click on the **Add** button to successfully add the source config.
12. Re-check the **E-Business Suite R12.2 dbTechStack** section under installations for the `Add dSource` option mapped to the source config that is added in the above step.
13. Click **Manage > Datasets**.
14. Click the **Plus** icon next to Datasets and select **Add dSource**.
15. In the **Add dSource wizard**, select the Linked dSource as the type.
16. Enter the **EBS-specific parameters** for your dbTechStack.
17. These parameter values will be used when `adpreclone.pl` is run. Ensure that the **DB Tier Context Name** uses the short hostname.
18. Select an Environment user.
19. **Privileged OS Account (Optional)** field should contain a high privileged user when the low privileged user is being used for linking.
20. Provide source oracle home directory name relative to oracle base installation directory in Oracle Home input field.
21. In the **DB Tier** Context Name field, provide the source context name; To get the DB Tier context name on source side:
  - For Oracle 12.1.0.2 version,

```
cd $ORACLE_HOME
source SID_hostname.env file
echo $CONTEXT_NAME
```

Below is an example, Consider VISDB as the database SID and tavsrc-db as the short hostname.

```
[oravis@tavsrc-db VIS]$ source /u01/oracle/VIS/12.1.0.2/VISDB_tavsrc-
db.env
[oravis@tavsrc-db VIS]$ echo $CONTEXT_NAME
VISDB_tavsrc-db
```

**Source Environment**  
tavsrc-db.dlpxdc.co

**Data Type**  
AppData

**Environment User**

oravis

**Privileged OS Account (Optional)**

This privileged unix username will be used to link EBS dbTechStack. The privileged unix username should begin with a lower case letter or an underscore, followed by lower case letters, digits, underscores, or dashes. They can end with a dollar sign. Leave this field blank if you do not want to use privilege elevation.

Oracle Home \*

12.1.0.2

Path where ORACLE\_HOME will be relative to the dataset home being linked.

DB Tier Context Name \*

VISDB\_tavsrc-db

This will be used to prepare the source environment for linking and taking snapshots.

### APPS Password credentials

This will be used to prepare source environment for linking and taking snapshots.

**Username and Password**

User name

Password \*

....

### Paths to exclude

This will be used to specify relative path(s) to exclude while linking DBTechstack.

data

Delete

oralInventory

Delete

Cancel

Back

Next

Submit

1.1 TUNEBSDB\_TX

Timeflow      Status      Configuration

Source      Policies      Masking      Hooks      Custom

**Privileged OS Account (Optional)**

**Oracle Home**  
product/12.1.0.2/DbHome\_1

**DB Tier Context Name**  
TUN1\_tristexadb01

**APPS Password**  
\*\*\*\*\*

**Paths to exclude**

- checkpoints
- log
- tfa
- audit
- AUDIT\_DIR
- agent1310
- patchdepot
- cfgtoollogs
- admin
- diag
- export
- maintain

- For multi-tenant database, CONTEXT\_NAME will be (<PDB\_NAME>\_<short hostname>)
  - For RAC, CONTEXT\_NAME will be <INSTANCE\_SID>\_<HOSTNAME>  
For example: VIS2\_exaukdb02
- Note:** When preparing the source Oracle RAC system for cloning, make sure that the linking is performed against the primary database node.

22. Provide apps schema password in the **Apps Password Credentials** section by selecting the **Username** and **Password** from the dropdown, leaving the username field empty.
23. Exclude the EBS database's data files if they are stored underneath the Oracle base install directory.
24. These data files will be linked with the database instead of with the dbTechStack. Add the "relative path" to the data files to the **Paths to Exclude** list. If the audit files (located under \$ORACLE\_HOME/rdbms/audit) are large in size, the path of these files could also be excluded so as to avoid dbTechStack timeout issues during provisioning.  
**Note:** Ensure that you add the relative paths and NOT the absolute paths. For example, if you want to exclude the /u01/oracle/VIS/data path, then add "data" only under the **Paths to Exclude** list. Here, /u01/oracle/VIS/data is the absolute path and "data" is the relative path to be added.
25. Click **Next**.
26. Enter a **dSource Name**.
27. Select a **Database Group** for the dSource.
28. Click **Next**. Adding a dSource to a database group enables you to set Delphix Domain user permissions for that dSource's objects, such as snapshots.
29. Select a **SnapSync** policy.

30. Click **Next**.
31. Enter any **custom pre or post sync logic** as Pre-Sync or Post-Sync hook operations. Remember that `adpreclone.pl dbTier` is already run prior to every Snapshot of the dbTechStack. The Pre-Sync hook operations will be run prior to running the `adpreclone.pl` tool.
32. Click **Next**.
33. Review the **dSource Configuration** and **Data Management** information, and then click **Finish**. The Delphix Engine will initiate two jobs to create the dSource, **DB\_Link** and **DB\_Sync**. You can monitor these jobs by clicking **Active Jobs** in the top menu bar, or by selecting **System > Event Viewer**. When the jobs have completed successfully, the **files** icon will change to a **dSource** icon on the **Environments > Databases** screen, and the dSource will be added to the list of **Datasets** under its assigned group.

Link the EBS appsTier

Prerequisite

Upload the EBS 12.2 dbTechStack plugin and refresh the environments during the preparation of source environment. For more information, see [Upgrade EBS Objects to 6.0](#)

1. Login to the **Delphix Management** application using **Delphix Admin** credentials.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **source appsTier environment**.  
**Note:** If you are linking from a multi-node appsTier, select the environment for the node on which EBS admin services reside.
5. Click the **Environment Details** tab.
6. If the `applmgr` environment user described in [Preparing a Source EBS R12.2 Instance for Linking](#) is not already added to the Delphix Engine, add the user.
7. Click the **Databases** tab.
8. Click the **Plus** icon within **E-Business Suite R12.2 appsTier** section under installations.
9. **Add Database** dialog box pops to add source config for dbTechStack.
10. Provide a user-defined name to the ``Database Name`` field and Oracle base install directory in the ``Path`` field.
11. Click on the **Add** button to successfully add the source config.
12. Re-check the **E-Business Suite R12.2 appsTier** section under installations for the **Add dSource** option mapped to the source config that is added in the above step.
13. Click **Manage > Datasets**.
14. Click the **Plus** icon next to Datasets and select **Add dSource**.
15. In the **Add dSource wizard**, select the Linked dSource as the type.
16. In the **Add dSource wizard**, select the **appsTier files source** you just created.
17. Enter the **EBS-specific parameters** for your appsTier. These parameter values will be used when `adpreclone.pl` is run.

18. Select an Environment User.
19. **Privileged OS Account (Optional)** field should contain a high privileged user when the low privileged user is being used for linking.
20. Provide the apps schema password in the **Apps Password** section by choosing the **Username** and **Password** from the dropdown, leaving the username field empty.
21. Provide the weblogic password in the **Weblogic AdminServer Password** section by choosing the **Username** and **Password** from the dropdown, leaving the username field empty.
22. Add the "relative paths" of files to exclude to the **Paths to Exclude** list.
23. Exclude the non-edition file system, instance directories, FMW home directories and Patch file system EBSapps directory which will be recreated when provisioning a virtual EBS appsTier. These paths should typically include:

- `fs_ne`
- `fs1/inst`
- `fs2/inst`
- `fs1/FMW_Home`
- `fs2/FMW_Home`
- `fs2/EBSapps` or `fs1/EBSapps` depending on patch FS in your environment.
- `EBSapps.env`

You can exclude all other directories or files placed in \$APPS\_BASE path.

**Note:** Ensure that you add the relative paths and NOT the absolute paths. For example, if you want to exclude the `/u01/oracle/VIS/fs1/inst` path, then add "`fs1/inst`" only under the **Paths to Exclude** list.

Here, `/u01/oracle/VIS/fs1/inst` is the absolute path and "`fs1/inst`" is the relative path to be added.

24. Click **Next**.
25. Enter a **dSource Name**.
26. Select a **Database Group** for the dSource.
27. Click **Next**. Adding a dSource to a database group enables you to set Delphix Domain user permissions for that dSource's objects, such as snapshots.
28. Click **Next**.
29. Select a **SnapSync** policy.
30. Click **Next**.
31. Enter any **custom pre- or post-sync logic** as Pre-Sync or Post-Sync hook operations. Remember that `adpreclone.pl appsTier` is already run prior to every SnapSync of the appsTier. The Pre-Sync hook operations will be run prior to running the `adpreclone.pl` tool.
32. Click **Next**.
33. Review the **dSource Configuration** and **Data Management** information, and then click **Finish**. The Delphix Engine will initiate two jobs to create the dSource, **DB\_Link**, and **DB\_Sync**. You can monitor these jobs by clicking **Active Jobs** in the top menu bar, or by selecting **System > Event Viewer**. When the jobs have completed successfully, the **files** icon will change to a **dSource** icon on the **Environments > Databases** screen, and the dSource will be added to the list of **Datasets** under its assigned group.

## Preparing target EBS R12.2 environments for provisioning

This topic outlines the prerequisites for provisioning a virtual EBS R12.2 instance to target environments.

Ensure your target EBS R12.2 instance is supported

See [Virtual EBS R12.2 instance requirements](#) to ensure you can provision your EBS R12.2 instance.

Ensure your EBS 12.2 environments comply with Oracle's documentation

Your environments must comply with Oracle's requirements for installing EBS. These requirements are outlined on **Oracle E-Business Suite Release Notes, Release 12.2 (Doc ID 1320300.1)** found at <https://support.oracle.com>

 Oracle has released an E-Business Suite Pre-Install RPM (available on ULN and public yum) that includes all required RPMs for both the appsTier and dbTier of an R12.2 installation. Details can be found in **Oracle E-Business Suite Installation and Upgrade Notes Release 12 (12.2) for Linux x86-64 (Doc ID 1330701.1)** found at <https://support.oracle.com>.

Prepare the dbTier for provisioning

Delphix Engine's Unix environment requirements

The dbTier must meet the target requirements outlined in [Requirements for Unix Environments](#). These requirements are generic to all target Unix environments you add to the Delphix Engine.

`oracle` User

The Delphix Engine must have access to an `oracle` user on the dbTier.

- This user should be a member of both the EBS `dba` and `oinstall` groups.
- This user will be given proper permissions to manage the dbTechStack and database.
- Ensure that the "expect" utility exists on the remote host.

`oraInst.loc`

An `oraInst.loc` file must exist on the dbTier prior to provisioning. This file will specify where the `oraInventory` directories live or where they should be created if they do not already exist.

The `oraInst.loc` file is typically located at `/etc/oraInst.loc` on Linux or `/var/opt/oracle/oraInst.loc` on Solaris. Ensure that the `oraInventory` to which this file points is writable by the `oracle` user.

Consult Oracle EBS documentation for more information about where to place this file on your dbTier and what this file should contain.

### Oracle Central Inventory

The Oracle Central Inventory is a repository for all Oracle products (software) installed on a system. Since the Central Inventory consists of system-specific information, it is required that the Central Inventory be saved on a local non-shared directory on the system. While software can be shared across nodes, the inventory should be local to each system. The global inventory/central inventory(`oraInventory`) for each node should be on a local file system other than Delphix mount base path.

For more info, see the following notes

- **Note 360079.1- Global and Local Inventory explained.**
- **Note 564192.1- FAQs on Central Inventory and Oracle Home Inventory (Local Inventory) in Oracle RDBMS.**
- **Note 834894.1- How to Create a Clean oraInventory in Release 12?**
- **Note 742477.1 - How to create, update or rebuild the Central Inventory for Applications R12?**
- **Note 295185.1- How to Recreate the Global oraInventory?**

/etc/hosts

Use the following to verify hostname settings:

**For Oracle Linux 5, 6, and 7, and Red Hat Enterprise Linux 5, 6, and 7:**

- Verify that the /etc/hosts file is formatted as follows:

```
127.0.0.1 localhost.localdomain localhost
[ip_address] [node_name].[domain_name] [node_name]
```

 Hostname and its IP address of Database host and Appstier host(s) (primary and secondary hosts for multinode) should be added in the `/etc/hosts` file of all the Database, host, Appstier host(s) (primary and secondary hosts for Multinode).

These correct entries are required to avoid adcfgclone timeout issue on the prompt for "**Target System Domain Name**".

Clean up before provisioning option

If you plan to utilize the Cleanup Before Provision option available during dbTechStack provisioning, the Delphix Engine requires the Database Oracle Home to be patched with Oracle Universal Installer (OUI) version 10.2 or above. You can read more about the Clean Up Provisioning option in Provisioning a Virtual EBS R12.2 Instance. Note that provisioning is still possible without this option specified, but you will need to manage the target dbTier's Oracle Inventory manually to ensure that conflicting entries do not cause provisions to fail.

The Delphix Engine's Oracle database requirements

The dbTier must meet the target requirements outlined in [Oracle support and requirements](#). These requirements are generic to all target Unix environments expected to host a virtual Oracle database.

Prepare the appsTier for provisioning

Delphix Engine's Unix environment requirements

The appsTier must meet the target requirements outlined in [Requirements for Unix environments](#). These requirements are generic to all target Unix environments added to the Delphix Engine.

`applmgr` user

The Delphix Engine must have access to an `applmgr` user on the appsTier.

- This user should be a member of the EBS `oinstall` group.
- This user will be given proper permissions to manage the appsTier.

## delphix\_os OS user account

In order to separate authentication and perform privileged operations with a non-privileged OS account, first create an OS user account (i.e. "delphix\_os") on the EBS DB Tier and appsTier node to be used as a target. This user is easily created by the createDelphixOSUser.sh (located below on this page) script.

- The primary OS group of the Delphix Engine software owner account's (i.e. delphix\_os) should be the same as the EBS Database/AppsTier software owner account (i.e. oravis or applmgr).
- Primary group = Oracle Install Group (typically oinstall), secondary group = OSDBA Group (typically dba). There are lots of cases where the OS group named dba fills this role, so be sure to check the group membership of the EBS Database and AppsTier software owner account.
- Please note, the non-privileged OS account must have the **same** group as assigned to EBS Database or appsTier privileged account (like oravis or applmgr).
- Ensure that "expect", "wget", and "lsf" utility exist on the remote host.

## Host requirements for multinode:

- The primary host and the secondary host user name and its UID, Group name and GID should be same to avoid the permission issue during the provisioning operation.
- Check the high and low privilege user id and GID in the primary and secondary node and change it accordingly using groupmod with the following commands:

```
$ id oravis
uid=509(oravis) gid=502(oinstall)
$ id delphix_os
uid=510(delphix_os) gid=502(oinstall)
Change the group id as root using,
...
...
# groupmod -g 502 oinstall
# usermod -g oinstall oravis
# usermod -g oinstall delphix_os
```

 Primary and secondary appstier host need to be configured with passwordless ssh if the target WLS password is going to be different from the source WLS password. Passwordless ssh configuration on the Appstier multinode host requirement is required for configuring WLS password different from source.

## Host requirements:

To accomplish necessary tasks on the EBS Database and appsTier target hosts, the Delphix OS user account (henceforth referred to as "delphix\_os") requires privilege elevation specifications. Ensure that "wget" and "lsf" utilities exist on the remote host.

Here is an example specification for the "sudo" privilege elevation utility, using the "visudo" to edit the "sudoers" configuration file. This specification makes the following assumptions:

- OS = Linux
  - OS account owning Oracle EBS Database Tier is named **oravis**
  - OS account owning Oracle EBS appsTier is named **applvis**
- OS = Solaris
  - OS account owning Oracle EBS Database Tier is named **oravis**
  - OS account owning Oracle EBS appsTier is named **oravis**

- EBS Database and appsTier system base directory is `/u01/oracle/VIS`. This can be prefixed before all the below-mentioned commands to ensure the same is being executed from relevant paths.

 The following sudoers entry is only for template purposes. Modify the path in the below sudoers entry with the appropriate binary paths of your environment.

### Sudoers entry for Linux

Entries required for provisioning via low privileged user (delphix\_os):

EBS DB Tier

```
Defaults:delphix_os !requiretty

### oralnst.loc

An oralnst.loc file must exist on every appsTier node prior to provisioning. This file will specify where the oralInventory directories live or where they should be created if they do not already exist.

The oralnst.loc file is typically located at `/etc/oraInst.loc` on Linux or `/var/opt/oracle/oraInst.loc` on Solaris. Ensure that the oralInventory to which this file points is writable by the `applmgr` user or application tier OS user.

If you are provisioning a single-node appsTier,

- [Required] The global inventory/central inventory(oralInventory) for each node should be on a local file system other than Delphix mount base path.

If you are provisioning a multi-node appsTier,

- The following recommendations are mandatory;
  - While configuring SHARED APPL\_TOP application, Delphix expects the oralInventory directory path should be beneath the Delphix mount base path.
  - The `inventory_loc` variable defined in file `/etc/oraInst.loc` on all application servers should point to same shared oralInventory directory location on shared Delphix mount base path.
  - The Delphix Engine's cloning workflow requires that all nodes in the appsTier have access to the shared oralInventory directories via Delphix-provided storage.
- [Required] The Delphix Engine's automation requires that all nodes in the appsTier have access to the oralInventory directories via Delphix-provided storage.

**i** Objective of placing oralInventory on Shared Delphix mount storage  
While configuring shared APPL\_TOP application, instead of storing oralInventory on the local directory of each server, all application servers should point to the same oralInventory directory on shared Delphix mount storage, so that you need to patch only on a single server and the oralInventory gets in-sync for all application servers thus preventing the oralInventory of remaining servers becoming invalid.

**=** Details can be found in **Sharing The Application Tier File System in Oracle E-Business Suite Release 12 (Doc ID 384248.1)** found at <https://support.oracle.com> . You can also consult Oracle EBS documentation for more information about where to place this file on your appsTier and what this file should contain.

### Clean up before provisioning option

If you plan to utilize the Cleanup Before Provision option available during appsTier provisioning, the Delphix Engine requires the Tools Oracle Home to be patched with Oracle Universal Installer (OUI) version 10.2 or above. You can read more about this provisioning option in Provisioning a Virtual EBS R12.2 Instance. Note that provisioning is still possible without this option specified, but you will need to manage the target appTier's Oracle Inventory manually to ensure that conflicting entries do not cause provisions to fail.

## Provisioning a virtual EBS R12.2 instance

This topic describes the process of provisioning a virtual EBS R12.2 instance.

- Maintain the integrity in names(CDB name, PDB name, DB hostname, /etc/hosts file format nomenclature). During dbTechStack, vPDB or vDB provisioning, maintain the same lower case and use the same name vPDB during virtual Appstier provision as well. There is no restriction on using UPPER or LOWER case characters. However, it is recommended to maintain consistency.

### Prerequisites

- You must have already linked a source instance of EBS R12.2. For more information, see [Linking a source EBS R12.2 instance](#)
- Prepare your target EBS R12.2 environments for provisioning by following the outline in [Preparing target EBS R12.2 environments for provisioning](#)

#### i **Snapshot coordination**

Changes applied to EBS and picked up only in certain dSource snapshots may make certain combinations of snapshots across the appsTier and dbTier incompatible. When provisioning, refreshing or rewinding a virtual EBS instance, be sure the points in time you select for each dataset are compatible with each other.

- The source DB host may have multiple DATA\_TOPs but the target DB host will be provisioned with a single DATA\_TOP that resides on the target Mount Base path provided during the database provisioning.

### Provisioning the EBS dbTechStack

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dbTechStack dSource**.
5. Click the **TimeFlow** tab.
6. Select a dSource **snapshot**.
7. Click **Provision**.  
The **Provision VDB** wizard will open.
8. Select an **Environment**.  
This environment will host the virtual dbTechStack and be used to execute hook operations specified in step 15 in the **s**section.
9. Select **E-Business Suite R12.2 dbTechStack** from the **Installation** dropdown.
10. Select an **Environment User**.
11. This user should be the `oracle` user-outlined in [Preparing target EBS R12.2 environments for provisioning](#)
12. Enter a **Mount Path** for the virtual dbTechStack files.
13. Enter the **EBS-specific parameters** for the virtual dbTechStack. A subset of these parameters is discussed in more detail below.
  - a. The **Privileged OS Account (Optional)** field should contain the high privileged user when the low privileged user is being used for provisioning.
  - b. The **Target APPS Password** is the new apps password that is required to configure virtual dbTechStack. This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone` process.

- c. Provide source oracle home directory name relative to Oracle base installation directory that was provided during linking of dbTechStack in Oracle Home input field.
- d. Ensure that the **Target DB Hostname** value is the short hostname, not the fully-qualified hostname.
- e. The **Target DB/CDB SID** is the new database SID (CDB SID in case of 19c) that is required to configure virtual dbTechStack.
- f. The **Target PDB Name** field is added for the pluggable database to be configured for Oracle 19c database. Please leave this field empty when using Oracle 11g/12c database.
- g. Provide **Target utl\_file\_dir** , the default value for this field will be “/var/tmp”. The **utl\_file\_dir** initialization parameter is deprecated in Oracle Database 12c Release 2 (12.2.0.1), and maybe unsupported in a future release.
- h. Provide **DISPLAY Variable**, the default value is hostname:0.0
- i. [Optional] Provide the **Custom Database Port Number** on which database listener must run.
  - Info:**
    - i. Enter a numeric port value in this field only if you want to use DB port customisation. Leaving this field blank automatically uses the default port based on port pool. The custom database port number is applicable only for Oracle 19c database.
    - ii. To run the dbTechStack and listener on custom DB port, it is recommended to provide **Target Port Pool** value either as default or 0; also the **Target Port Pool** value in dbTechStack is not related with **Run/Patch Edition Port Pool** value in Appstier.
- j. Provide **Target Port Pool**, please provide a port pool that is available. By default, the value is 1. The range for this value is 0 to 99.
- k. Enable the **Disable RAC** option if you want to permit the Delphix Engine to automatically disable the RAC option for the binaries when applicable. This option is necessary if provisioning from a dSource with RAC dbTier because the binaries are relinked with the `rac_on` option even after running `adcfgclone` . If the source binaries already have the RAC option disabled (also the case for SI dbTier), the Delphix Engine ignores this option.
- l. Enable the **Cleanup Before Provision** option if you want to permit the Delphix Engine to automatically clean up stale EBS configuration during a refresh. This option is recommended, but only available if your Oracle Home is patched with Oracle Universal Installer (OUI) version 10.2 or above.
  - i. With this option enabled, the Delphix Engine will inspect the target environment's oraInventory prior to refreshing this virtual dbTechStack. If any Oracle Homes are already registered within the specified **Mount Path**, the Delphix Engine will detach them from the inventory prior to running `adcfgclone`. These homes must be detached prior to running post-clone configuration. If they are not detached, `adcfgclone` will fail, citing conflicting oraInventory entries as an issue.
  - ii. Without this option enabled, Oracle Homes that conflict with the specified **Mount Path** will be reported in an error instead of automatically detached. For refresh to succeed, you must manually detach conflicting Oracle Homes prior to refresh.
- m. Provide **Oracle OS User** and **Group**, it's optional.

- Summary

### Target Configuration

Configure the target environment.

Mount Path \*

Path where the data will be mounted

Privileged OS Account (Optional)

This privileged unix username will be used to provision EBS dbTechStack. The privileged unix username should begin with a lower case letter or an underscore, followed by lower case letters, digits, underscores, or dashes. They can end with a dollar sign. Leave this field blank if you do not want to use privilege elevation.

**Target APPS Password**

This will be used to reconfigure the target application once the database is provisioned.

Username and Password ▼

User name

Password \*

Oracle Home \*

Path where ORACLE\_HOME will be relative to where the application data is being mounted.

Target DB Hostname \*

Target system database (short) hostname to pass to addtgsone.

Target DB-CDB SID \*

The new SID for the database (or CDB name in case of 19c DB) that will be provisioned.

Target POB Name

- Summary

TGTCDB

The new SID for the database (or CDB name in case of 19c DB) that will be provisioned.

Target POB Name

The name of POB that will be provisioned if using a 19c DB.

Target ut\_file\_dir \*

The new ut\_file\_dir (Absolute Path).

DISPLAY Variable \*

The value for the DISPLAY variable, for example 'hostname.0.0'.

Custom Database port number

Port number on which the database listener must run. Provide this value only if DB port customisation is required. Leave this field blank if you wish to use the default port based on port pool. Note: This is available only for 19c DB.

Target Port Pool

The new port pool for this environment. Should be between 0 and 99.

**Disable RAC option \***

Allow Delphix to automatically disable RAC option for the binaries if applicable. If the source binaries already have the RAC option disabled, this option is ignored.

**Cleanup Before Provision**

Allow Delphix to automatically perform necessary cleanup of stale EBS configuration prior to running addtgsone.

Oracle OS User

The Oracle OS user on the target environment.

Oracle OS Group

The Oracle OS group on the target environment.

Cancel Back Next Submit

14. Click **Next**.
15. Enter a **VDB Name**.
16. Select a **Target Group** for the VDB.  
If necessary, click the green **Plus** icon to add a new group.
17. Select a **Snapshot Policy** for the VDB.  
If necessary, click the **Plus** icon to create a new policy.  
**Warning:** Snapshot conflicts When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots.  
To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more.
18. Click **Next**.
19. Enter any **custom hook operations** that are needed to help correctly manage the virtual dbTechStack files.  
For more information about these hooks, when they are run, and how operations are written.

The Configure Clone hook will be run after the `adcfgclone.pl` tool has both mounted and configured the dbTechStack.

20. Click **Next**.
21. Click **Submit**.

When provisioning starts, you can review the progress of the job in the **Datasets** panel, or in the **Job History** panel of the **Dashboard**. When provisioning is complete, the dbTechStack VDB will be included in the group you designated and listed in the **Datasets** panel. If you select the dbTechStack VDB in the **Datasets** panel and click the **Configuration** tab, you can view information about the virtual files and its Data Management settings.

For tips on monitoring the progress of dbTechStack provisioning, see [Monitoring EBS R12.2 dbTechStack Provisioning Progress](#)

### Provisioning the Oracle 19C database

1. Refresh the Target DB environment from **Manage > Environments** so that the Listener brought up during dbTechStack provision gets discovered and the Installation Home to be listed in dropdown during Database provision. If Target DB environment is not refreshed, you will see `This environment has no compatible Oracle Installation Homes` in the Installation Home dropdown in the **Database provision**.
2. Provision the EBS database to the target dbTier environment by following the steps outlined in [Provisioning an Oracle VDB](#). For Oracle EBS database for 19c MT, provision the database by following the steps outlined in [Provisioning an Oracle Virtual Pluggable Database \(vPDB\)](#)  
Note: When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots.  
To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more.
3. Select the correct **Installation Home**.  
This should be the virtual dbTechStack you just added to the Delphix Engine.
4. Select an Environment User.
5. This user should be the oracle user-outlined in Preparing Target EBS R12.2 Environments for Provisioning.
6. For the **Container Database** option, select the checkbox next to **Create a New Container Database**, and click **Next**.
7. Select a Target Group for the VDB.
8. In the vPDB **Configuration** section, provide the Target PDB name given during dbTechStack provision in the **Oracle Pluggable Database Name** field and provide any unique user-defined name in **vPDB Name** to be displayed in the Delphix Engine.
9. In vCDB **CONFIGURATION** section, provide the Target DB/CDB SID name given during dbTechStack provision in the **Database Name** field and SID and provide any unique user-defined name in the **vCDB Name** and **Database Unique Name** field, and click **Next**.
10. Click **Advanced**.
11. Select the correct **Oracle Node Listeners** value.  
This should be the listener corresponding to the virtual dbTechStack you just added to the Delphix Engine.
12. Add the EBS R12.2 dbTier environment file as a **Custom Environment Variables** entry.
13. This file can be specified as an Environment File with Path Parameters of `$ORACLE_HOME/`  
`<CONTEXT_NAME>` .

Replace `<CONTEXT_NAME>` with the virtual EBS instance's context name. The Delphix Engine will expand the `$ORACLE_HOME` variable at runtime.

For more information, see [Customizing Oracle VDB environment variables](#)

**Note:** To complete the DB Provisioning operation, you must provide content to configure clones and pre-snapshot hooks. You must either follow step 14 to use the hooks utility feature OR proceed with the conventional way by following steps 15-21.

14. To complete the DB Provisioning operation, you must provide content to configure clones and pre-snapshot hooks. The following are the content for both the hooks:

- a. Configure Clone hook will be `<DBTechStack Mount point>/hooksutil/hooksrunner --operation configure`. You must set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password.
- b. Pre-Snapshot hook: `<DBTechStack Mount point>/hooksutil/hooksrunner --operation pre-snapshot`. You must set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password. In case the apps password change is required in target VDB, you can set hook environment variables `DLPX_TARGET_APPS_PASSWORD` and `DLPX_SYS_PASSWORD` for providing the target apps schema and system schema passwords.

**Note:**

For versions 19.3 or later, follow the below guidelines if you see any of the following error:

- i. ORA-01017: invalid username/password logon denied
- ii. ORA-28040 During cloning: No Matching Authentication Protocol

EBS application database user accounts created in the earlier release uses a case-insensitive password version from an earlier release authentication protocol, such as the 10G password version. If your release user account passwords have not been reset and the following conditions persists, then take the action as described below:

On source, the database server has been configured with `SEC_CASE_SENSITIVE_LOGON` set to `FALSE`, so that it can only authenticate users who have a 10G case-insensitive password version. Then, on target container VDB, it becomes necessary to set the `SEC_CASE_SENSITIVE_LOGON` to `FALSE`, to make authentication of users successful.

To take advantage of the password protections introduced in Oracle Database 19c, users must change their passwords.

Occasionally, it is necessary to restart the database to resolve connectivity to the database. This is atypical but may be necessary.

To set-up target:

On target container database, run the following command:

```
alter system set SEC_CASE_SENSITIVE_LOGON=FALSE scope=both;
```

15. Add a **Run Bash Shell Command** operation to the Configure Clone hook to ensure that `adcfgclone` is run against the newly provisioned database for a **high privileged user**, as shown in the script below.

**Note:** You can pass the credentials securely to Hook Operations by setting up the base variables. See [Passing credentials securely to hook operations](#) for more details.

**Note:** You must set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password. In case the apps password change is required in target VDB, you can set hook environment variables `DLPX_TARGET_APPS_PASSWORD` and `DLPX_SYS_PASSWORD` for providing the target apps schema and system schema passwords.

Configure clone first hook for a 19c multi-tenant high privileged user

```
#!/usr/bin/env bash
#
# Copyright (c) 2022 by Delphix. All rights reserved.
#
# shellcheck source=/dev/null
# NOTE: Ensure the below environment variables will be set up correctly by the
# shell. If not, hardcode or generate the values below.
```

```

HOSTNAME=$(uname -n | cut -d '.' -f1)
CONTEXT_NAME=${DELPHIX_PDB_NAME}_${HOSTNAME}
APPS_PASSWD=${DLPX_SOURCE_APPS_PASSWORD_PASSWORD}
. "${ORACLE_HOME}/${ORACLE_SID}_${HOSTNAME}.env";
# Check for local_listener parameter is set for PDB, otherwise set it
# appropriately
check_value=$(sqlplus -s "/" as sysdba" <<EOF
alter session set container="${DELPHIX_PDB_NAME}";
show parameter local_listener;
EOF
)
local_listener=$(echo "$check_value" | awk '{print $11}')
value=("${local_listener//:/ }")
host="${value[0]}"
port="${value[1]}"
curr_port=$(grep PORT < "${ORACLE_HOME}/network/admin/listener.ora" | awk
'{print $9}' | sed 's/)//g')
if [[ $port != "$curr_port" || $host != "${HOSTNAME}" ]]; then
sqlplus -s "/" as sysdba" <<EOF
alter session set container="${DELPHIX_PDB_NAME}";
alter system set local_listener='${HOSTNAME}:${curr_port}';
alter system register;
EOF
fi

#For compatibility with 6.0.16.0 Delphix engine version
. ${ORACLE_HOME}/${ORACLE_SID}_${HOSTNAME}.env; sqlplus -s "/" as sysdba" <<EOF
shutdown immediate;
startup;

perl "${ORACLE_HOME}/appsutil/clone/bin/adcfgclone.pl" dbconfig "$
${ORACLE_HOME}/appsutil/${CONTEXT_NAME}.xml" <<EOF # noqa
${APPS_PASSWD}
EOF

```

16. Configure Clone hook to ensure that `adcfgclone` is run against the newly provisioned database for a **low privileged user**, as shown in the script below.

**Note:**

Customers have to identify the `DLPX_DB_EXEC_SCRIPT` value from their remote environment, this would always be inside the toolkit directory provided while adding the environment on Delphix Engine. Configure clone first hook for a 19c multi-tenant low privileged user

```

#!/usr/bin/env bash
#

```

```

# Copyright (c) 2022 by Delphix. All rights reserved.
#
# shellcheck source=/dev/null
# NOTE: Ensure the below environment variables will be set up correctly by the
# shell. If not, hardcode or generate the values below.
DLPX_DB_EXEC_SCRIPT="

```

```

"${DLPX_DB_EXEC_SCRIPT}" -u"${DLPX_PRIV_USER}" ". ${ORACLE_HOME}/${ORACLE_SID}
_${HOSTNAME}.env; sqlplus \"/ as sysdba\" <<-EOF
@${ORACLE_HOME}/appsutil/install/${CONTEXT_NAME}/adupdlib.sql so
EOF
"
"${DLPX_DB_EXEC_SCRIPT}" -u"${DLPX_PRIV_USER}" ". ${ORACLE_HOME}/$
{CONTEXT_NAME}.env; perl ${ORACLE_HOME}/appsutil/clone/bin/adcfgclone.pl
dbconfig ${ORACLE_HOME}/appsutil/${CONTEXT_NAME}.xml <<-EOF1
${APPS_PASSWD}
EOF1
"

```

17. For the EBS database Oracle 12.2, add a **Run Bash Shell Command** operation to the Configure Clone hook to ensure that `sqlnet.ora` or `sqlnet_ifile.ora` specify a value for `SQLNET.ALLOWED_LOGON_VERSION_SERVER` for a **high privileged user**, as shown in the script below.

This requirement is outlined in **Cloning Oracle E-Business Suite Release 12.2 with Rapid Clone (Doc ID 1383621.1)** found at <http://docs.oracle.com>

18. When prompted, if your environment is on R12.TXK.C.Delta.13 or later, enter the password for the EBS\_SYSTEM user, if your environment is on R12.TXK.C.Delta.12 or earlier, enter the password for the SYSTEM user, or if your source EBS setup is running on AD-TXK Delta 13 then you need to supply the EBS\_SYSTEM schema password in the below second hook script.

This requirement is outlined in the FAQ: Oracle E-Business Suite and System Schema Migration (DocID 2758999.1) Using UTL\_FILE\_DIR or Database Directories for PL/SQL File I/O in Oracle E-Business Suite Releases 12.1 and 12.2 (DocID 2525754.1) found at <http://docs.oracle.com>

Configure clone second hook for a 19c multi-tenant high privileged user

```

#!/usr/bin/env bash
#
# Copyright (c) 2022 by Delphix. All rights reserved.
#
# shellcheck source=/dev/null
# Set the target UTL_FILE_DIR values in the Oracle 19c database in the below
# variable UTL_FILE_DIR_PATH separated by commas
# Example UTL_FILE_DIR_PATH=/u01/oracle/VIS/temp/VISPDB,\
# /u01/oracle/VIS/19.3.0/appsutil/outbound/UTL,/u01/tmp

# UTL_FILE_DIR_PATH=<provide utl_file_dir locations separated by commas>
# If your environment is on R12.TXK.C.Delta.13 or later, enter the password
# for the EBS_SYSTEM user. If your environment is on R12.TXK.C.Delta.12 or
# earlier, enter the password for the SYSTEM user.

### Provisioning the Oracle 12C database

1. Refresh the Target DB environment from **Manage > Environments** so that the Listener brought up during dbTechStack provision gets discovered and the Installation Home to be listed in dropdown during Database provision. If Target DB environment is not refreshed, you will see `This environment has no compatible Oracle Installation Homes` in the Installation Home dropdown in the **Database provision**.
2. Provision the EBS database to the target dbTier environment by following the steps outlined in [Provisioning an Oracle VDB](#). For Oracle EBS database for 19c MT, provision the database by following the steps outlined in [Provisioning an Oracle Virtual Pluggable Database \(vPDB\)](#)  
**Note:** When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots.  
To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more.
3. Select the correct **Installation Home**.  
This should be the virtual dbTechStack you just added to the Delphix Engine.
4. Select an Environment User.
5. This user should be the oracle user-outlined in Preparing Target EBS R12.2 Environments for Provisioning.
6. Select a Target Group for the VDB.
7. In the VDB **Configuration** section, provide Target DB/CDB SID name provided during dbTechStack provisioning in the **Oracle Database Name** and **Oracle SID** field. Provide any unique user-defined name in **VDB Name** and **Oracle Database Unique Name** and click **Next**.
8. Click **Advanced**.
9. Select the correct **Oracle Node Listeners** value.  
This should be the listener corresponding to the virtual dbTechStack you just added to the Delphix Engine.
10. Add the EBS R12.2 dbTier environment file as a **Custom Environment Variables** entry.
11. This file can be specified as an Environment File with Path Parameters of  `${ORACLE_HOME}/<CONTEXT_NAME> .`

Replace `<CONTEXT_NAME>` with the virtual EBS instance's context name. The Delphix Engine will expand the `$ORACLE_HOME` variable at runtime.

For more information, see [Customizing Oracle VDB Environment Variables](#). **Note:** To complete the DB Provisioning operation, you must provide content to configure clones and pre-snapshot hooks. You must either follow step 12 to use the hooks utility feature OR proceed with the conventional way by following steps 13-20.

12. To complete the DB Provisioning operation, you must provide content to configure clones and pre-snapshot hooks. The following are the content for both the hooks:
  - a. Configure Clone hook will be `<DBTechStack Mount point>/hooksutil/hooksrunner --operation configure`. You can set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password. In case, you are not sure about the source apps schema password, then you should skip the entire step 12.
  - b. Pre-Snapshot hook: `<DBTechStack Mount point>/hooksutil/hooksrunner --operation pre-snapshot`. You can set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password. In case of apps password change in target VDB, you can set hook environment variables `DLPX_TARGET_APPS_PASSWORD` and `DLPX_SYS_PASSWORD` for providing the target apps schema and system schema passwords.
13. Add a **Run Bash Shell Command** operation to the Configure Clone hook to ensure that `adcfgclone` is run against the newly provisioned database for a **high privileged user**, as shown in the script below. **Note:** You must set a hooks environment variable `DLPX_SOURCE_APPS_PASSWORD` for providing the source apps schema password. In case the apps password change is required in target VDB, you can set hook environment variables `DLPX_TARGET_APPS_PASSWORD` and `DLPX_SYS_PASSWORD` for providing the target apps schema and system schema passwords. Configure clone first hook for a high privileged user

```
#!/usr/bin/env bash
#
# Copyright (c) 2022 by Delphix. All rights reserved.
#
# shellcheck source=/dev/null
# NOTE: Ensure the below environment variables will be set up correctly by
# the shell. If not, hardcode or generate the values below.
HOSTNAME=$(uname -n | cut -d '.' -f1)
CONTEXT_NAME=${ORACLE_SID}_${HOSTNAME}
APPS_PASSWD=${DLPX_SOURCE_APPS_PASSWORD}

. "${ORACLE_HOME}/${CONTEXT_NAME}.env";
# Check for local_listener parameter is set for SID, otherwise set it
# appropriately
check_value=$(sqlplus -s "/" as sysdba" <<EOF
show parameter local_listener;
EOF
)
local_listener=$(echo "$check_value" | awk '{print $11}')
value=("${local_listener}://")
```

```

host="${value[0]}"
port="${value[1]}"
curr_port=$(grep PORT < "${TNS_ADMIN}/listener.ora" | awk '{print $9}' | sed
's/)//g')

if [[ $port != "$curr_port" || $host != "${HOSTNAME}" ]]; then
sqlplus -s "/ as sysdba" <<EOF
alter system set local_listener='${HOSTNAME}:${curr_port}';
alter system register;
EOF
fi

sqlplus "/ as sysdba" <<EOF
@${ORACLE_HOME}/appsutil/install/${CONTEXT_NAME}/adupplib.sql so
EOF

perl "${ORACLE_HOME}/appsutil/clone/bin/adcfgclone.pl" dbconfig "$
{ORACLE_HOME}/appsutil/${CONTEXT_NAME}.xml" <<EOF
${APPS_PASSWD}
EOF

```

14. Configure Clone hook to ensure that `adcfgclone` is run against the newly provisioned database for a **low privileged user**, as shown in the script below. Customers have to identify the `DLPX_DB_EXEC_SCRIPT` value from their remote environment, this would always be inside the toolkit directory provided while adding the environment on Delphix Engine. Configure clone first hook for a low privileged user

```

#!/usr/bin/env bash
#
# Copyright (c) 2022 by Delphix. All rights reserved.
#
# shellcheck source=/dev/null
# NOTE: Ensure the below environment variables will be set up correctly by the
# shell. If not, hardcode or generate the values below.

DLPX_DB_EXEC_SCRIPT=""
DLPX_PRIV_USER=oravis
APPS_PASSWD=${DLPX_SOURCE_APPS_PASSWORD_PASSWORD}
HOSTNAME=$(uname -n | cut -d '.' -f1)
CONTEXT_NAME=${ORACLE_SID}_${HOSTNAME}

. "${ORACLE_HOME}/${CONTEXT_NAME}.env";
# Check for local_listener parameter is set for SID, otherwise set it
# appropriately
check_value=$(sqlplus -s "/ as sysdba" <<EOF
show parameter local_listener;
EOF
)
local_listener=$(echo "$check_value" | awk '{print $11}')
value=("${local_listener//:/ }")
host="${value[0]}"

```

```

port="${value[1]}"
curr_port=$(grep PORT < "${TNS_ADMIN}/listener.ora" | awk '{print $9}' | sed
's/)//g')

if [[ $port != "$curr_port" || $host != "${HOSTNAME}" ]]; then
sqlplus -s "/ as sysdba" <<EOF
alter system set local_listener='${HOSTNAME}:${curr_port}';
alter system register;
EOF
fi

"${DLPX_DB_EXEC_SCRIPT}" -u"${DLPX_PRIV_USER}" ". ${ORACLE_HOME}/$
{CONTEXT_NAME}.env; sqlplus \"/ as sysdba\" <<-EOF
@${ORACLE_HOME}/appsutil/install/${CONTEXT_NAME}/adupplib.sql so
EOF
"

"${DLPX_DB_EXEC_SCRIPT}" -u"${DLPX_PRIV_USER}" ". ${ORACLE_HOME}/$
{CONTEXT_NAME}.env; perl ${ORACLE_HOME}/appsutil/clone/bin/adcfgclone.pl
dbconfig ${ORACLE_HOME}/appsutil/${CONTEXT_NAME}.xml <<-EOF1
${APPS_PASSWD}
EOF1
"

```

15. For the EBS database Oracle 12.2, add a **Run Bash Shell Command** operation to the Configure Clone hook to ensure that `sqlnet.ora` or `sqlnet_ifile.ora` specify a value for `SQLNET.ALLOWED_LOGON_VERSION_SERVER` for a **high privileged user**, as shown in the script below. This requirement is outlined in **Cloning Oracle E-Business Suite Release 12.2 with Rapid Clone (Doc ID 1383621.1)** found at <http://docs.oracle.com>
- Configure clone second hook for a high privileged user

```

#!/usr/bin/env bash

`\${ORACLE\_SID}\_source\_apps\_file.txt` will be created automatically inside the `/var/tmp/` location of the target database host once the DBTechStack provisioning is completed.

### Provisioning the EBS appsTier

1. Login to the **Delphix Management** application using **Admin** credentials.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier dSource**.
5. Select a dSource **snapshot**.

All snapshots will have staged configuration prepared by `adpreclone.pl` and any hook operations placed on the dSource.

6. Click **Provision**.  
The **Provision VDB** wizard will open.
7. Select an **Environment**.  
This environment will host the virtual appsTier and be used to execute hook operations specified in a few steps. This environment will also run the WebLogic Admin server (Web Administration service) for the virtual appsTier.  
If you are provisioning a multi-node appsTier, you will be able to specify additional environments to host the virtual appsTier in a few steps.
8. Select E-Business Suite R12.2 appsTier from the **Installation** dropdown.
9. Select an Environment User.  
This user should be the `app_lmgr` user-outlined in [Preparing Target EBS R12.2 Environments for Provisioning](#)
10. Enter a **Mount Path** for the virtual appsTier VDB. If you are provisioning a multi-node appsTier, this mount path will be used across all target environments.
11. Enter the **EBS-specific parameters** for the virtual appsTier. A subset of these parameters are discussed in more detail below.

- Target Environment
- Target Configuration
- Configuration
- Policies
- Masking
- Hooks
- Summary

### Target Configuration

Configure the target environment.

Mount Path \*

/U01/oracle/APPS

Path where the data will be mounted on

Privileged OS Account (Optional)

applmgr

This privileged unix username will be used to provision EBS appsTier. The unix privileged username should begin with a lower case letter or an underscore, followed by lower case letters, digits, underscores, or dashes. They can end with a dollar sign. Leave this field blank if you do not want to use privilege elevation.

*In case of low privilege user, mention OS user that should own appsTier binaries*

### Target APPS Password

The desired APPS password for the EBS instance. A password change will be performed if this password does not match that of the source EBS instance.

Username and Password

User name

apps

Password \*

\*\*\*\*

### Target Weblogic AdminServer Password

This will be used to reconfigure the target application once provisioned. A password change will be performed if this password does not match that of the source EBS instance. NOTE: This password MUST contain at least 1 alphabet and 1 non-alphabet and it MUST be at least 8 characters long.

Username and Password

User name

weblogic

Password \*

\*\*\*\*\*

Cancel Back Next Submit

- a. **Privileged OS Account (Optional)** field should contain high privileged user when low privileged user is being used for provisioning.
- b. The **Target APPS Password** is the new apps password that is required to configure and manage the virtual appsTier.  
This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone`, `adstrtal`, and `adstpall` processes.
- c. The **Weblogic AdminServer Password** is the new WebLogic password required to configure the virtual appsTier. A password change will be performed if this password does not match that of the source EBS instance. This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone`, `adstrtal`, and `adstpall` processes.
- d. The **SYSTEM Password** is required to configure the virtual appsTier with the new apps password. This password is not required if the Target Apps Password is the same as the source.
- e. Provide the Target Application hostname.
- f. The **Target DB/PDB SID** is the new database SID (PDB SID in case of 19c) that is required to configure and manage the virtual appsTier.
- g. Provide the Target DB server node hostname.
- h. Provide **Target DB Domain Name**, this will be provided to the `adcfgclone`.
- i. Delphix recommends specifying an **Instance Home Directory** under the **Mount Path** so that instance-specific EBS files live on Delphix-provided storage.

Provision Plugin-based VDB

- Target Environment
- Target Configuration**
- Configuration
- Policies
- Masking
- Hooks
- Summary

Target Application Hostname \*  
**ukapp99**

Target system application server (short) hostname to pass to adcfclone.

---

Target Application File System Owner (Optional)

The file system owner for applications on the target environment. This is an optional parameter which will be used if adcfclone requires it.

Target DB/PDB SID \*  
**TGTPDB**

The SID for target system database (or PDB Name in case of 19c DB).

Target DB Server Node \*  
**ukexadb01**

Target system database server (short) hostname to pass to adcfclone.

Target DB Domain Name \*  
**delphix.com**

Target system database domain name to pass to adcfclone.

Instance Home Directory (Absolute Path) \*  
**/u02/oracle/APPS**

Path where the INST\_TOP for this copy should be created from (Absolute Path).

**Services**

Root Service 🔴

Web Entry Point Services

Web Application Services

Batch Processing Services

Other Services

DISPLAY Variable \*  
**ukapp99:0.0**

The value for the DISPLAY variable, for example 'hostname:0.0'.

Enter the Instance Home Directory same as Delphix Base Mount Path

For example, if the provided **Mount Path** is `/u01/oracle/VIS` , then providing an **Instance Home Directory** of `/u01/oracle/VIS` would allow EBS to generate virtual application INST\_TOP in `/u01/oracle/VIS/fs1/inst/apps/<CONTEXT_NAME >` and `/u01/oracle/VIS/fs2/inst/apps/<CONTEXT_NAME >`.

- i. If you are provisioning a single-node appsTier, this recommendation is OPTIONAL; putting instance-specific EBS files on Delphix-provided storage merely eases the administration of the virtual EBS instance.
- ii. If you are provisioning a multi-node appsTier, this recommendation is REQUIRED; the Delphix Engine's automation requires that all nodes in the appsTier have access to instance-specific files via Delphix-provided storage.
- j. Ensure that the **Target Application Hostname** and **Target DB Server Node** values are the short hostnames, not the fully-qualified hostnames.
- k. Select **Services**, by default all the **Root, Web Entry Point, Web Application** and **Batch Processing** would be checked. In case you are using multinode environment and want to start a few services on a secondary node then this field is going to be very useful for you.
- l. Provide **DISPLAY Variable**, the default value is hostname:0.0
- m. [Optional] Provide the **Custom Database Port Number** on which database listener must run.  
**Note:** Enter the numeric port value in this field only if you want to use DB port customisation, and this value should match with the custom database port number given during the DBTechStack provisioning. Leaving this field blank automatically uses the default port based on port pool. The custom database port number is applicable only for Oracle 19c database.

- n. Provide **Target Run Edition Port Pool**, the value of this field should be 0 to 99. This should match with the port pool value given during the DBTechStack provisioning.
- o. Provide **Target Patch Edition Port Pool**, the value of this field should be 0 to 99. This value should be Target Run Edition Port Pool plus 1. For example, if Run Edition Port Pool is 9 then the value should be 10. **Note:** Target Apps server **RUN Edition Port Pool** value cannot be the same as **PATCH Edition Port Pool** value of source Apps server.

Provision Plugin-based VDB ✕

- Target Environment
- Target Configuration
- Configuration
- Policies
- Masking
- Hooks
- Summary

Custom Database port number

**34001**

Port number on which the database listener is running. Provide this value only if DB port customization was done during DBTechstack provisioning. Leave this field blank if you have used port pool values. Note: This is available only for 19c DB.

Target Run Edition Port Pool \*

**10**

The new Run Edition port pool for this environment. Should be between 0 and 99. Note: If Custom DB port is used, kindly provide port pool value different from source/primary.

Target Patch Edition Port Pool \*

**20**

The new Patch edition port pool for this environment. Should be between 0 and 99. Note: If Custom DB port is used, kindly provide port pool value different from source/primary.

EBS AppsTier Process Timeout (In minutes) \*

**10**

If this timeout value is exceeded while stopping application services during a stop or refresh operation any long-running appsTier processes will be terminated.

EBS AppsTier Provision/Refresh Timeout (In hours) \*

**8**

Timeout value, in hours. This value will control the timeout for appsTier file provision/refresh operation execution.

Java Color Scheme (Optional) \*

**Swan**

Choose any of the following colors (Swan, Blue, Khaki, Olive, Purple, Red, Teal, Titanium) to set Java Color Scheme for EBS appsTier Java based Forms interface.

Target System Proxy Hostname (Optional)

**proxyhost**

Enter a valid proxy hostname. This is an optional parameter which will be used if adcfclone requires it.

Target System Proxy Port (Optional)

**80**

Enter a valid proxy port. This is an optional parameter which will be used if adcfclone requires it.

**Cleanup Before Provision**

Allow Delphix to automatically perform necessary cleanup of stale EBS configuration prior to running adcfclone.

**Start Services After Provision**

Allow Delphix to start the services of EBS appsTier after provisioning.

Additional Nodes

+ Add

Cancel Back Next Submit

- p. The **EBS AppsTier Timeout** is required to terminate all the long-running appsTier processes which have exceeded the timeout value when stopping the applications as part of a refresh. This timeout will be calculated in minutes. For example, if set to 30, then we run adstpall at the start of the refresh, and if after 30 minutes the application has not stopped, then the processes will be terminated to allow the refresh to continue.
- q. The **EBS AppsTier Provision/Refresh Timeout** is required to terminate configure and cloning via `adcfclone` process which have exceeded the timeout as part of a provision/refresh. This timeout will be calculated in hours and the default value will be 8 hours. For example, if set to 9, then plugin will detect a timeout after 9 hours instead of getting in a hung state and UI error for the same will be prompted.
- r. The **Java Color Scheme** is an **optional** parameter and is used to change the JAVA color for provisioned Oracle EBS JAVA based form interface. Please choose any of the following colors (Swan, Blue, Khaki, Olive, Purple, Red, Teal, Titanium) to set Java Color Scheme for EBS appsTier java-based forms interface.
- s. Provide **Target System Proxy Hostname (Optional)**, This is an optional parameter that will be used if `adcfclone` requires it.
- t. Provide **Target System Proxy Port (Optional)**, This is an optional parameter that will be used if `adcfclone` requires it.
- u. Enable the **Cleanup Before Provision** option if you want to permit the Delphix Engine to automatically cleanup stale EBS configuration during a refresh. This option is recommended, but only available if your Oracle Home is patched with Oracle Universal Installer (OUI) version 10.2 or above.
  - i. With this option enabled, the Delphix Engine will inspect the target environment's oraInventory prior to refreshing this virtual appsTier. If any Oracle Homes are already registered within the specified **Mount Path**, the Delphix Engine will detach them from the inventory prior to running `adcfclone`. These homes must be detached prior to running

- post-clone configuration. If they are not detached, `adcfgclone` will fail, citing conflicting oraInventory entries as an issue. The Delphix Engine will also remove any conflicting INST\_TOP directories left on the environment. Non-conflicting INST\_TOP directories will not be modified.
- ii. Without this option enabled, Oracle Homes or INST\_TOP directories that conflict with the specified **Mount Path** or desired INST\_TOP location will be reported in errors instead of automatically cleaned up. For refresh to succeed, you must manually detach conflicting Oracle Homes and manually remove conflicting INST\_TOP directories prior to refresh.
  - v. Enable the **Start Services After Provision** option if you want to permit the Delphix Engine to automatically start the services for EBS appsTier after provisioning.
    - i. With this option enabled, the Delphix Engine will start all the services of EBS appsTier after provisioning.
    - ii. Without this option enabled, the Delphix Engine will **NOT** start the services of EBS appsTier after provisioning. This will allow customers to prevent EBS services from being started at the conclusion of provisioning or refreshing. That way, customers can perform post-clone processing automation using a configure-clone hook without having to stop services first.
  - w. If you are provisioning a multi-node appsTier, enter additional appsTier nodes as **Additional Nodes**.
    - i. Select the Environment for the secondary node.
    - ii. The **Environment User** for each node should be the `app1mgr` user-outlined in [Preparing Target EBS R12.2 Environments for Provisioning](#)
    - iii. Ensure that the **Hostname** value for each node is the short hostname, not the fully-qualified hostname.
    - iv. Provide DISPLAY Variable, the default value is hostname:0.0.
    - v. The **Mount Path** is not configurable for each node individually. The **Mount Path** provided for the primary environment will be used for each additional node.
12. Click **Next**.
  13. Enter a **VDB Name**.
  14. Select a **Target Group** for the VDB.  
If necessary, click the **Plus** icon to add a new group.
  15. Select a **Snapshot Policy** for the VDB.  
If necessary, click the **Plus** icon to create a new policy.
- Note:**  
When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots.  
To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more.  
Click **Next**.
16. Enter any **custom hook operations** that are needed to help correctly manage the virtual appsTier.  
The Configure Clone hook will be run after the `adcfgclone.pl` tool has both mounted and configured the appsTier.  
All hook operations run against the environment specified for provision. For a multi-node appsTier, hook operations never run against additional nodes specified.
  17. Click **Next**.
  18. Click **Submit**.  
**Info:** Post-clone configuration will fail if the appsTier cannot connect to the database. Ensure the target dbTier is accessible to the appsTier during the provisioning process. Ensure both the virtual database and database listener are running. **Note:** If your source setup is EBS ISG enabled, then during virtual AppsTier creation on the target server, perform post cloning steps as described in [Installing Oracle E-Business Suite Integrated SOA Gateway, Release 12.2](#) (Doc ID 1311068.1).  
When provisioning starts, you can review the progress of the job in the **Datasets** panel, or in the **Job History** panel of the **Dashboard**. When provisioning is complete, the appsTier VDB will be included in the group you

designated and listed in the **Datasets** panel. If you select the appsTier VDB in the **Datasets** panel and click the **Configuration** tab, you can view information about the virtual files and its Data Management settings.

19. For tips on monitoring the progress of appsTier provisioning, see [Monitoring EBS R12.2 appsTier Provisioning Progress](#)

Once all three EBS virtual datasets have been provisioned successfully, your virtual EBS instance should be running and accessible.

**i** **Rewind operation on snapshot**

Perform the rewind operation on the snapshot after Appstier provisioning in the following sequence.

1. Take a snapshot of the Database VDB after Appstier provision.
2. Stop the appsTier, DB, and dbTechStack one by one.
3. Rewind dbTechStack, DB, and appsTier one by one.

If the DB snapshot was taken before appsTier provisioning, rewinding the DB will cause loss of new data updated by appsTier during provisioning and the next operation of appsTier rewind will fail. So, to ensure that the Rewind operation of appsTier succeeds, take a snapshot of DB after Appstier provision.

### Registering the EBS dbTechStack

Register the freshly-provisioned dbTechStack with the Delphix Engine.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **target dbTier environment**.
5. Click the **Databases** tab.
6. Click the **Plus** icon next to **Add Dataset Home**.
7. Select **Oracle** as your **Dataset Home Type**.
8. Enter an **Installation Home**.

This path should be the value of `$ORACLE_HOME` on your target dbTier; this path will live under the mount path specified when you provisioned the virtual dbTechStack.

Commonly, this path looks like `/u01/oracle/VIS/11.2.0`.

9. Click the **checkmark** to save your dataset home.  
If necessary, scroll down the list of dataset homes to view and edit this dataset home.
10. Refresh the dbTier environment.  
Refreshing the environment will discover an EBS database listener and ensure it is available for selection when provisioning the EBS database.
  - a. Click the **Refresh** button in the top right-hand corner of the environment card.

## Monitoring EBS R12.2 appsTier provisioning progress

This topic describes how to monitor the progress of EBS R12.2 appsTier provisioning.

The Delphix Engine automates the configuration of the appsTier during provisioning. It spends the majority of provisioning time running RapidClone utilities such as `adcfgclone`. The Delphix Engine does not report the progress of RapidClone utilities through the progress of the **DB\_Provision** job. To track provisioning progress more accurately, Delphix recommends monitoring EBS log files generated on the target appsTier environment.

### Procedure

1. Connect to the target appsTier environment using SSH or an alternative utility.
2. Change directories to the `<INST_TOP>/admin/log/`.
  - Replace `<INST_TOP>` with the value of `INST_TOP` on the virtual EBS instance.
3. After `adcfgclone` has begun running, a file matching `ApplyAppsTier_*.log` will exist. Identify this log file and use `tail` or an equivalent utility to monitor it.

#### Leave the Mount Point Prior to Refresh

If provisioning fails, you will need to fix the cause of the failure and perform a refresh of the dataset before you can attempt configuration again. Prior to refreshing or disabling the dataset, be sure to change directories to a location outside of the mount path on the target environment. If you leave a shell session with a current working directory inside the mount path, the dataset will fail to unmount cleanly during a refresh or disable.

## Monitoring EBS R12.2 dbTechStack provisioning progress

This topic describes how to monitor the progress of EBS R12.2 dbTechStack provisioning.

The Delphix Engine automates the configuration of the dbTechStack during provisioning. It spends the majority of provisioning time running RapidClone utilities such as `adcfgclone`. The Delphix Engine does not report the progress of RapidClone utilities through the progress of the **DB\_Provision** job. To track provisioning progress more accurately, Delphix recommends monitoring EBS log files generated on the target dbTier environment.

### Procedure

1. Connect to the target dbTier environment using SSH or an alternative utility.
2. Change directories to the `<ORACLE_HOME>/appsutil/log/<CONTEXT_NAME>/`
  - Replace `<ORACLE_HOME>` with the path to the dbTechStack's Oracle Home. This path will be under the mount path specified during provisioning.
  - Replace `<CONTEXT_NAME>` with the virtual EBS instance's context name.
3. After `adcfgclone` has begun running, a file matching `ApplyDBTechStack_*.log` will exist. Identify this log file and use `tail` or an equivalent utility to monitor it.

#### **Leave the mount point prior to refresh**

If provisioning fails, you will need to fix the cause of the failure and perform a refresh of the dataset before you can attempt configuration again. Prior to refreshing or disabling the dataset, be sure to change directories to a location outside of the mount path on the target environment. If you leave a shell session with a current working directory inside the mount path, the dataset will fail to unmount cleanly during a refresh or disable.

## Linking & provisioning TDE Enabled (19c) Oracle EBS PDB

### Pre-requisites

#### 1. Oracle: Multi-Tenant TDE for VCDBs

Make sure to use transparent data encryption (TDE) with virtual container databases to secure data-at-rest. Existing TDE keys can be used or data can be rekeyed upon deployment. Automated KeyStore sanitization ensures production TDE keys are not shared with non-production environments. This workflow allows you to automate the Oracle data lifecycle end-to-end, which results in developer productivity enhancements.

2. For a cluster target, it is recommended to place auto-login keystore on the ACFS storage instead of the Delphix mounted storage.
3. The Oracle EBS database version must be 19c (12c, 11g is not supported).
4. With 7.0.0.0 release, existing dSources can now have encrypted system tablespaces, and thus the resulting vPDBs will also have encrypted system tablespaces. Plugin doesn't support encrypting an existing unencrypted vPDB - the encryption comes from the dSource.  
Prior to 6.0.15.0, If the source has encrypted system tablespaces(SYSTEM, SYSAUX, UNDOTBS\*), linking or ingestion of the source in Delphix Engine would fail.
5. Source database keystores must not be on ASM storage.
6. Only software keystores on the same host as the database files are supported. In particular, Oracle Key Vault is not supported.
7. The dSource from which the initial provision is done must be encrypted when it is linked. Existing dSources cannot be encrypted without unlinking and creating a new dSource.

#### Points to pay attention to:

- A CDB with one PDB (single tenant) is currently the only certified deployment for Oracle E-Business Suite with Database 19c.
- A CDB with multiple PDBs (multi-tenant) is not currently certified for Oracle E-Business Suite.
- A non-CDB architecture is not planned to be certified or supported for EBS with Database 19c.

### High-level steps:

1. Create virtual dbTechStack using plugin, Make sure to remember the names of CDB, PDB that end user input in Delphix Engine UI wizard, as same will be used during vCDB and vPDB
2. Refresh target host environment in DE UI
3. Copy source DB keystore (WALLET\_ROOT) files `cwallet.sso` , `ewallet.p12` to target server.
4. During VDB provision, use **Create a new container database option** on Delphix Engine UI to create vCDB & vPDB.
5. Create new EBS services in vPDB. To avoid confusion, delete the EBS services that have drifted downstream from dSource to target vPDB.
6. Create virtual AppsTier using EBS plugin.

### Overview

Provisioning a Virtual Pluggable Database (vPDB) first involves using the GUI or CLI to specify the vPDB parameters (such as the vPDB name and target container) along with the snapshot to provision from. Once the provisioning is started with these parameters, the Delphix Engine does the following:

1. Mounts the snapshot files on the target host.
2. Creates and opens (in mount mode) the auxiliary container database on the target host, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.

3. Completes recovery to bring the auxiliary container database into a consistent state.
4. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
5. Plugs the vPDB into the target database, and opens it in read-write mode for general use.

If the dSource is TDE-enabled, then Delphix Engine will need to perform the following additional operations to complete the provision of a TDE-enabled vPDB to a TDE-enabled target container.

1. Mounts the snapshot files on the target host.
2. Creates a keystore with the necessary keys to apply encrypted archived log files.
3. Creates and opens (in mount mode) the auxiliary container database on the target host, using the snapshot files. The auxiliary container database will have both the CDB and PDB data files from the dSource.
4. Completes recovery to bring the auxiliary container database into a consistent state.
5. Rotates the vPDB and auxiliary CDB master encryption keys by generating new keys that are unique to the vPDB / auxiliary CDB and not associated with the source PDB or CDB.
6. Exports only the newly generated keys to an exported keyfile to enable unplug.
7. Finalizes the state of the auxiliary database and unplugs the vPDB datafiles.
8. Imports the keys from the exported keyfile into the target keystore.
9. When provisioning to a vCDB target, converts the auxiliary CDB into the final vCDB and creates the vCDB keystore from the auxiliary CDB keystore.
10. Plugs the vPDB into the target database, and opens it in read-write mode for general use.

If the initial provision of a TDE-enabled vPDB to a vCDB has either failed or been cancelled before step 9, which creates the vCDB keystore, refreshing that vPDB will fail because there is no target keystore to merge into the auxiliary CDB keystore for use during recovery. In this case, it will be necessary to delete the failed/cancelled vPDB and provision again. This does not apply when provisioning to a linked target CDB, which will already have its own keystore configured.

The following diagram illustrates the provisioning steps.

At each stage of provisioning, the keys and exported keyfiles are always on user storage. The exported keyfile is located in the artifact directory, while the auxiliary and target keystores are in the auxiliary keystores directory. Both the artifact directory and auxiliary keystores directory are subdirectories of the TDE keystores root directory, which is either user specified, or if not specified defaults to the toolkit root directory. As for non-TDE-enabled vPDBs, the final vPDB (and vCDB, if applicable) is on Delphix Engine storage while the target linked CDB and its archive logs remain on user storage.

Provisioning a TDE-enabled vPDB

To initiate the provision, Delphix needs the following pieces of information, all of which can be specified in the GUI or CLI:

Parameter	Description	CLI Parameter	Required or not
Parent keystore path	Path to a keystore that contains the keys used to encrypt the dSource datafiles. This keystore must be located on the target system. It does not have to be in the location specified by <code>sqlnet.ora</code> or <code>wallet_root</code> , but can be for consistency. It cannot be located on an ASM filesystem. This parameter can be updated if the path is changed.	<code>source.parentTdeKeystorePath</code>	Yes

Parameter	Description	CLI Parameter	Required or not
Parent keystore password	Password for the parent keystore. This parameter can be updated if the password is changed.	source.tdeExportedKeyFileSecret	Yes
Exported keyfile secret	When exporting keys to a keyfile from a keystore, Oracle requires a password to be set. Once specified, this cannot be changed for the life of the vPDB.	source.tdeExportedKeyFileSecret	Yes
Target keystore password	Password for the target keystore. This parameter can be updated if the password is changed.	sourceconfig.tdeKeystorePassword	Yes
Keystores root directory path	Path to a directory on the target host under which all Delphix related TDE artifacts will be created. This includes keystores used by the auxiliary CDB during provisioning and the artifact directories for TDE-enabled vPDBs.	host.oracleParameters.tdeKeystoreRootPath	Yes for cluster targets, optional for single instance targets
Target vCDB TDE Keystore Location	Path of the location at which Delphix Engine will create the keystore for vCDB provision jobs. This keystore must be located on the target system. For Oracle 12.2 the path must match what is specified by sqlnet.ora. For higher versions, Delphix Engine will set the wallet_root parameter to the provided location. This parameter must be updated if the keystore location is changed or else future Delphix Engine operations may fail.	source.targetVcdbTdeKeystorePath	Yes for vCDB targets. Not applicable to linked CDB targets
Target vCDB TDE Keystore Password	Password for the vCDB keystore. This parameter can be updated if the password is changed.	virtualCdb.sourceConfig.tdeKeystorePassword	Yes for vCDB targets. Not applicable to linked CDB targets

#### Linking of source TDE PDB

1. Login to the **Delphix Management** application.
2. Go to **Manage > Environments**.
3. Click the **Details** tab.
4. Click on the edit icon next to **ATTRIBUTES**.

5. In the **TDE Keystores Root field**, enter the path for the TDE Keystores root path.
6. Click the tick mark button to save the configuration.

#### Adding or editing the TDE keystores root directory path

The TDE Keystores root directory path is specified on the **Details** tab under **Environments**. To edit the path, do the following:

1. Login to the **Delphix Management** application.
2. Go to **Manage > Environments**.
3. Click the **Details** tab of the environment.
4. Click on the edit icon next to **ATTRIBUTES** to set or update attributes, including the Keystores root directory path.

### Adding or editing the target keystore password

The target Keystore password is specified on the **Databases** tab under **Environments**. To add or edit the target Keystore password, do the following:

1. Login to the **Delphix Management** application.
2. Go to **Manage > Environments**.
3. Click the **Databases** tab of the Environment.
4. Click on the edit icon next to **TDE Keystore Password** to set or update the password.

5. Click on **Add source**. The **Add dSource** wizard displays.
6. Fill in the details and click **Submit**.

For more information, see [Linking an Oracle pluggable database](#) & [Linking data sources with Oracle](#)

After you have successfully linked the source PDB:

- Create a dbTechStack on the target server using the plugin.
- Refresh the target host environment in the Delphix Engine UI.
- Copy the source DB keystore (WALLET\_ROOT) files `cwallet.sso` , `ewallet.p12` to target server and mention that location in **Parent Database TDE Keystore Location**.

```

On Source CDB, run below query to get WALLET_ROOT(files cwallet.sso,
ewallet.p12) location -
select wrl_parameter from v$encryption_wallet;
WRL_PARAMETER
-----
/home/oravis/wallet/tde/
    
```

It is mandatory to copy the `ewallet.p12` file from the source to the target server for the target container database to use it. No exporting of keys needed, this is done by the Delphix engine itself using the path and secrets provided in the configuration. On target server, `cwallet.sso` , `ewallet.p12` files should be owned by ORACLE\_HOME installation owner.

The **Parent Database TDE keystore Location** is the location of the keystore for the dSource, which can be the actual location if it's a provision back to the source, or else it needs to be copied to the target. the parent keystore password is the password for the dSource keystore. You can decide the **TDE Secret for Exported Keys**, which is a mandatory input and secret can be anything, it is used when exporting and importing the encryption keys.

Once a TDE-enabled vPDB is provisioned, it can be used the same as a non-TDE-enabled vPDB within Delphix, with the exception of **migrate**. There are few caveats:

- A refresh operation will use the parent keystore for the recovery. If the dSource is rekeyed then the user will need to update the parent keystore with the new keys. Similarly, if the location or password to the parent keystore has changed then they should be updated before the refresh.
- A rewind operation will use the target keystore for the recovery. If the vPDB is rekeyed after it is provisioned, then the rekey will update the target keystore, so it does not need to be updated in Delphix.
- For a single vPDB in a vCDB, if the vCDB keystore location is changed, the new path must be updated in Delphix before refresh or rewind.
- Each disable operation will result in the keys being exported to an exported keyfile in the artifact directory, to be used for a subsequent enable. Refresh and rewind operations will first disable the existing vPDB, so those will also result in a new exported keyfile in the artifact directory.
- Provisioning a second-generation vPDB (vvPDB) from a TDE-enabled vPDB is done in the same manner as a first-generation vPDB, by specifying the TDE parameters during provision. The current keystore for the vPDB can be specified as the parent keystore.

### TDE keystores root and artifact directory

The artifact directory stores the exported keyfiles used during the workflows for TDE-enabled vPDBs. It is located under the keystores root, in the directory `oracle_tde_keystores`. Each TDE-enabled vPDB will have its own directory within the `oracle_tde_keystores` directory, identified by the vPDB name, group name, and a unique identifier, separated by an underscore. If the keystores root directory is not specified, then it defaults to the toolkit directory path.

For example, if the keystores root directory is `/work` (or keystores root is not specified, and the toolkit directory is `/work`), the artifact directory for the vPDB `tde_vpdb` in the group `Encrypted` could be

```
/work/oracle_tde_keystores/tde_vpdb_Encrypted_ce7a47e6-8860-4398-bab0-cf0233fc5e3c
```

Within the artifact directory, there is a subdirectory `exported_keys` which contains within it the exported keyfiles for each timeflow associated with that vPDB. Each time an export is performed, a new exported keyfile is

generated with a timestamp. The contents of the artifact directory may change for future releases, but the path to the artifact directory and the naming convention is not anticipated to change.

As the default keystores root directory root is at the same level as the toolkit directory, it will not be overwritten if a host is refreshed through the Delphix Engine and the toolkit updated. It is the customer's responsibility to maintain the artifact directory and ensure that the contents are not lost, as a disk failure could prevent a TDE-enabled vPDB from being accessed. Thus it is recommended that the keystores root directory be on a disk which is regularly backed up.

If a vPDB is moved to a different host (either through the migrate workflow or an enable after a failover, then the artifact directory will need to be copied to the new target host. See [Migrating a TDE-enabled vPDB](#) for details on the manual steps needed for migration.

The artifact directory is not removed when a TDE-enabled vPDB is deleted; the customer can remove it after confirming that the vPDB has been removed (including from any replicated Delphix Engines).

**[-]** For TDE enabled vPDBs, use manual hooks in configure clone and Pre-snapshot. You should not use hooks utility feature with TDE enabled virtual database.

**[-]** For versions 19.3 or later, follow the below guidelines if you see the following error:

- ORA-01017: invalid username/password; logon denied or ORA-28040 During cloning: No Matching Authentication Protocol

EBS application database user accounts created in the earlier release use a case-insensitive password version from an earlier release authentication protocol, such as the 10G password version. In case, if your database release user account passwords have not been reset and the following configuration persists:

On source: The database server has been configured with SEC\_CASE\_SENSITIVE\_LOGON set to FALSE, so that it can only authenticate users who have a 10G case-insensitive password version, then, on Target container VDB, it becomes necessary to set the SEC\_CASE\_SENSITIVE\_LOGON to FALSE, to make authentication of users successful.

To take advantage of the password protections introduced in Oracle Database 19c, users must change their passwords. Occasionally, it is necessary to restart the database to resolve connectivity to the database. This is atypical but may be necessary.

To set-up target:

On target container database, alter system set SEC\_CASE\_SENSITIVE\_LOGON=FALSE scope=both;

Configure clone first hook for a 19c multi-tenant high privileged user:

- Configure clone hook will blindly create and start the services, No validation on services has been implemented, but this will get improve over time.

```

```

**F** The remaining configure clone & Pre-snapshot hooks remains unchanged. It is mandatory to use hooks mentioned in documentation while provisioning EBS virtual PDB or database.

### Refreshing and rewinding a TDE-enabled vPDB

Just like a non-TDE-enabled vPDB, a TDE-enabled vPDB can be refreshed from the dSource or rewound to a previous snapshot or point in time. In each case, no additional manual steps or input from the user is required. The first step of a refresh or rewind operation is to disable the existing vPDB, which will result in a new keyfile exported to the artifact directory. The appropriate snapshot files are then mounted for the auxiliary database so that it can be recovered and brought to a consistent state. Since the vPDB is TDE-enabled, a keystore is needed for the recover operation. For a refresh, the Delphix Engine will use the parent keystore, and for a rewind, the Delphix Engine will use the target keystore, as shown below.

### Key rotation

There are two potential places for keys to be rotated in a vPDB environment:

1. dSource: If the dSource keys are rotated and a new snapshot taken with the new key, the customer is responsible for updating the parent keystore before refreshing from the later snapshot encrypted with the new key. The parent keystore would then contain both the new key and the original keys.
2. Target: If the target CDB keys are rotated, the target keystore will be updated. This is why the Delphix Engine uses the target keystore for rewind operations.

In either scenario, the keystore used for recovery will contain the current and all prior keys used to encrypt the datafiles and archive logs, for both the vPDB and CDB used in the auxiliary container.

## vPDB encryption key management

During the provisioning process of a TDE-enabled vPDB, Delphix generates a unique encryption key for the vPDB. This unique key is not associated with the parent keystore to ensure that no keys from the parent are imported by the target. During refresh and rewind operations, Delphix reuses that key after recovery has finished. It is possible to customize the key that is used by updating the `tdeKeyIdentifier` parameter of the source via the CLI. If a valid `key_id` is entered for a key that is already present in the keystore, that key will be used as the active encryption key for the vPDB at the end of refresh/rewind. If the field is unset, Delphix will generate a new encryption key for the vPDB to be used from that point onward. This procedure is the same when using a vCDB, in which case Delphix will also generate a new unique encryption key for the vCDB that is reused for refresh and rewind, and which can be customized by updating the `tdeKeyIdentifier` parameter of the CDB source. See the CLI steps for [Locating and updating the value of tde encryption key](#)

## EBS database port flexibility/customization

This topic describes the process of provisioning VDBs in EBS dbTechStack & Appstier plugin to run on a customized port.

### Provisioning the EBS dbTechStack

1. Log in to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dbTechStack dSource**.
5. Click the **TimeFlow** tab.
6. Select a dSource **snapshot**.
7. Click **Provision**. The **Provision VDB** wizard will open.
8. Select an **Environment**. This environment will host the virtual dbTechStack and be used to execute hook operations specified in step 15 in the **s** section.
9. Select **E-Business Suite R12.2 dbTechStack** from the **Installation** dropdown.
10. Select an **Environment User**.
11. This user should be the `oracle` user outlined in [Preparing target EBS R12.2 environments for provisioning](#)
12. Enter a **Mount Path** for the virtual dbTechStack files.
13. Enter the **EBS-specific parameters** for the virtual dbTechStack. A subset of these parameters is discussed in more detail below.
  - a. The **Privileged OS Account (Optional)** field should contain the high privileged user when the low privileged user is being used for provisioning.
  - b. The **Target APPS Password** is the new apps password that is required to configure virtual dbTechStack. This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone` process.
  - c. Provide source oracle home directory name relative to oracle base installation directory that was provided during linking of dbTechStack in Oracle Home input field.
  - d. Ensure that the **Target DB Hostname** value is the short hostname, not the fully-qualified hostname.
  - e. The **Target DB/CDB SID** is the new database SID (CDB SID in case of 19c) that is required to configure virtual dbTechStack.
  - f. The **Target PDB Name** field is added for the pluggable database to be configured for Oracle 19c database. Please leave this field empty when using Oracle 11g/12c database.
  - g. Provide **Target utl\_file\_dir**, the default value for this field will be `"/var/tmp"`. The `utl_file_dir` initialization parameter is deprecated in Oracle Database 12c Release 2 (12.2.0.1), and maybe unsupported in a future release.
  - h. Provide **DISPLAY Variable**, the default value is `hostname:0.0`
  - i. [Optional] **Custom Database Port Number** - Provide the port number on which database listener must run. **Note:** Enter a numeric port value in this field only if you want to use DB port customisation. Leaving this field blank automatically uses the default port based on port pool. The custom database port number is applicable only for Oracle 19c database.  
**Note:** If you want the dbTechStack and listener to run on custom DB port, it is recommended to provide **Target Port Pool** value either as default or 0; also the **Target Port Pool** value in dbTechStack is not related with **Run/Patch Edition Port Pool** value in Appstier.
  - j. Provide **Target Port Pool**, please provide a port pool that is available. By default, the value is 1. The range for this value is 0 to 99.
  - k. Enable the **Disable RAC** option if you want to permit the Delphix Engine to automatically disable the RAC option for the binaries when applicable. This option is necessary if provisioning from a dSource with RAC dbTier because the binaries are relinked with the `rac_on` option even after running

- `adcfgclone` . If the source binaries already have the RAC option disabled (also the case for SI dbTier), the Delphix Engine ignores this option.
- l. Enable the **Cleanup Before Provision** option if you want to permit the Delphix Engine to automatically clean up stale EBS configuration during a refresh. This option is recommended, but only available if your Oracle Home is patched with Oracle Universal Installer (OUI) version 10.2 or above.
    - i. With this option enabled, the Delphix Engine will inspect the target environment's oraInventory prior to refreshing this virtual dbTechStack. If any Oracle Homes are already registered within the specified **Mount Path**, the Delphix Engine will detach them from the inventory prior to running `adcfgclone`. These homes must be detached prior to running post-clone configuration. If they are not detached, `adcfgclone` will fail, citing conflicting oraInventory entries as an issue.
    - ii. Without this option enabled, Oracle Homes that conflict with the specified **Mount Path** will be reported in an error instead of automatically detached. For refresh to succeed, you must manually detach conflicting Oracle Homes prior to refresh.
  - m. Provide **Oracle OS User and Group**, it's optional.

Provision Plugin-based VDB ✕

---

- Target Environment
- Target Configuration
- Configuration
- Policies
- Masking
- Hooks
- Summary

### Target Configuration

Configure the target environment.

---

Mount Path \*

`/u01/oracle/vis`

Path where the data will be mounted

Privileged OS Account (Optional)

`oravis`

This privileged user's username will be used to provision EBS dbTechStack. The privileged user's username should begin with a lower case letter or an underscore, followed by lower case letters, digits, underscores, or dashes. They can end with a dollar sign. Leave this field blank if you do not want to use privilege elevation.

Target APPS Password

This will be used to reconfigure the target application once the database is provisioned.

Username and Password ▼

User name

`apps`

Password \*

\*\*\*\*

Oracle Home \*

`19c`

Path where ORACLE\_HOME will be relative to where the application data is being mounted.

Target DB Hostname \*

`ukexadb01`

Target system database (short) hostname to pass to addgtdone.

Target DB/CDB SID \*

`TGTCDDB`

The new SID for the database (or CDB name in case of 19c DB) that will be provisioned.

Target PDB Name

`TGTPDB`

Cancel Back Next Submit

Provision Plugin-based VDB ×

- Target Environment
- Target Configuration
- Configuration
- Policies
- Masking
- Hooks
- Summary

**TGTCDDB**  
The new SID for the database (or CDB name in case of 19c DB) that will be provisioned.

**TGTPOB Name**  
**TGTPOB**

The name of POB that will be provisioned if using a 19c DB.

Target utl\_file\_dir \*  
**/var/tmp**

The new utl\_file\_dir (Absolute Path).

DISPLAY Variable \*  
**ukexadb01:0.0**

The value for the DISPLAY variable, for example 'hostname:0.0'.

Custom Database port number  
**34001**

Port number on which the database listener must run. Provide this value only if DB port customisation is required. Leave this field blank if you wish to use the default port based on port.pool. Note: This is available only for 19c DB.

Target Port Pool  
**0**

The new port pool for this environment. Should be between 0 and 99.

**Disable RAC option \***

Allow Delphix to automatically disable RAC option for the binaries if applicable. If the source binaries already have the RAC option disabled, this option is ignored.

**Cleanup Before Provision**

Allow Delphix to automatically perform necessary cleanup of stale EBS configuration prior to running adfclone.

Oracle OS User  
The Oracle OS user on the target environment.

Oracle OS Group  
The Oracle OS group on the target environment.

Cancel Back Next Submit

14. Click **Next**.
15. Enter a **VDB Name**.
16. Select a **Target Group** for the VDB.  
If necessary, click the green **Plus** icon to add a new group.
17. Select a **Snapshot Policy** for the VDB. If necessary, click the **Plus** icon to create a new policy.  
**Note:** When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots. To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more.
18. Click **Next**.
19. Enter any **custom hook operations** that are needed to help correctly manage the virtual dbTechStack files. For more information about these hooks, when they are run, and how operations are written. The Configure Clone hook will be run after the `adcfgclone.pl` tool has both mounted and configured the dbTechStack.
20. Click **Next**.
21. Click **Submit**.

When provisioning starts, you can review the progress of the job in the **Datasets** panel, or in the **Job History** panel of the **Dashboard**. When provisioning is complete, the dbTechStack VDB will be included in the group you designated and listed in the **Datasets** panel. If you select the dbTechStack VDB in the **Datasets** panel and click the **Configuration** tab, you can view information about the virtual files and its Data Management settings.

For tips on monitoring the progress of dbTechStack provisioning, see [Monitoring EBS R12.2 dbTechStack provisioning progress](#)

### Provisioning the EBS appsTier

1. Log in to the **Delphix Management** application using **Admin** credentials.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier dSource**.
5. Select a dSource **snapshot**. All snapshots will have staged configuration prepared by `adpreclone.pl` and any hook operations placed on the dSource.
6. Click **Provision**. The **Provision VDB** wizard will open.

7. Select an **Environment**. This environment will host the virtual appsTier and be used to execute hook operations specified in a few steps. This environment will also run the WebLogic Admin server (Web Administration service) for the virtual appsTier. If you are provisioning a multi-node appsTier, you will be able to specify additional environments to host the virtual appsTier in a few steps.
8. Select E-Business Suite R12.2 appsTier from the **Installation** dropdown.
9. Select an Environment User. This user should be the `app1mgr` user-outlined in [Preparing target EBS R12.2 environments for provisioning](#)
10. Enter a **Mount Path** for the virtual appsTier VDB.If you are provisioning a multi-node appsTier, this mount path will be used across all target environments.
11. Enter the **EBS-specific parameters** for the virtual appsTier. A subset of these parameters are discussed in more detail below.

Provision Plugin-based VDB ×

- Summary

### Target Configuration

Configure the target environment.

Mount Path \*

`/u02/oracle/APPS`

Path where the data will be mounted on

Privileged OS Account (Optional)

`app1mgr`

This privileged unix username will be used to provision EBS appsTier. The unix privileged usernames should begin with a lower case letter or an underscore, followed by lower case letters, digits, underscores, or dashes. They can end with a dollar sign. Leave this field blank if you do not want to use privilege elevation.

**Target APPS Password**

The desired APPS password for the EBS instance. A password change will be performed if this password does not match that of the source EBS instance.

Username and Password

User name

`apps`

Password \*

.....

**Target Weblogic AdminServer Password**

This will be used to reconfigure the target application once provisioned. A password change will be performed if this password does not match that of the source EBS instance.

Username and Password

User name

`weblogic`

Password \*

.....

**SYSTEM Password**

The SYSTEM password for this EBS instance. This password is used to change the EBS instance's password. This should be the password from which this instance is being refreshed. This field can be left blank if the APPS password is the same as the source APPS password.

Cancel Back Next Submit

- a. **Privileged OS Account (Optional)** field should contain high privileged user when low privileged user is being used for provisioning.
- b. The **Target APPS Password** is the new apps password that is required to configure and manage the virtual appsTier. This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone`, `adstrtal`, and `adstpall` processes.
- c. The **Weblogic AdminServer Password** is the new WebLogic password required to configure the virtual appsTier. A password change will be performed if this password does not match that of the source EBS instance. This password is encrypted when stored within the Delphix Engine and is available as an environment variable to the `adcfgclone`, `adstrtal`, and `adstpall` processes.
- d. The **SYSTEM Password** is required to configure the virtual appsTier with the new apps password. This password is not required if the Target Apps Password is the same as the source.
- e. Provide the Target Application hostname.
- f. The **Target DB/PDB SID** is the new database SID (PDB SID in case of 19c) that is required to configure and manage the virtual appsTier.
- g. Provide the Target DB server node hostname.
- h. Provide **Target DB Domain Name**, this will be provided to the `adcfgclone`.
- i. Delphix recommends specifying an **Instance Home Directory** under the **Mount Path** so that instance-specific EBS files live on Delphix-provided storage.

## Provision Plugin-based VDB

- Target Environment
- Target Configuration**
- Configuration
- Policies
- Masking
- Hooks
- Summary

Target Application Hostname \*  
**ukapp99**

Target system application server (short) hostname to pass to adcfclone.

---

Target Application File System Owner (Optional)

The file system owner for applications on the target environment. This is an optional parameter which will be used if adcfclone requires it.

Target DB/PDB SID \*  
**TGTPDB**

The SID for target system database (or PDB Name in case of 19c DB).

Target DB Server Node \*  
**ukexadb01**

Target system database server (short) hostname to pass to adcfclone.

---

Target DB Domain Name \*  
**delphix.com**

Target system database domain name to pass to adcfclone.

Instance Home Directory (Absolute Path) \*  
**/u02/oracle/APPS**

Path where the INST\_TOP for this copy should be created from (Absolute Path).

---

### Services

Root Service

Web Entry Point Services

Web Application Services

Batch Processing Services

Other Services

---

DISPLAY Variable \*  
**ukapp99:0.0**

The value for the DISPLAY variable, for example 'hostname:0.0'.

For example, if the provided **Mount Path** is `/u01/oracle/VIS`, then providing an **Instance Home Directory** of `/u01/oracle/VIS` would allow EBS to generate virtual application INST\_TOP in `/u01/oracle/VIS/fs1/inst/apps/<CONTEXT_NAME>` and `/u01/oracle/VIS/fs2/inst/apps/<CONTEXT_NAME>`.

- i. If you are provisioning a single-node appsTier, this recommendation is OPTIONAL; putting instance-specific EBS files on Delphix-provided storage merely eases the administration of the virtual EBS instance.
- ii. If you are provisioning a multi-node appsTier, this recommendation is REQUIRED; the Delphix Engine's automation requires that all nodes in the appsTier have access to instance-specific files via Delphix-provided storage.
- j. Ensure that the **Target Application Hostname** and **Target DB Server Node** values are the short hostnames, not the fully-qualified hostnames.
- k. Select **Services**, by default all the **Root**, **Web Entry Point**, **Web Application** and **Batch Processing** would be checked. In case you are using multinode environment and want to start a few services on a secondary node then this field is going to be very useful for you.
- l. Provide **DISPLAY Variable**, the default value is hostname:0.0
- m. [Optional] **Custom Database Port Number** - Provide the port number on which database listener must run. **Note:** Enter a numeric port value in this field only if you want to use DB port customisation, this value should match with the custom database port number given during the DBTechStack

provisioning. Leaving this field blank automatically uses the default port based on port pool. The custom database port number is applicable only for Oracle 19c database.

- n. Provide **Target Run Edition Port Pool**, the value of this field should be 0 to 99.
- o. Provide **Target Patch Edition Port Pool**, the value of this field should be 0 to 99. This value should be Target Run Edition Port Pool plus 1. For example, if Run Edition Port Pool is 9 then the value should be 10.

**Note:** Target Apps server **RUN Edition Port Pool** value cannot be the same as **PATCH Edition Port Pool** value of source Apps server.

Provision Plugin-based VDB ✕

- Target Environment
- Target Configuration
- Configuration
- Policies
- Masking
- Hooks
- Summary

Custom Database port number

**34001**

Port number on which the database listener is running. Provide this value only if DB port customization was done during DBtechstack provisioning. Leave this field blank if you have used port pool values. Note: This is available only for 19c DB.

Target Run Edition Port Pool\*

**10**

The new Run Edition port pool for this environment. Should be between 0 and 99. Note: If Custom DB port is used, kindly provide port pool values different from source/target.

Target Patch Edition Port Pool\*\*

**20**

The new Patch edition port pool for this environment. Should be between 0 and 99. Note: If Custom DB port is used, kindly provide port pool values different from source/target.

EBS AppsTier Process Timeout (in minutes)\*

**10**

If this timeout value is exceeded while stopping application services during a stop or refresh operation any long-running appsTier processes will be terminated.

EBS AppsTier Provision/Refresh Timeout (in hours)\*\*

**8**

Timeout value, in hours. This value will control the timeout for appsTier file provision/refresh operation execution.

Java Color Scheme (Optional)\*

**Swan**

Choose any of the following colors (Swan, Blue, Khaki, Olive, Purple, Red, Teal, Titanium) to set Java Color Scheme for EBS appsTier Java based Forms Interface.

Target System Proxy Hostname (Optional)

**proxyhost**

Enter a valid proxy hostname. This is an optional parameter which will be used if adcfclone requires it.

Target System Proxy Port (Optional)

**80**

Enter a valid proxy port. This is an optional parameter which will be used if adcfclone requires it.

**Cleanup Before Provision**

Allow Delphix to automatically perform necessary cleanup of stale EBS configuration prior to running adcfclone.

**Start Services After Provision**

Allow Delphix to start the services of EBS appsTier after provisioning.

Additional Nodes

+ Add

Cancel Back Next Submit

- p. The **EBS AppsTier Timeout** is required to terminate all the long-running appsTier processes which have exceeded the timeout value when stopping the applications as part of a refresh. This timeout will be calculated in minutes. For example, if set to 30, then we run adstpall at the start of the refresh, and if after 30 minutes the application has not stopped, then the processes will be terminated to allow the refresh to continue.
- q. The **EBS AppsTier Provision/Refresh Timeout** is required to terminate configure and cloning via `adcfclone` process which have exceeded the timeout as part of a provision/refresh. This timeout will be calculated in hours and the default value will be 8 hours. For example, if set to 9, then plugin will detect a timeout after 9 hours instead of getting in a hung state and UI error for the same will be prompted.
- r. The **Java Color Scheme** is an **optional** parameter and is used to change the JAVA color for provisioned Oracle EBS JAVA based form interface. Please choose any of the following colors (Swan, Blue, Khaki, Olive, Purple, Red, Teal, Titanium) to set Java Color Scheme for EBS appsTier java-based forms interface.
- s. Provide **Target System Proxy Hostname (Optional)**, This is an optional parameter that will be used if `adcfclone` requires it.
- t. Provide **Target System Proxy Port (Optional)**, This is an optional parameter that will be used if `adcfclone` requires it.
- u. Enable the **Cleanup Before Provision** option if you want to permit the Delphix Engine to automatically cleanup stale EBS configuration during a refresh. This option is recommended, but only available if your Oracle Home is patched with Oracle Universal Installer (OUI) version 10.2 or above.
  - i. With this option enabled, the Delphix Engine will inspect the target environment's oraInventory prior to refreshing this virtual appsTier. If any Oracle Homes are already registered within the specified **Mount Path**, the Delphix Engine will detach them from the

- inventory prior to running `adcfgclone`. These homes must be detached prior to running post-clone configuration. If they are not detached, `adcfgclone` will fail, citing conflicting oraInventory entries as an issue. The Delphix Engine will also remove any conflicting INST\_TOP directories left on the environment. Non-conflicting INST\_TOP directories will not be modified.
- ii. Without this option enabled, Oracle Homes or INST\_TOP directories that conflict with the specified **Mount Path** or desired INST\_TOP location will be reported in errors instead of automatically cleaned up. For refresh to succeed, you must manually detach conflicting Oracle Homes and manually remove conflicting INST\_TOP directories prior to refresh.
  - v. Enable the **Start Services After Provision** option if you want to permit the Delphix Engine to automatically start the services for EBS appsTier after provisioning.
    - i. With this option enabled, the Delphix Engine will start all the services of EBS appsTier after provisioning.
    - ii. Without this option enabled, the Delphix Engine will **NOT** start the services of EBS appsTier after provisioning. This will allow customers to prevent EBS services from being started at the conclusion of provisioning or refreshing. That way, customers can perform post-clone processing automation using a configure-clone hook without having to stop services first.
  - w. If you are provisioning a multi-node appsTier, enter additional appsTier nodes as **Additional Nodes**.
    - i. Select the Environment for the secondary node.
    - ii. The **Environment User** for each node should be the `applmgr` user-outlined in [Preparing target EBS R12.2 environments for provisioning](#).
    - iii. Ensure that the **Hostname** value for each node is the short hostname, not the fully-qualified hostname.
    - iv. Provide DISPLAY Variable, the default value is hostname:0.0.
    - v. The **Mount Path** is not configurable for each node individually. The **Mount Path** provided for the primary environment will be used for each additional node.
12. Click **Next**.
  13. Enter a **VDB Name**.
  14. Select a **Target Group** for the VDB. If necessary, click the **Plus** icon to add a new group.
  15. Select a **Snapshot Policy** for the VDB. If necessary, click the **Plus** icon to create a new policy.
 

**Warning:** When Snapshot is running against the dbTechStack, database, or appsTier, the Delphix Engine also executes pre-clone logic to ensure the latest configuration is staged in the captured snapshots. Unfortunately, if multiple Snapshots are running against the same EBS instance concurrently, this pre-clone logic may fail and produce bad snapshots. To avoid SnapSync conflicts, spread out your SnapSync policies for an EBS instance by one hour or more. Click **Next**.
  16. Enter any **custom hook operations** that are needed to help correctly manage the virtual appsTier. The Configure Clone hook will be run after the `adcfgclone.pl` tool has both mounted and configured the appsTier. All hook operations run against the environment specified for provision. For a multi-node appsTier, hook operations never run against additional nodes specified.
  17. Click **Next**.
  18. Click **Submit**.
 

**Note:** dbTier Must Be Accessible During appsTier Provisioning  
Post-clone configuration will fail if the appsTier cannot connect to the database. Ensure the target dbTier is accessible to the appsTier during the provisioning process. Ensure both the virtual database and database listener are running.

**Note:**  
If your source setup is EBS ISG enabled, then during virtual AppsTier creation on the target server, perform post cloning steps as described in [Installing Oracle E-Business Suite Integrated SOA Gateway, Release 12.2](#) (Doc ID 1311068.1).

19. For tips on monitoring the progress of appsTier provisioning, see [Monitoring EBS R12.2 appsTier provisioning progress](#). Once all three EBS virtual datasets have been provisioned successfully, your virtual EBS instance should be running and accessible.

**i** **Rewind Operation on Snapshot**

Perform the rewind operation on the snapshot after Appstier provisioning in the following sequence.

1. Take a snapshot of the Database VDB after Appstier provision.
2. Stop the appsTier, DB, and dbTechStack one by one.
3. Rewind dbTechStack, DB, and appsTier one by one.

If the DB snapshot was taken before appsTier provisioning, rewinding the DB will cause loss of new data updated by appsTier during provisioning and the next operation of appsTier rewind will fail. So, to ensure that the Rewind operation of appsTier succeeds, take a snapshot of DB after Appstier provision.

## Managing data operations for virtual EBS instances

This section contains the following topics:

- [Starting and stopping a virtual EBS instance](#)
- [Rewinding a virtual EBS instance](#)
- [Refreshing a virtual EBS instance](#)
- [Enabling and disabling a virtual EBS instance](#)
- [Deleting a virtual EBS instance](#)
- [Modifying the appsTier topology](#)
- [Replicating a virtual EBS instance](#)
- [Upgrading a Delphix Engine hosting a virtual EBS instance](#)
- [Migrating an EBS VDB](#)

## Starting and stopping a virtual EBS instance

This topic describes the process of starting and stopping a virtual Oracle E-Business Suite (EBS) instance.

You can start and stop virtual EBS instances through the **Delphix Management** application or through the standard Oracle command-line interface (CLI) utilities, `adstrtal` and `adstpall`. The Delphix Engine will show the dbTechStack and appsTier as running as long as there are processes using the dbTechStack and appsTier filesystem mounts on the target environments.

 Be careful! Services running on the appsTier depend on the availability of services on the dbTier. The steps below are explicitly ordered with these dependencies in mind. Executing steps out of order may lead to errors in accessing the virtual EBS instance.

### Stopping

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier vFiles** for your EBS instance.
5. Click the **Stop** icon.  Stopping the appsTier will run Oracle's `adstpall.sh` utility. For multi-node appsTier, secondary nodes will be stopped sequentially, followed by the primary node.  
**Note:** Stopping the appsTier may take a long time. The Delphix Engine will wait for all Oracle application processes to exit before declaring the appsTier as stopped.
6. Select the **VDB** utilized by your EBS instance.
7. Click the **Stop** icon. This action will shutdown the database instance.
8. Select the **dbTechStack vFiles** hosting your virtual EBS database.
9. Click the **Stop** icon. Stopping the dbTechStack will shutdown the database listener.

### Starting

1. Login to the **Delphix Management** application using **Delphix Admin** credentials.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dbTechStack vFiles** hosting your virtual EBS database.
5. Click the **Start** icon.
6. Starting the dbTechStack will start the database listener.
7. Select the **VDB** utilized by your EBS instance.
8. Click the **Start** icon. Starting the database will open the database.
9. Select the **appsTier vFiles** for your EBS instance.
10. Click the **Start** icon. Starting the appsTier will run Oracle's `adstrtal.sh` utility. For multi-node appsTier, the primary node will be started first, followed by secondary nodes sequentially.

## Rewinding a virtual EBS instance

This topic describes the process of rewinding a virtual Oracle E-Business Suite (EBS) instance.

 Changes applied to EBS and picked up only in some dSource snapshots may make certain combinations of snapshots across the appsTier and dbTier incompatible. When provisioning, refreshing or rewinding a virtual EBS instance, be sure the points in time you select for each dataset are compatible with each other.

 Be careful! Services running on the appsTier depend on the availability of services on the dbTier. The steps below are explicitly ordered with these dependencies in mind. Executing steps out of order may lead to errors in accessing the virtual EBS instance.

### Prerequisites

The appsTier **Instance Home Directory** of the virtual EBS instance must reside under the specified **Mount Path**.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier vFiles** for your EBS instance.
5. Click the **Stop** icon to shutdown the appsTier services.
6. Select the **VDB** utilized by your EBS instance.
7. Click the **Stop** icon to shutdown the database.
8. Select the **dbTechStack vFiles** hosting your virtual EBS database.
9. Click the **Stop** icon to shutdown the database listener.
10. Rewind the dbTechStack vFiles.
  - a. Select a **snapshot**.
  - b. Click the **Rewind** button.
11. Rewind the EBS VDB.
  - a. Select a **snapshot**.
  - b. Click the **Rewind** button.
12. Rewind the appsTier vFiles.
  - a. Select a **snapshot**.
  - b. Click the **Rewind** button.

Once you have rewound all three EBS virtual datasets successfully, your virtual EBS instance should be running and accessible.

## Refreshing a virtual EBS instance

This topic describes the process of refreshing a virtual Oracle E-Business Suite (EBS) instance.

 Changes applied to EBS and picked up only in some dSource snapshots may make certain combinations of snapshots across the appsTier and dbTier incompatible. When provisioning, refreshing, or rewinding a virtual EBS instance, be sure the points in time you choose for each dataset are compatible with each other.

 Be careful! Services running on the appsTier depend on the availability of services on the dbTier. The steps below are explicitly ordered with these dependencies in mind. Executing steps out of order may lead to errors in accessing the virtual EBS instance.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**
4. Select the **appsTier vFiles** for your EBS instance.
5. Click the **Stop** icon to shut down the appsTier services.
6. Select the **VDB** utilized by your EBS instance.
7. Click the **Stop** icon to shut down the database.
8. Select the **dbTechStack vFiles** hosting your virtual EBS database.
9. Click the **Stop** icon to shut down the database listener.
 

**Warning:** If you did NOT specify the **Cleanup Before Provision** option for either your virtual dbTechStack or appsTier, you must manually clean up your target environments prior to refreshing. If you have specified this option for both datasets, no manual work is required.

To manually clean up a target environment prior to refresh, remove instance-specific directories and or inventory entries that will conflict with files and entries recreated during the refresh. Without this clean-up, post-clone configuration performed during a refresh will fail with an error claiming that a conflicting EBS instance is already installed.
10. Refresh the dbTechStack vFiles.
  - a. On the vFiles, click the **Refresh**.
  - b. Select a **snapshot** from which to refresh.
11. Refresh the EBS VDB.
  - a. On the VDB, click the **Refresh**.
  - b. Select a **snapshot** from which to refresh.
12. Refresh the appsTier vFiles.
  - a. On the vFiles, click the **Refresh**.
  - b. Select a **snapshot** from which to refresh.

Once you have refreshed all three EBS virtual datasets successfully, your virtual EBS instance should be running and accessible.

## Enabling and disabling a virtual EBS instance

This topic describes the process of enabling and disabling a virtual Oracle E-Business Suite (EBS) instance.

An enabled virtual EBS instance will be running and fully available to end-users. A disabled virtual EBS instance will be neither running nor mounted to the target environments.

Be careful! Services running on the appsTier depend on the availability of services on the dbTier. The steps below are explicitly ordered with these dependencies in mind. Executing steps out of order may lead to errors in accessing the virtual EBS instance.

### Disabling

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier vFiles** for your EBS instance.
5. From the Actions menu (...) select **Disable**. Disabling the appsTier vFiles will stop the appsTier services and unmount the appsTier files.  
**Note:** Stopping the appsTier may take a long time. The Delphix Engine will wait for all Oracle application processes to exit before declaring the appsTier as stopped.
6. Select the **VDB** utilized by your EBS instance.
7. From the Actions menu (...) select **Disable**. Disabling the VDB will stop the database instance and unmount the data files.
8. Select the **dbTechStack vFiles** hosting your virtual EBS database.
9. From the Actions menu (...) select **Disable**. Disabling the dbTechStack vFiles will stop the database listener and unmount the dbTechStack files.

Once you have disabled all three EBS virtual datasets successfully, your virtual EBS instance should be fully removed from the target environment.

### Enabling

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dbTechStack vFiles** hosting your virtual EBS database.
5. From the Actions menu (...) select **Enable**. Enabling the dbTechStack vFiles will mount the dbTechStack files and start the database listener.
6. Select the **VDB** utilized by your EBS instance.
7. From the Actions menu (...) select **Enable**. Enabling the VDB will mount the data files and start the database instance.
8. Select the **appsTier vFiles** hosting your virtual EBS database.
9. From the Actions menu (...) select **Enable**. Enabling the dbTechStack vFiles will mount the appsTier files and start the application services.

Once you have enabled all three EBS virtual datasets successfully, your virtual EBS instance should be running and accessible.

## Deleting a virtual EBS instance

This topic describes the process of deleting a virtual Oracle E-Business Suite (EBS) instance.

 Be careful! Services running on the appsTier depend on the availability of services on the dbTier. The steps below are explicitly ordered with these dependencies in mind. Executing steps out of order may lead to errors in accessing the virtual EBS instance.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **appsTier vFiles** for your EBS instance.
5. Delete the appsTier vFiles by clicking the **Trash Can** icon in the lower left-hand corner.
6. Select the **VDB** utilized by your EBS instance.
7. Delete the VDB by clicking the **Trash Can** icon in the lower left-hand corner.
8. Click **Manage**.
9. Select **Environments**.
10. Select the **target dbTier environment**.
11. Click the **Databases** tab.
12. In the list of **Installation Homes** on the environment, click the **Trash Can** icon next to the dbTechStack Oracle Home you want to delete.
13. Click **Manage**.
14. Select **Datasets**.
15. Select the **dbTechStack vFiles** for your EBS instance.
16. Delete the dbTechStack vFiles by clicking the **Trash Can** icon in the lower left-hand corner.
17. Clean up any files that the virtual EBS instance might have created outside of the Delphix mount points on the target environments. These typically include the instance-specific directories, oraInventory files, and oraTab entries.

Once you have deleted all three EBS virtual datasets successfully, your virtual EBS instance should be fully removed from the target environments.

## Modifying the appsTier topology

This topic describes the process of modifying the appsTier topology of a virtual EBS instance.

### appsTier Topology Changes Invalidate Rewind

If you modify the appsTier topology of a virtual EBS instance, all snapshots in existence prior to the modification will no longer be valid for rewind. The appsTier topology in the snapshots will no longer match the Delphix Engine's configuration and rewind targeting these snapshots will fail if attempted.

### Procedure

1. Disable the virtual EBS instance by following the procedure outlined in [Enabling and disabling a virtual EBS instance](#)
2. Select the **appsTier vFiles** for your EBS instance.
3. On the back of the card, modify the **EBS-specific parameters** for the virtual appsTier. This process will normally entail adding or deleting **Additional Nodes** and configuring its corresponding **Services**.
4. Apply the configuration changes by refreshing the entire virtual EBS instance. Follow the procedure outlined in [Refreshing a virtual EBS instance](#)

## Replicating a virtual EBS instance

This topic describes the process of replicating a virtual Oracle E-Business Suite (EBS) instance.

### Replication

1. Login to the *source* Delphix Engine's **Delphix Management** application.
2. Configure replication between the source Delphix Engine and a target Delphix Engine. For a detailed outline of the replication process, see [Configuring replication](#).
3. Select the **dbTechStack vFiles**, **VDB**, and **appsTier vFiles** objects to be replicated. These objects have dependencies on all other Delphix Engine objects relevant to the virtual EBS instance: you do not need to specify any additional objects for EBS replication.
4. Schedule or perform the replication.

### Failover

1. Login to the *target* Delphix Engine's **Delphix Management** application.
2. Failover the replica **dbTechStack vFiles**, **VDB**, and **appsTier vFiles**. Failing over these object will sever future replication, but will not enable the datasets. For a detailed outline of the failover process, see [Controlled failover](#)
3. Enable the dbTier and appsTier environments.
  - a. Click **Manage**.
  - b. Select **Environments**.
  - c. For each environment, from the Actions menu (...) select **Disable**.
4. Enable the virtual EBS instance by following the procedure outlined in [Enabling and disabling a virtual EBS instance](#)

### Provisioning from a replicated EBS instance

You can provision new virtual EBS instances from replicated datasets regardless of whether these datasets have been failed over. The provisioning process for each version of EBS is outlined in [Virtualizing Oracle E-Business suite](#). For more information about provisioning from replicated datasets, see [Replicating a virtual EBS instance](#)

## Upgrading a Delphix Engine hosting a virtual EBS instance

This topic describes the process of upgrading a Delphix Engine hosting a virtual Oracle E-Business Suite (EBS) instance.

### Procedure

1. Disable the virtual EBS instance by following the procedure outlined in [Enabling and Disabling a Virtual EBS Instance](#)
2. Once you have safely disabled the virtual EBS instance, upgrade the Delphix Engine by following the procedure outlined in [Upgrading the Delphix Engine](#)
3. Enable the virtual EBS instance by following the procedure outlined in [Enabling and Disabling a Virtual EBS Instance](#)

## Migrating an EBS VDB

This topic describes how to migrate an EBS Virtual Database (VDB) from one target environment to another.

There may be situations in which you want to migrate a virtual database to a new target environment, for example when upgrading the host on which the VDB resides, or as part of a general data center migration. This is easily accomplished by first disabling the database, then using the Migrate VDB feature to select a new target environment.

There are three components for any EBS environment - dbTechStack, Database, and appsTier. Whenever we create virtual copies for any EBS environment, we provision these components in the following sequence: (1) dbTechStack (2) Database (3) appsTier.

We can **only** migrate the EBS database (VDB) with the following prerequisite.

### Prerequisite

You should have already set up a new target environment that is compatible with the VDB that you want to migrate.

### Procedure

1. Login to your Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **VDB** you want to migrate.
5. From the Actions menu (...) select **Disable**.
6. Click **Disable** to confirm. When the VDB is disabled, its icon will turn grey.
7. From the Actions menu (...) select **Migrate**.
8. Select the new target environment for the VDB, the user for that environment, and the database installation where the VDB will reside.
9. Select **Migrate** to confirm your selections.
10. From the Actions menu (...) select the **Enable**
11. Click **Enable** to confirm.

Within a few minutes, your VDB will restart in the new environment, and you can continue using it.

- You need to [provision the EBS dbTechStack](#) on the new target environment with a similar DB name VDB that you want to migrate.
- EBS appsTier vFile cannot be migrated, you need to [re-configure the EBS appsTier](#) by modifying the custom configuration for Target DB server node information to the target environment where VDB is migrated.

## Virtual EBS instance recipes

This section contains the following topics:

- [Configuring a Delphix self-service data template for EBS](#)
- [Managing the APPS password](#)
- [Refreshing a target dbTier environment](#)
- [Managing the Weblogic password](#)
- [Working with EBS snapshots](#)

## Configuring a Delphix self-service data template for EBS

This topic describes the process of configuring a Delphix Self-Service (Jet Stream) data template for Oracle E-Business Suite (EBS).

By configuring a data template for EBS, you eliminate the need to order operations applied across the EBS datasets.

The ordering of operations is a result of the dataset dependencies discussed in topics under [Managing Data Operations of Virtual EBS Instances](#), such as [Refreshing a Virtual EBS Instance](#).

### Procedure

1. Create a Delphix Self-Service data template by following the procedure outlined in [Understanding Data Templates](#).
  - a. For EBS, the data template will have three data sources: the dbTechStack, database, and appsTier.
2. Be sure to set the following **ordering of the data sources** when creating the data template. This ordering will ensure that Delphix Self-Service operations do not violate the EBS dataset dependencies.

Order	Dataset
1	dbTechStack
2	Database
3	appsTier

Once you have created a Delphix Self-Service data template, you can configure Delphix Self-Service data containers to manage virtual EBS instances. Delphix Self-Service data containers will follow the ordering of data sources configured in the template. All Delphix Self-Service operations should work as expected for virtual EBS instances.

## Managing the APPS password

This topic outlines how to manage the APPS password on a virtual EBS instance.

The Delphix Engine requires a virtual EBS instance's APPS password in order to manage its dbTechStack and appsTier. This password is encrypted when stored within the Delphix Engine and is exposed as an environment variable to RapidClone tools.

When a virtual EBS instance is being provisioned, the Delphix Engine's copy of the APPS password should match the source EBS instance's APPS password during its time of the snapshot. After provisioning, you can change the APPS password of the virtual instance in both EBS and the Delphix Engine.

### Changing the APPS password

1. Provision a virtual EBS instance.
2. Change the APPS password in the virtual EBS instance. You can perform the password change using Oracle's `FNDCPASS` utility.
3. Stop the virtual appsTier manually using `adstpall`. You cannot stop the virtual appsTier through the Delphix Engine, because the APPS password being stored is now out of sync.
4. Disable the entire virtual EBS instance. For an outline of this process, see [Enabling and Disabling a Virtual EBS Instance](#).
5. Change the APPS password on the dbTechStack.
  - a. Select the **dbTechStack vFiles** hosting your virtual EBS database.
  - b. On the back of the card, click the **Custom** tab.
  - c. Edit the **APPS Password** field.
6. Change the APPS password in any hook operations defined on the EBS virtual database.
  - a. Select the **VDB** utilized by your EBS instance.
  - b. On the back of the card, click the **Hooks** tab.
  - c. Edit the relevant hook operations. Typically, you will need to edit the Pre-Snapshot hook operation running `adpreclone`.
7. Change the APPS password on the appsTier.
  - a. Select the **appsTier vFiles** hosting your virtual EBS database.
  - b. On the back of the card, click the **Custom** tab.
  - c. Edit the **APPS Password** field.
8. Enable the entire virtual EBS instance. For an outline of this process, see [Enabling and Disabling a Virtual EBS Instance](#).

### Refreshing or rewinding

The APPS password stored across individual snapshots of a virtual EBS instance will not be consistent after a password change. Old snapshots of EBS data will refer to a different APPS password than new snapshots of EBS data. To perform a refresh or rewind, you must explicitly manipulate the Delphix Engine's copy of the APPS password to ensure that the virtual EBS instance is being accessed with the correct APPS password at every step.

**i** Recipe Not Needed If Password Not Changed  
 These steps are only necessary if the virtual EBS instance has a different APPS password than the snapshots being targeted by the refresh or rewind.  
 If the APPS password has not been changed, follow the instructions in [Refreshing a Virtual EBS Instance](#) or [Rewinding a Virtual EBS Instance](#).

1. Before refreshing or rewinding the virtual EBS instance, disable the entire virtual EBS instance. For an outline of this process, see [Enabling and Disabling a Virtual EBS Instance](#).

2. Identify the APPS password for the snapshots being targeted by the refresh or rewind. Modify the virtual EBS instance to refer to this password.
  - a. Change the APPS password on the dbTechStack.
    - i. Select the **dbTechStack vFiles** hosting your virtual EBS database.
    - ii. On the back of the card, click the **Custom** tab.
    - iii. Edit the **APPS Password** field.
  - b. Change the APPS password in any hook operations defined on the EBS virtual database.
    - i. Select the **VDB** utilized by your EBS instance.
    - ii. Select the Configuration tab, then select the **Hooks** tab.
    - iii. Edit the relevant hook operations. Typically, you will need to edit the Pre-Snapshot hook operation running `adpreclone` and the Configure Clone operation running `adcfgclone`.
  - c. Change the APPS password on the appsTier.
    - i. Select the **appsTier vFiles** hosting your virtual EBS database.
    - ii. Click the **Custom** tab.
    - iii. Edit the **APPS Password** field.
3. Perform the refresh or rewind while the EBS instance is disabled. See [Refreshing a Virtual EBS Instance](#) or [Rewinding a Virtual EBS Instance](#) for an outline of these processes.

## Refreshing a target dbTier environment

This topic describes how to properly refresh a target dbTier environment hosting an EBS VDB.

When an environment is initially registered with the Delphix Engine, a discovery process is responsible for registering resources such as Oracle Homes, listeners, and databases. When an environment is modified – for example, when an Oracle Home is upgraded or removed – you must run the discovery process again in order to register new resources and unregister removed ones.

The virtual dbTechStack plays a unique role in the Delphix Engine because it acts both as a virtual dataset AND a discovered resource on the target dbTier environment. Because of this unique role, you must mount and start this dataset (hosting the EBS database listener) before you refresh the target dbTier environment.

If you unmount or stop the virtual dbTechStack, the discovery process will assume that the EBS Oracle Home and database listener have been removed from the environment. Further interactions with the EBS VDB will result in an error, because neither the database listener nor Oracle Home appears available to the database.

### Procedure

1. Prior to refreshing a target dbTier environment, ensure that the virtual dbTechStack is both enabled and started. For more information, see [Enabling and Disabling a Virtual EBS Instance](#) and [Starting and Stopping a Virtual EBS Instance](#).
2. Refresh the target dbTier environment.

## Managing the Weblogic password

### Changing the Weblogic password

For existing EBS 12.2 customers who intend to use this WebLogic password change feature need to follow the below steps for their EBS application:

1. Disable all the virtual datasets created on Delphix Engine in the following order:
  - a. appsTier vFiles
  - b. VDB utilized by your EBS instance
  - c. dbTechStack vFiles
2. Disable all the EBS dSource created on Delphix Engine once you have disabled all three EBS virtual datasets in the above step.
3. Upgrade Delphix Engine to 5.3.2.0 release and upload EBS 1.4.0 plugin release.  
Go to Manage>Plugins
  - Upload a plugin file to upgrade the existing plugin by clicking plus (+) symbol.
4. Refresh all host environments added on the Delphix Engine.  
Go to Manage> Environments
  - From the symbol (...) located in the upper left-hand corner, select Refresh All.
5. Change the Weblogic admin password on EBS appsTier vFile.
  - Select the appsTier vFiles hosting your virtual EBS database.
  - Go to Configurations >Custom
  - Update the **Target Weblogic AdminServer Password** field with the password you would like to set for EBS appsTier.
6. Enable all the EBS dSource created on Delphix Engine.
7. Enable all the virtual datasets created on Delphix Engine in the following order:
  - a. appsTier vFiles
  - b. VDB utilized by your EBS instance
  - c. dbTechStack vFiles
8. Verify the changed WebLogic password by logging into the WebLogic console.

EBS 12.2 customers configuring appsTier on a multi-node environment will need to manually enable passwordless SSH on all target nodes *only when* they want to change the Weblogic password and then proceed with EBS appsTier provision. The passwordless SSH **should** be enabled between all nodes and for both low privileged and high privileged user.

### Enabling passwordless SSH between target application nodes

To enable passwordless SSH between target application nodes complete the following

The following is an example of a two-node EBS appsTier.

Node 1: test1-ap1

Node 2: test1-ap2

1. Create Authentication SSH-Keygen Keys on Node 1.

```
[applvis@test1-ap1 ~]$ ssh-keygen -t rsa
Generating public/private rsa key pair.
Enter file in which to save the key (/home/applvis/.ssh/id_rsa):

[applvis@test1-ap2 ~]$
[applvis@test1-ap2 ~]$ hostname -s
test1-ap2
```

## Working with EBS snapshots

Taking a snapshot creates a new snapshot entry in the dSource's Timeflow. The plugin-managed dSource allows you to select the parameters before taking the snapshot. These parameters are provided as an input to pre-snapshot and post snapshot functions. On the other hand, in the default snapshot, the parameters are pre-defined in the dSource environment.

### Snapshot (Default)

This section lists the steps to take a snapshot and delete the same.

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the **Camera** icon. Alternatively, click the arrow next to the Camera icon and select **Snapshot (default)**.
5. From the Snapshot dialog, select **Perform Snapshot**.
6. Click **View:** under **Timeflow** to verify the Snapshot you just created.
7. To delete, select the snapshot you just created, and from the Actions menu (...) select **Delete Snapshot**.
8. In the Delete Snapshot dialog, select **Delete**.
9. Click **View:** under **Timeflow** to verify the Snapshot, you just deleted.

## Oracle EBS hook operations

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at `/bin/sh`. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a `bash` binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
```

```
# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

## Shell operation tips

### Using `nohup`

You can use the `nohup` command and process backgrounding from resource in order to "detach" a process from the Delphix Engine. However, if you use `nohup` and process backgrounding, you MUST redirect `stdout` and `stderr`.

Unless you explicitly tell the shell to redirect `stdout` and `stderr` in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either `stdout` or `stderr`. Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your `RunCommand` operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad examples

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

#### Good examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs which normally can only be used interactively, such as `ssh`. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Management application and CLI to aid in debugging.

If successful, the script must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

Example of a RunExpect operation

Start an ssh session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
  -re {Password: } {
    send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
  }
  timeout {
    puts "Timed out waiting for password prompt."
    exit 1
  }
}
exit 0
```

### EBS environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set certain environment variables so that the user-provided script can use them to access the dSource or VDB.

#### dSource environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to create the dSource.

#### VDB environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to provision the VDB.

## Delphix architecture with PostgreSQL

### Primer: PostgreSQL replication methodology

Delphix achieves virtualization for the PostgreSQL database through leveraging PostgreSQL's streaming replication protocol between a Primary (parent) and Secondary (child) database configuration. Delphix uses the secondary, hot-standby database as a source database to ingest from.

In a typical PostgreSQL replication workflow, PostgreSQL leverages a parent and child configuration to maintain high-availability with Write Ahead Logs (WAL - a log file where all the modifications to the database are written before they're applied/written to data files) to maintain sync between both databases. This can be seen in the architectural diagram below.

Delphix leverages this feature by capturing the replication stream via file-based log shipping or Streaming WAL records depending on your PostgreSQL configuration. Below is the same PostgreSQL replication architecture diagram with Delphix use case overlaid:

Core concepts:

Write Ahead Logs - WAL:

- These are log files that record all modifications to the database before they're applied/written to data files.

File-Based Log Shipping:

- A method of syncing parent and child databases by applying WAL log files.
- One WAL log file can contain up to 16MB of data
- The WAL file is shipped only after it reaches that threshold
- Note: This will cause a delay in replication and also increase the chances of losing data if the parent crashes and logs are not archived.

Streaming WAL Records:

- WAL record chunks are streamed by database servers to keep data in sync.
- The standby server connects to the parent to receive the WAL chunks.
- The WAL records are streamed as they are generated.
- The streaming of WAL records need not wait for the WAL file to be filled.
- *This allows a standby server to stay more up-to-date than is possible with file-based log shipping.*
- By default, streaming replication is asynchronous even though it also supports synchronous replication.

Delphix supports both methods of ingestion (Log Shipping and Streaming WAL Records). It is important to note that both methods have pros/cons. For example, streaming replication doesn't have as much lag between parent and child, as records are sent as they are generated. However, streaming requires both parent and child to be online and able to communicate directly. It also requires the replica to keep up well enough that the parent still has on-disk copies of the WAL the replica needs, and generally requires you to spend extra `pg_xlog` space on retaining extra WAL for the replica.

## PostgreSQL architecture for streaming replication

Transaction logs - WAL (Write Ahead Logs) - are replayed from source to the staging environment to maintain data sync between the two.

Steps involved in supporting this architectural setup:

1. The end-user application connecting the PostgreSQL source database may perform read/write queries on the database.

2. The database changes are recorded as WAL segments in the PostgreSQL database under the directory **pg\_xlog**.
3. Set up the source PostgreSQL server as Standby Node.
4. Configure replication security by creating a replication user and specifying the authentication protocol.
5. Initiate a base backup on secondary.
6. Configure postgresql.conf file as per the source environment.
7. Start the standby server.

#### **WAL receiver**

The WAL receiver process at the secondary continuously listens for any incoming WAL segments from primary in its receive queue and applies the same on the source database.

#### **WAL segments**

WAL segments are archived when a segment size reaches 16 MB (default).

## Delphix architecture with postgresSQL

This topic describes the high-level process for adding PostgreSQL environments, linking PostgreSQL data sources to the Delphix Engine, and provisioning virtual databases from PostgreSQL data sources.

Given the preceding primer on Streaming Replication and WAL Logs, A high-level breakdown of the PostgreSQL/ Delphix Architecture breaks down as follows:

To match Delphix Terminology the PostgreSQL-denoted parent Host will be referred to as the Source Host and the PostgreSQL-denoted child Host will be referred to as the Staging Host.

For greater detail - Delphix has three ingestion options that leverage a combination of the PostgreSQL Replication Syncing Method as well as backup ingestion initiation:

1. Delphix Initiated Backup Ingestion with PostgreSQL Streaming Replication.
2. Customer Initiated Backup Ingestion with PostgreSQL Streaming Replication.
3. Customer Initiated Backup Ingestion with WAL log Shipping.

Below is a brief breakdown of the pros/cons of the three ingestions options:

Ingestion method	Backup mechanism	Syncing mechanism	Delphix considerations
Delphix Backup + Streaming Replication	The initial backup is taken by Plugin through the <code>pg_basebackup</code> method.	Streaming ensures that source and staging databases are closely synced	This method ensures that Delphix has the capability to ingest as frequently as WAL logs are generated by the Source. This leads to less snapshots than a customer-initiated backup, but those snapshots are aligned to policy.
Customer Backup + Streaming Replication	The initial backup is provided by the customer. Backup is taken through the <code>pg_basebackup</code> method.	Streaming ensures that source and staging databases are closely synced	This method ensures that the Delphix Engine dSource is always closely aligned to the Source Database
Customer Backup + Log Shipping	The initial backup is provided by the customer. Backup is taken through the <code>pg_basebackup</code> method.	The less bandwidth-intensive method which does not require source and staging databases to be directly connected at all times	This method does not require all resources to be concurrent, which leads to a less resource-intensive setup.

## Environment setup

### Linking architecture between PostgreSQL and Delphix Engine

At a high level, the Delphix Engine maintains a logical representation of the source database files, from which one can provision virtual databases (VDBs). In order to link a data source and provision a VDB, the following types of environments are required:

#### PostgreSQL provisioning architecture - source environment - to - Delphix engine

A source environment is where the un-virtualized source database runs. The Delphix Engine uses the backup, restore, and replication features of the PostgreSQL DBMS to maintain its internal representation of the source database, to be used for provisioning VDBs. The Delphix Engine must be able to connect to the source environment in order to discover each running source database and to orchestrate the backup, restore, and replication functionality necessary to keep its representation synchronized with the source database. The Delphix Engine is designed to have a minimal impact on the performance of the source database and the source environment.

#### Target environments for PostgreSQL

A target environment is where virtualized databases run. PostgreSQL target environments serve two purposes:

1. Since PostgreSQL does not provide a native incremental backup API, a warm standby server (in other words, one in log-shipping mode) must be created where all database files are stored remotely on a Delphix Engine. We refer to the process of applying those WAL files to the staging database as validated sync. During validated sync, we retrieve shipped WAL logs from the source, roll the staging database forward, and create a snapshot of that data state.
2. Once a source database has been set up, you can provision virtual databases from any of the discrete snapshots along the Timeflow mentioned above to any compatible target environment (for more information, see [Requirements for PostgreSQL Target Hosts and Databases](#)). Database files are exported over the network to the target environment, where the virtual database instance runs.

## Workflow for PostgreSQL environments

### Linking environments

Prior to linking a data source, both the source environment and a compatible target environment (to be used for the source database mentioned above) must be added to the Delphix Engine. Prior to provisioning a virtual database, a target environment (with similar settings/versioning to the source environment) must be added to the Delphix Engine.

### TARGET HOSTS for PostgreSQL

### Container for VDBs

This topic describes the basic concepts involved with provisioning VDBs from Postgres dSources or even other Postgres VDBs.

Once an environment is added to the Delphix Engine, environment discovery takes place. Environment discovery is the process of enumerating PostgreSQL installations and configurations when a source or target environment is added to the Delphix Engine. The discovery process is repeated during environment refresh in order to detect new PostgreSQL installations and clusters.

A dSource is a copy of a physical database that is created when the Delphix Engine links to and loads the database. The Delphix Engine keeps the dSource in sync with the source database in order to facilitate the provisioning of Virtual Databases (VDBs) from the dSource's TimeFlow. While creating a dsource, the Delphix Engine initiates a full database backup of the source database by running `pg_basebackup` on the source host. The initial snapshot of the dSource is derived from this backup.

After obtaining the initial snapshot and linking the dSource, the Delphix Engine keeps the source and staging database in sync by monitoring the source database for new transaction logs on the source host and then applying those transaction logs on the source database. PostgreSQL streaming replication protocol is used to achieve data replication between the source database and the staging database.

When provisioning a VDB, Delphix creates the database with the default Postgres database options. If the database options have been altered on the source database and you wish for the VDB to reflect these same options, they would need to be altered via a Post-Script or by hook operations.

### Dependencies

If there are dependencies on the snapshot, you will not be able to delete the snapshot free space; the dependencies rely on the data associated with the snapshot.

## Quick start guide for PostgreSQL

### Linking a PostgreSQL data source

This quick start guide, which is excerpted from the larger User Guide, is intended to provide you with a quick overview of working with PostgreSQL database objects in the Delphix Engine. It does not cover any advanced configuration options or best practices, which can have a significant impact on performance. It assumes that you are working in a Lab/Dev setting and attempting to quickly test Delphix functionality. It assumes you will use the VMware Hypervisor.

### Overview

In this guide, we will walk through deploying a Delphix Engine, starting with configuring Source and Target database environment. We will then create a dSource, and provision a VDB.

For purposes of the QuickStart, you can ignore any references to Replication or Masking, such as the engines shown in the diagram below.

### Deploy OVA on VMware

Use the Delphix-supplied OVA file to install the Delphix Engine. The OVA file is configured with many of the minimum system requirements. The underlying storage for the install is assumed to be redundant SAN storage.

1. Download the OVA file from <https://download.delphix.com>. You will need a support login from your sales team or a welcome letter.
  - a. Navigate to the Delphix Product Releases/ /appliance="" images="">
2. Login using the vSphere client to the vSphere server (or vCenter Server) where you want to install the Delphix Engine.
3. In the vSphere Client, click **File**.
4. Select **Deploy OVA Template**.
5. Browse to the OVA file.
6. Click **Next**.
7. Select a **hostname** for the Delphix Engine. This hostname will also be used in configuring the Delphix Engine network.
8. Select the **data center** where the Delphix Engine will be located.
9. Select the **cluster** and the **ESX host**.
10. Select one (1) **data store** for the **Delphix OS**. This datastore can be **thin-provisioned** and must have enough free space to accommodate the 127GB comprising the Delphix operating system.
11. Select four (4) or more **data stores** for Database Storage for the Delphix Engine. The Delphix Engine will stripe all of the Database Storage across these VMDKs, so for optimal I/O performance, each VMDK must be equal in size and be configured **Thick Provisioned - Eager Zeroed**. Additionally, these VMDKs should be distributed as evenly as possible across all four SCSI I/O controllers.
12. Select the **virtual network** you want to use. If using multiple physical NICs for link aggregation, you must use vSphere NIC teaming. Do not add multiple virtual NICs to the Delphix Engine itself. The Delphix Engine should use a single virtual network. For more information, see [Optimal Network Architecture for the Delphix Engine](#)
13. Click **Finish**. The installation will begin and the Delphix Engine will be created in the location you specified.
14. Once the installation has completed, power on the Delphix Engine and proceed with the initial system configuration as described in [Setting Up Network Access to the Delphix Engine](#).

☰ If your source database is 4 TB, you probably need 4 TB of storage for the Delphix Engine. Add at least 4 data disks of similar size for the Delphix VM. For example: for a source database of 4 TB, create 4 VMDKs of 1 TB each.

☰ For a full list of requirements and best practice recommendations, see [Virtual Machine Requirements for VMware Platform](#)

## Setup network access to the Delphix Engine

1. Power on the Delphix Engine and open the Console.
2. Wait for the Delphix Management Service and Delphix Boot Service to come online. This might take up to 10 minutes during the first boot. Wait for the large orange box to turn green.
3. Press any key to access the sysadmin console.
4. Enter `sysadmin@SYSTEM` for the username and `sysadmin` for the password.
5. You will be presented with a description of available network settings and instructions for editing.

Delphix Engine Network Setup To access the system setup through the browser, the system must first be configured **for** networking in your environment. From here, you can configure the primary **interface**, DNS, hostname, and **default** route. When DHCP is configured, all other properties are derived from DHCP settings. To see the current settings, run `"get."` To change a property, run `"set =."` To commit your changes, run `"commit."` To exit **this** setup and **return** to the standard CLI, run `"discard."` defaultRoute IP address of the gateway **for** the **default** route -- **for** example, `"1.2.3.4."` dhcp Boolean value indicating whether DHCP should be used **for** the primary **interface**. Setting **this** value to `"true"` will cause all other properties (address, hostname, and DNS) to be derived from the DHCP response dnsDomain DNS Domain -- **for** example, `"delphix.com"` dnsServers DNS server(s) as a list of IP addresses -- **for** example, `"1.2.3.4,5.6.7.8."` hostname Canonical system hostname, used in alert and other logs -- **for** example, `"myserver"` primaryAddress Static address **for** the primary **interface** in CIDR notation -- **for** example, `"1.2.3.4/22"` Current settings: defaultRoute: `192.168.1.1` dhcp: `false` dnsDomain: `example.com` dnsServers: `192.168.1.1` hostname: `Delphix` primaryAddress: `192.168.1.100/24`

6. Configure the `hostname` . If you are using DHCP, you can skip this step.

```
delphix network setup update *> set hostname=<hostname>
```

**Note:**

Use the same `hostname` you entered during the server installation.

7. Configure DNS. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set dnsDomain=<domain> delphix network setup
update *> set dnsServers=<server1-ip>[,<server2-ip>,...]
```

8. Configure either a static or DHCP address.  
DHCP Configuration

```
delphix network setup update *> set dhcp=true
```

#### Static Configuration

```
delphix network setup update *> set dhcp=false delphix network setup update *>  
set primaryAddress=<address>/<prefix-len>
```

#### Note:

The static IP address must be specified in CIDR notation (for example, 192.168.1.2/24 )

9. Configure a default gateway. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set defaultRoute=<gateway-ip>
```

10. Commit your changes. Note that you can use the `get` command prior to committing to verify your desired configuration.

```
delphix network setup update *> commit Successfully committed network settings.  
Further setup can be done through the browser at: http://<address> Type "exit"  
to disconnect, or any other commands to continue using the CLI.
```

11. Check that you can now access the Delphix Engine through a Web browser by navigating to the displayed IP address, or hostname if using DNS.
12. Exit setup.

```
delphix> exit
```

## Setting up the Delphix Engine

### Virtualization Setup

**Welcome**

Choose engine type to setup:

Virtualization  
 Masking

This wizard will step you through the setup. During this process you will complete the following:

- Create your password for the default "sysadmin" user
- Set the system time
- Configure network and services
- Configure the storage pool
- Configure proxies, SMTP, and LDAP (these are optional)
- Register your software

After setup is complete, you will have two administrators defined:

- The system administrator, "**sysadmin**" with the password you defined. This will be the system administrator for the instance.
- The engine administrator, "**admin**" with the password you defined. This is typically a DBA who will administer all the data managed by the instance.

When setup is complete, log in as engine administrator to begin using your engine.

The setup procedure uses a wizard process to take you through a set of configuration screens:

- Administrators
- Time
- Network
- Network Security
- Storage
- Outbound Connectivity
- Authentication
- Network Authorization
- Registration
- Summary

1. Connect to the Delphix Engine at <http://login/index.html#serverSetup>. The **Delphix Setup** application will launch when you connect to the server. Enter your **sysadmin** login credentials, which initially defaults to the username **sysadmin**, with the initial default password of **sysadmin**. On first login, you will be prompted to change the initial default password.
2. Click **Next**.

### Administrators

The Delphix Engine supports two types of administrators:

- System Administrator (**sysadmin**) - this is the engine system administrator. The sysadmin password is defined here.
- Engine Administrator (**admin**) - this is typically a DBA who will administer all the data managed by the engine.

On the Administrators tab, you set up the sysadmin password by entering an email address and password. The details for the admin are displayed for reference.

**⚠** The default domain user created on Delphix Engines from 5.3.1 is known as **admin** instead of `delphix_admin`. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling `delphix_admin`.

## Time

The engine time is used as the baseline for setting policies that coordinate between virtual databases and external applications

Choose your option to set up system time in this section. For a Quick Start, simply set the time and your timezone. You can change this later.

## Network

The initial out-of-the-box network configuration in the OVA file is set to use a single VMXNET3 network adapter.

You have already configured this in the initial configuration. Delphix supports more advanced configurations, but you can enable those later.

## Storage

You should see the data storage VMDKs or RDMs you created during the OVA installation. Click **Next** to configure these for data storage.

## Serviceability

Choose your options to configure serviceability settings.

For a Quick Start, accept the defaults. You can change this later.

## Authentication service

Choose your options to configure authentication services.

For a Quick Start, accept the defaults. You can change this later.

## Registration

If the Delphix Engine has access to the external Internet (either directly or through a web proxy), then you can auto-register the Delphix Engine:

1. Enter your **Support Username** and **Support Password**.
2. Click **Register**.

If external connectivity is not immediately available, you must perform manual registration.

1. Copy the **Delphix Engine registration code** in one of two ways:
  - a. Manually highlight the registration code and copy it to clipboard. Or,
  - b. Click **Copy Registration Code to Clipboard**.
2. Transfer the Delphix Engine's registration code to a workstation with access to the external network Internet. For example, you could e-mail the registration code to an externally accessible e-mail account.
3. On a machine with access to the external Internet, please use your browser to navigate to the Delphix Registration Portal at <http://register.delphix.com>
4. Login with your Delphix support credentials (username and password).
5. Paste the **Registration Code**.
6. Click **Register**.

- Although your Delphix Engine will work without registration, we strongly recommend that you register each engine as part of the setup. Failing to register the Delphix Engine will impact its supportability and security in future versions.

To regenerate the registration code for a Delphix Engine please refer to, [Regenerating the Delphix Engine Registration Code](#). Delphix strongly recommends that you regenerate this code and re-register the engine regularly to maximize the Support Security of the Delphix Engine. Delphix recommends doing this every six months.

### Summary

The final summary tab will enable you to review your configurations for System Time, Network, Storage, Serviceability, and Authentication.

1. Click the **Back** button to go back and to change the configuration for any of these server settings.
2. If you are ready to proceed, then click **Submit**.
3. Click **Yes** to confirm that you want to save the configuration.
4. Click **Setup** to acknowledge the successful configuration.
5. There will be a wait of several minutes as the Delphix Engine completes the configuration.

## Requirements for PostgreSQL source databases

### Source database requirements

- The Delphix source database can be in READ-WRITE or READ only mode. It can be a standby database(streaming site) as well.
- The Staging host must have access to a PostgreSQL role on the source side that has replication, and login privileges. This can be the built-in PostgreSQL role or a newly-created role (for example, delphix).

```
To create a new role for use with the Delphix Engine, use the following
command: SQL> CREATE USER delphix WITH REPLICATION ENCRYPTED [ PASSWORD
'password'];
```

- You must make the following changes to postgresql.conf (for more information, see the [Server Configuration](#) chapter in the PostgreSQL documentation):
- TCP/IP connectivity must be configured to allow the role mentioned above to connect to the source database from the Delphix Engine and from the standby DBMS instance set up by the Delphix Engine on the staging environment. This can be done by modifying the parameterlisten\_addresses, which specifies the TCP/IP addresses on which the DBMS is to listen for connections from client applications.

```
listen_addresses = '*'           # defaults to 'localhost'; use '*' for all
```

- The value of max\_wal\_senders, which specifies the maximum number of concurrent connections from standby servers or streaming base backup clients, must be increased from its desired value by four. That is, in addition to the allowance of connections for consumers other than the Delphix Engine, there must be an allowance for four additional connections from consumers set up by the Delphix Engine.

```
The default value max_wal_senders is zero, meaning replication is disabled. In
this configuration, the value ofmax_wal_senders must be increased to two for
the Delphix Engine: max_wal_senders = 4           # Default is 0
```

- The value of, `wal_level` which determines how much information is written to the write-ahead log (WAL), must be set to `archive` or `hot_standby` to allow connections from standby servers. The value `logical_wal_level` (introduced in PostgreSQL 9.4) is also supported.

The **default** value of `wal_level` is `minimal`, which writes only the information needed to recover from a crash or immediate shutdown to the WAL archives. In **this** configuration, you must add the logging required **for** WAL archiving as follows:

```
wal_level = archive          # Default is minimal
```

- In releases prior to PostgreSQL 9.6.x, parameter 'wal\_level' allowed the values 'archive' and 'hot\_standby'. These values are still accepted but mapped to 'replica'. For example, The plugin will work with `ALTER SYSTEM SET wal_level TO 'replica'` and `ALTER SYSTEM SET wal_level TO 'hot_standby'`.
- You must configure PostgreSQL to allow PostgreSQL client connections and replication client connections from the staging target environment. To configure appropriately, add the following entries to `pg_hba.conf`:

```
host all <role> <ip-address_of_delphix_engine>/32 <auth-method> host all <role>
<ip-address_of_staging_target>/32 <auth-method> host replication <role> <ip-
address_of_staging_target>/32 <auth-method>
```

- `<auth-method>` can be set to `trust`, `scram-sha-256`, or `md5` on source. Delphix inherits the same authentication method from the source while dSource creation and VDB provisioning. For more information on how to configure, `pg_hba.conf` see the [Client Authentication](#) chapter in the PostgreSQL documentation.
- `wal_keep_segments` parameter in `postgresql.conf` file on the Source environment should be large enough to support the WAL sync process once the dSource is building up. Postgres 13 onwards, the configuration parameter `wal_keep_segments` is changed to `wal_keep_size`. It is specified in megabytes rather than the number of files as with the `wal_keep_segments` parameter. If you previously used `wal_keep_segments`, the following formula will give you an approximate equivalent setting: `wal_keep_size = wal_keep_segments * wal_segment_size` (typically 16MB).
- It is mandatory to have "port" (can be commented or not commented) in `postgresql.conf` file.

## Requirements for PostgreSQL target hosts and databases

### Target environment requirements

1. The operating system and architecture of the target environment must match those of the source environment. It is recommended that the source and the target environments should be identical and hardware configurations should match.
2. For supported OS version and DBMS version, see [PostgreSQL Matrix](#). The underlying Operating System for both the Source and Staging environment should be amongst these two versions.
3. There must be an installation of PostgreSQL on the target environment that is compatible with the installation of PostgreSQL on the source environment. Two installations of PostgreSQL are compatible if and only if:
  - a. They share the same vendor (for example, PostgreSQL is incompatible with EnterpriseDB Postgres Plus Advanced Server).
  - b. They share the same major version number (for example, 9.5.4 is compatible with 9.5, 9.5.3; however, it is incompatible with 9.3, 9.3.24, or 9.2).
  - c. They are compiled against the same architecture (in other words, 32-bit and 64-bit installations of Postgres are incompatible).

- d. They are compiled with the same WAL segment size. The default WAL segment size of 16 MB is rarely changed in practice, so almost all installations of PostgreSQL are compatible with each other in terms of WAL segment size.
4. There must be an operating system user (e.g. PostgreSQL) with the following privileges:
  - a. The Delphix Engine must be able to make an SSH connection to the target environment using the operating system user.
  - b. The operating system user must have read and execute privileges on the PostgreSQL binaries installed on the target environment.
  - c. The operating system user must have permission to run mount and umount as the superuser via sudo with neither a password nor a TTY. See [Sudo Privilege Requirements for PostgreSQL Environments](#) for examples of the /etc/sudoers file on different operating systems.
5. There must be a directory on the target environment where the Delphix Engine Plugin can be installed (for example, /var/tmp ) with the following properties:
  - a. The Plugin directory must be writable by the operating system user mentioned above.
  - b. The Plugin directory must have at least 1.5 GB of available storage.
6. There must be a mount point directory (for example, /mnt) that will be used as the base for mount points that are created when provisioning a VDB with the following properties:
  - a. The mount point directory must be writable by the operating system user mentioned above.
  - b. The mount point directory should be empty.
7. TCP/IP connectivity to and from the source environment must be configured as described in General Network and Connectivity Requirements.
8. Hostname and IP must be correctly set in /etc/hosts file, for example [postgres@source ~]\$ hostname -i  
The output of “hostname -i” command should produce the correct result as the IP address of the server. For example:  
[postgres@source postgres]\$ hostname -i 10.110.207.113
9. When using the External Backup method for ingestion the directories being used for keeping the Backup file and WAL file should be accessible by OS User.
10. Zip must be installed on the Staging/Target Host for External Backup Support.
11. The backup command and File should be in the below format: PostgreSQL\_T<YYYYMMDD>.zip where YYYY denotes Year, MM denotes month, DD denotes date. For example PostgreSQL\_T20190314.zip. The above zip file should contain a Database Full Backup from the Source created in tar format. The below flags can be used with pg\_basebackup for taking Source Database backup: **For PostgreSQL versions 9.4.x, 9.5.x, and 9.6.x** <PATH\_TO\_PG\_BIN>/pg\_basebackup -p<PORT>-D<EMPTY\_BACKUP\_DIR>-F t -v -w -P -x**For PostgreSQL versions 10.x and 11.x** <PATH\_TO\_PG\_BIN>/pg\_basebackup -p <PORT> -D <EMPTY\_BACKUP\_DIR> -F t -v -w -P -Xs
12. If there's no PostgreSQL instance running on the Target host, however, we have a PostgreSQL installation, even then the plugin relies on the "DELPHIX\_PG\_PATH" variable to discover the environment. In the absence of "DELPHIX\_PG\_PATH" variable or if the value of "DELPHIX\_PG\_PATH" variable is NULL then Linux "find" command will be used for the Environment discovery which may impact the overall performance. Hence, it is preferred to create this Environment Variable with correct entries. In order to optimize the performance, it is preferred to create an Environment Variable "DELPHIX\_PG\_PATH" which should be accessible by OS users. Below should be the syntax for "DELPHIX\_PG\_PATH" variable:  
DELPHIX\_PG\_PATH="binary\_path:data\_path1;binary\_path:data\_path2;"  
For example: DELPHIX\_PG\_PATH="/usr/pgsql-9.6/bin:/var/lib/pgsql/9.6/data;/opt/edb/as9.6/bin:/opt/edb/as9.6/data;/usr/pgsql-9.6/bin:/tmp/TESING/data;"

 The variable "**DELPHIX\_PG\_PATH**" must be available to the environment user in a non-interactive way. You can test this variable for non-interactive logins using `ssh your_username@v-cardtr.tmydb.kv.aval "env | grep DELPHIX_PG_PATH"`.

## Adding a PostgreSQL environment

### Prerequisites

- Make sure that the staging environment in question meets the requirements described in [Requirements for PostgreSQL Hosts and Databases](#) and Prerequisites for Discovery operation described in the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) section.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next, to Environments, click the Actions (...) menu and select **Add Environment**.
5. In the Add Environment dialog, select **Unix/Linux**.
6. Select **Standalone Host**.
7. Click **Next**.
8. Enter Name for the Environment.
9. Enter the **Host IP address** or **hostname**.
10. Enter the **SSH port**. The default value is 22.
11. Enter an **OS Username** for the Environment. If a low-privileged OS user is used, make sure the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) are met.
12. Select **Login Type**. — Username and Password - enter the OS username and password — Username and Public Key - enter the OS username. — Password Vault - select from an existing Enterprise Password Vault

#### Info:

#### Using Public Key Authentication

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

- a. Select **Public Key** for the **Login Type**.
- b. Click **View Public Key**.
- c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See Option 2 in [this CLI Cookbook article](#) for instructions.

13. For Password, enter the password associated with the user in step 11.
14. If you want to use Public Key Encryption for logging into your environment:
  - a. Select Public Key for the Login Type.
  - b. Click View Public Key.
  - c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
    - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
    - ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.

- iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.  
The public key needs to be added only once per user and per environment.  
You can also add public key authentication to an environment user's profile by using the command-line interface, as explained in the topic [CLI Cookbook: Setting Up SSH Key Authentication for UNIX Environment Users](#)
15. For Password Login, click Verify Credentials to test the username and password.
16. Enter **Toolkit Path** (make sure Toolkit path does not have spaces).
17. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
18. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
19. Click **Submit**.

As the new environment is added, you will see two jobs running in the Delphix platform Job History, one to Create and Discover an environment, and another to create an environment. When the jobs are complete, you will see the new environment added to the list in the Environments tab. If you do not see it, click the Refresh icon in your browser.

Once the environment is discovered, further linking would require adding a source config to the above-discovered installation. Please refer to [Linking a PostgreSQL dSource](#) for more information.

## Linking a PostgreSQL data source

### Prerequisites

- The source and staging instances must meet the host requirements
- Databases must meet container requirements. For more information refer to [Requirements for PostgreSQL Source Hosts and Databases](#)

### Limitation

It is not possible to access the staging server with PostgreSQL 9.4 and PostgreSQL 9.5 versions.

### Procedure

1. Login to the **Delphix Management** application.
2. Select **Manage > Environments**.
3. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.
4. In the **Add Database** dialog window enter the **Name** for your source config and click **Add**.
5. Select your source config and click the **Add dSource** link located to the right.
6. In the **Source** tab, do the following:

**Data Type**

AppData

NFS Mount Location \*

`/tmp/dSource`

Mount Location on Staging Host [No spaces allowed]

Privileged OS Account (Optional)

postgres

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation.  
 Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

**External Backup**

dSource Creation through external backup

**+ Add** **Delphix Initiated Backup - Postgres Cluster Ingestion Flag**

Allow Delphix to initiate the physical backup on source database. "Streaming Replication Parameters" are mandatory for ingestion.

**Delphix Initiated Backup/External Backup - Streaming Replication Parameters**

List of parameters for Delphix initiated backup and external backup with streaming replication

**+ Add**

- In the **NFS Mount Location** field, enter a mount location on the staging host.
- If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) section

**Info:**

You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.

If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

- access to the the postgres commands
  - read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]
- Select the checkbox next to the **Delphix Initiated Backup - Postgres Cluster Ingestion Flag** option. Selecting this checkbox allows Delphix to initiate the physical backup on the source database.
  - Click on the **+Add** icon located next to the **Delphix Initiated Backup/External Backup - Streaming Replication Parameters** option.

**Note:**

The Add Button provided for Delphix Initiated Backup/External Backup - Streaming Replication is clickable multiple times but should be used **ONLY** once since the solution is built only to support a single backup path. Providing Multiple Paths will error out the linking process.

The following fields are mandatory for this process :

- Delphix Initiated Backup - Postgres Cluster Ingestion Flag - Checkbox should be selected.

- ii. **PostgresDB Replication User**
- iii. **PostgresDB Replication User Password**
- iv. **Source Host Address**
- v. **Source Instance Port Number**
- vi. **Staging Instance Port Number** - must be unique for a given instance.

Privileged OS Account (Optional)

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation.  
Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

## External Backup

dSource Creation through external backup

+ Add

Delphix Initiated Backup - Postgres Cluster Ingestion Flag

Allow Delphix to initiate the physical backup on source database. "Streaming Replication Parameters" are mandatory for ingestion.

## Delphix Initiated Backup/External Backup - Streaming Replication Parameters

List of parameters for Delphix initiated backup and external backup with streaming replication

PostgresDB Replication User \*

delphix

Delete

Replication User for Postgres database

PostgresDB Replication User Password \*

\*\*\*\*\*

Replication password for Postgres database

Source Host Address \*

centos78pg12src.dlpxdc.co

Source Host Address

Source Instance Port Number \*

5432

Port number for Postgres source database

+ Add

- e. Optionally, database configuration parameters can be defined during the linking operation in the **Config Settings** section.

## Config Settings

Custom Database-Level config settings

Property Name \*

 Delete

Value

Comment Property

Select this option to comment out the provided property name in the configuration file

 Add

### Note:

After dSource creation, users can now configure the parameters and their values in the `postgresql.conf` file through the "Config Settings" section on the Delphix Engine UI. For example, to support **Replication Slots** through UI, users can now provide the "primary\_slot\_name" parameter and its value through the UI. This will update the already existing parameter value in the `postgresql.conf` file with the value provided by the user.

Similarly, if a user wants to disable a parameter then they can provide the parameter name and select the check box **Comment Property**. This will comment out the parameter in the `postgresql.conf` configuration file.

- f. Click **Next**.
7. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
8. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
9. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
10. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
11. In the **Summary** tab, review the configuration profile for the dSource.
12. Click **Submit**. The Delphix Engine initiates two jobs to create the dSource: DB\_Link and DB\_Sync. You can monitor these jobs by clicking **Active Jobs** from the top menu bar, or by selecting **System > Event Viewer**. When the jobs have successfully completed, the database icon will change to a dSource icon on the **Environments > Host > Databases** screen, and the dSource will also appear in the list of Datasets under its assigned group.

### Note:

[The dSource Configuration Screen](#)

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to

examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations.

## Provisioning a PostgreSQL VDB

### Prerequisites

- You will need to have linked a dSource from a staging instance, as described in [Linking a PostgreSQL dSource](#) or have created a VDB from which you want to provision another VDB
- You should have set up the POSTGRES target environment with the necessary requirements as described in [PostgreSQL Support and Requirements](#)
- Make sure you have the required Instance Owner permissions on the target instance and environment
- The method for [Database Permissions for Provisioned PostgreSQL VDBs](#) is decided before the provisioning

### Procedure

1. Navigate to **Manage**, and select **Datasets**.
  2. Select a dSource and a snapshot from which you want to provision. Click the provision VDB icon to open the **provision VDB** wizard.
  3. Select a target environment from the left pane, and an Installation to use from the dropdown list of available PostgreSQL instances on that environment.
  4. Set the **Environment User** to be the Instance Owner.
- Note:**  
 The picking of instance owner is only possible if you have multiple environment users set on that host.
5. You will see the **Target Configuration** section where you need to specify **NFS Mount Location**.

#### Provision Plugin-based VDB

The screenshot shows a wizard interface for provisioning a VDB. On the left, a vertical progress bar has six steps: Target Environment, Target Configuration (selected), Configuration, Policies, Masking, Hooks, and Summary. The main content area is titled 'Target Configuration' and includes the instruction 'Configure the target environment.' It features three input fields: 'NFS Mount Location \*' with the value '/tmp/vdb', 'Privileged OS Account (Optional)', and 'Virtual Postgres Port Number \*' with the value '5434'. Below these are two sections: 'VDB PiT with External Logs Details' and 'Config Settings', each with a '+ Add' button.

6. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisite for Discovery Operation](#) section.

**Note:**

To update the Privileged OS Account after VDB creation, first disable the instance, update the Privileged OS Account, and then enable it.

If the Environment OS user will be used to create the VDB, make sure you have the following privileges:

- [access to the the postgres commands](#)
  - [read+write+execute permissions on the `unix\\_socket\\_directories` configured in `postgresql.conf` \[Default directories: `/var/run/postgresql` & `/tmp`\]](#)
7. Optionally, you can set the database configuration parameters for the VDB using **Config Settings**. Users can disable a configuration parameter by selecting the check box Comment Property. This will comment out the parameter in the `postgresql.conf` configuration file. Click **Next**.

### Config Settings

Custom Database-Level config settings

Property Name *	ssl	Delete
Value	off	
<input type="checkbox"/> Comment Property		
<small>Select this option to comment out the provided property name in the configuration file</small>		
Property Name *	listen_addresses	Delete
Value		
<input checked="" type="checkbox"/> Comment Property		
<small>Select this option to comment out the provided property name in the configuration file</small>		
<span style="border: 1px solid #ccc; padding: 5px 15px;">+ Add</span>		

8. On the **Configuration** page enter the PostgreSQL VDB name which will be displayed on the UI.
9. Select a **Target Group** for the VDB and click the green **Plus** icon to add a new group, if necessary.
10. Select a **Snapshot Policy** for the VDB then click **Next**.
11. Specify any desired hook operations.
12. Review the Provisioning Configuration and Data Management information.
13. Click **Submit**.

Once the VDB provisioning has successfully completed, if the source and target instance ids are not the same, you may want to grant secadm and dbadm on the database to the target instance id. Please refer to [Database Permissions for Provisioned PostgreSQL VDBs](#) for more information.

### Next steps

Congratulations! You have provisioned your first virtual database!

Now, perform some simple functional tests with your application. You can connect your app to the VDB using standard TNS/JDBC techniques. Delphix has already registered the VDB for you on the target listener.

We suggest the following next steps:

1. Drop a table and use the VDB Rewind feature to test the recovery of your VDB.
2. Take a snapshot of your dSource and refresh your VDB to quickly get fresh production data.
3. Provision a new VDB from your VDB to test the sharing data quickly with other teams.
4. Mask your new VDB to protect sensitive data. Provision new VDBs from that masked VDB to quickly provide safe data to development and QA teams.

## PostgreSQL plugin installation

The Plugin is provided as a zip file in the Delphix download site. Follow below steps to download plugin:

1. In the web browser, go to the Delphix [download](#) site.
2. Login to the download site using email and password credentials.
3. Navigate to the required version number of Delphix Engine.
4. Go to the Plugins > PostgreSQL > Plugin\_<version\_number>.zip folder and download the zip file.

Refer to the section [Delphix Engine Plugin Management](#) for further details.

## PostgreSQL support and requirements

In order to begin using PostgreSQL environments with Delphix, you will need to configure the source and target hosts with the requirements described in this section.

This section covers the following topics:

- [PostgreSQL compatibility matrix](#)
- [Requirements for PostgreSQL hosts and databases](#)
- [Network and connectivity requirements for PostgreSQL environments](#)
- [Sudo privilege requirements for PostgreSQL environments](#)
- [Sudo file configuration examples for PostgreSQL environments](#)
- [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#)

### PostgreSQL compatibility Matrix

Delphix Support Policies specifically list Major and Minor release coverage. If a minor release is listed as covered, then all patch releases under that minor release are certified.

**Key:**

Color	Supported?
Y	Yes
N	No

RHEL/CentOS/SUSE/Ubuntu

Support ed OS Version	9.4.x (Open Source & EDB)	9.5.x (Open Source & EDB)	9.6.x (Open-source & EDB)	10.x (Open-source & EDB)	11.x (Open-source & EDB)	12.x (Open-source & EDB)	13.x (Open-source & EDB)	14.x (Open-source & EDB)	15.x (Open-source & EDB)
	Supported DBMS Version								
RHEL/ CentOS 7.3	Y	Y	Y	Y	Y	Y	N	N	N
RHEL/ CentOS 7.4	Y	Y	Y	Y	Y	Y	N	N	N
RHEL/ CentOS 7.5	Y	Y	Y	Y	Y	Y	N	N	N
RHEL/ CentOS 7.6	Y	Y	Y	Y	Y	Y	N	N	N
RHEL/ CentOS 7.7	Y	Y	Y	Y	Y	Y	N	N	N
RHEL/ CentOS 7.8	Y	Y	Y	Y	Y	Y	N	N	N

RHEL 7.9	N	N	Y	Y	Y	Y	Y	Y	N
CentOS 7.9	N	N	N	N	N	Y	Y	Y	N
RHEL 8.3	N	N	N	N	N	Y	Y	Y	N
RHEL 8.6	N	N	N	N	N	Y	Y	Y	Y
SUSE 11	Y	N	N	N	N	N	N	N	N
SUSE 12	Y	Y	Y	Y	Y	N	N	N	N
SUSE 15	N	N	N	N	N	N	Y	N	N
Ubuntu 16.04	N	N	N	Y	N	N	N	N	N
SUSE 15SP3	N	N	N	N	N	N	N	N	N

where **x** represents the minor version.

- All the available PostgreSQL Database minor versions will be supported for the above-mentioned major versions.
- SUSE 15SP3 is supported on Power 8 hardware.
- Make sure to install libncurses.5 or libncurses.6 in the host, for supporting RHEL 8.x and SUSE15. You can refer [KBA 5622](#) for actionable steps.

Cloud vendors

Supported Cloud Vendors	PostgreSQL 11	PostgreSQL 12	PostgreSQL 13
Amazon RDS PostgreSQL	Y	Y	Y
Amazon Aurora PostgreSQL	Y	Y	Y

For this release, only a single DB ingestion feature is supported for the Amazon RDS/Aurora PostgreSQL through the pg\_dump/pg\_restore method.

Plugin/Delphix engine compatibility

Plugins should be installed on compatible Delphix Engines per the table below:

Currently, PostgreSQL Plugin 1.4.1 is not supported on SUSE 12.x.

Delp hix Engi ne Vers ion	Plugin Version												
	1.4.0	1.4.1	1.4.2	1.4.3	1.4.4	1.5.0	1.5.1	2.0.0	2.1.0	2.1.1	3.0.0	3.1.0	3.2.0
6.0.0.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.1.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.2.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.3.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.4.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.5.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.6.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.7.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.8.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.9.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.10.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N

6.0.1 1.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.1 2.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N
6.0.1 3.x	Y	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N

10.0. 0.x	N	N	N	N	N	N	N	N	N	N	N	N	N

Unsupported PostgreSQL versions and features

- PostgreSQL versions below 9.4 i.e (9.2, 9.3) are NOT supported by the plugin.
- It is not possible to access the staging server with PostgreSQL 9.4 and PostgreSQL 9.5 versions. The following points describe why staging server is not accessible with PostgreSQL 9.4 and PostgreSQL 9.5 versions.
  - a. On staging server, PostgreSQL plugin setups warm standby till version 9.x, which indicates that you cannot access PostgreSQL database on staging instance with PostgreSQL 9.4 and PostgreSQL 9.5 versions or even dsource for READ-ONLY workload. However, in later versions it is possible to trigger READ-ONLY query on dsource.
  - b. In PostgreSQL version 9.x, the plugin sets *wal\_level* parameter on staging server PostgreSQL instance to *archive*. However for PostgreSQL version 10 and later, PostgreSQL plugin sets *wal\_level* parameter

on staging server PostgreSQL instance to *hot\_standby* or *replica*.

**Info**

- **Warm Standby/Log Shipping** is a HA solution which 'replicates' a database cluster to an archive or a warm (can be brought up quickly, but not available for querying) standby server. Overhead is very low and it's easy to set up. This is a simple and appropriate solution if all you care about is continuous backup and short failover times.
- **Hot Standby/Streaming Replication** provides asynchronous binary replication to one or more standbys. Standbys may also become hot standbys meaning they can be queried as a read-only database. This is the fastest type of replication available as WAL data is sent immediately rather than waiting for a whole segment to be produced and shipped. In *hot\_standby* level, the same information is logged as with archive, plus information needed to reconstruct the status of running transactions from the WAL. To enable read-only queries on a standby server, *wal\_level* must be set to 'hot\_standby' or higher on the primary, and *hot\_standby* must be enabled in the standby.  
 Dsource created in PostgreSQL 9.4 & 9.5 version is a warm standby so it is not accessible. *wal\_level* determines how much information is written to the WAL. The default value is minimal, which writes only the information needed to recover from a crash or immediate shutdown. *archive* adds logging required for WAL archiving; *hot\_standby* further adds information required to run read-only queries on a standby server; and, finally *logical* adds information necessary to support logical decoding. Each level includes the information logged at all lower levels. This parameter can only be set at server/instance level.
- There are two features that are not supported by the plugin:
  - a. Unlogged Tables: All the tables which are not logged (unlogged) will not be supported by the Plugin.
  - b. Point In Time recovery: Currently, the Plugin doesn't support Point in Time recovery of the PostgreSQL database.

## Requirements for PostgreSQL hosts and databases

In order to begin using PostgreSQL environments with Delphix, you will need to configure the source and target with the requirements described on this page.

### PostgreSQL hosts and databases

On each host with Postgres, there must be an operating system user configured to the required specifications for Delphix, as explained in the table below. These requirements apply to both source and target environments. However, target environments have additional requirements which are detailed in the [Target Host Requirements](#) section below.

 The PostgreSQL plugin requires the use of the default user which gets created during the Postgres DB installation process. Usually, 'postgres'. In case you want to use a low-privileged OS user to add the environment and create datasets with the same, make sure that the additional requirements for Privilege elevation are met, see [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#)

### Source database requirements

Database Requirement	Explanation
<p>The source database can be in READ-WRITE or READ-only mode. It can be a standby database(streaming site) as well.</p>	
<p>The Staging host must have access to a PostgreSQL role on the source side that has replication, and login privileges. This can be the built-in PostgreSQL role or a newly-created role (for example, delphix).</p>	<p><b>Creating a Role for Use with the Delphix Engine</b></p> <p>To create a new role for use with the Delphix Engine, use the following command:</p> <pre style="border: 1px solid #ccc; padding: 5px;">SQL&gt; CREATE USER delphix WITH REPLICATION ENCRYPTED [ PASSWORD 'password'];</pre>

Database Requirement	Explanation
<p>You must make the following changes to postgresql.conf:</p> <p>modifying the parameter <code>listen_addresses</code>, which specifies the TCP/IP addresses on which the DBMS is to listen for connections from client applications.</p>	<p><b>Note:</b> TCP/IP connectivity must be configured to allow the role mentioned above to connect to the source database from the Delphix Engine and from the standby DBMS instance set up by the Delphix Engine on the staging environment.</p> <p><b>listen_addresses configuration</b></p> <p>The simplest way to configure PostgreSQL is so that it listens on all available IP interfaces:</p> <pre>listen_addresses = '*'      # Default is 'localhost'</pre> <p>(for more information, see the <a href="#">Server Configuration</a> chapter in the PostgreSQL documentation)</p>
<p>The value of <code>max_wal_senders</code>, which specifies the maximum number of concurrent connections from standby servers or streaming base backup clients, must be increased from its desired value by two. That is, in addition to the allowance of connections for consumers other than the Delphix Engine, there must be an allowance for two additional connections from consumers set up by the Delphix Engine.</p>	<p><b>max_wal_senders Configuration</b></p> <p>The default value <code>max_wal_senders</code> is zero, meaning replication is disabled. In this configuration, the value of <code>max_wal_senders</code> must be increased to two for the Delphix Engine:</p> <pre>max_wal_senders = 2      # Default is 0</pre>
<p>The value of, <code>wal_level</code> which determines how much information is written to the write-ahead log (WAL), must be set to <code>archive</code> or <code>hot_standby</code> to allow connections from standby servers. The value "logical" for <code>wal_level</code> (introduced in PostgreSQL 9.4) is also supported.</p> <p>In releases prior to PostgreSQL 9.6.x, parameter 'wal_level' allowed the values 'archive' and 'hot_standby'. These values are still accepted but mapped to 'replica'.</p> <p>For example, The plugin will work with ALTER SYSTEM SET wal_level TO 'replica' and ALTER SYSTEM SET wal_level TO 'hot_standby'.</p>	<p><b>wal_level Configuration</b></p> <p>The default value of <code>wal_level</code> is minimal, which writes only the information needed to recover from a crash or immediate shutdown to the WAL archives. In this configuration, you must add the logging required for WAL archiving as follows:</p> <pre>wal_level = archive      # Default is minimal</pre>

Database Requirement	Explanation
<p>You must configure PostgreSQL to allow PostgreSQL client connections and replication client connections from the staging target environment.</p>	<p>To configure appropriately, add the following entries to pg_hba.conf:</p> <pre data-bbox="798 454 1425 824"> pg_hba.conf Configuration host all &lt;role&gt; &lt;ip-address_of_delphix_engine&gt;/32 &lt;auth-method&gt; host all &lt;role&gt; &lt;ip-address_of_staging_target&gt;/32 &lt;auth-method&gt; host replication &lt;role&gt; &lt;ip-address_of_staging_target&gt;/32 &lt;auth-method&gt; </pre>
<p>&lt;auth-method&gt; can be set to trust, scram-sha-256, or md5 on source. Delphix inherits the same authentication method from the source while dSource creation and VDB provisioning. For more information on how to configure, pg_hba.conf see the <a href="#">Client Authentication</a> section in the PostgreSQL documentation.</p>	
<p><code>wal_keep_segments</code> parameter in postgresql.conf file on the Source environment should be large enough to support the WAL sync process once the dSource is building up.</p> <p>Postgres 13 onwards, the configuration parameter <code>wal_keep_segments</code> is changed to <code>wal_keep_size</code>. It is specified in megabytes rather than the number of files as with the <code>wal_keep_segments</code> parameter. If you previously used <code>wal_keep_segments</code>, the following formula will give you an approximate equivalent setting:</p> $\text{wal\_keep\_size} = \text{wal\_keep\_segments} * \text{wal\_segment\_size} \text{ (typically 16MB).}$	
<p>It is mandatory to have "port" (can be commented or not commented) in postgresql.conf file.</p>	

## Target Host Requirements

Host Requirement	Explanation
The operating system and architecture of the target environment must match those of the source environment.	It is recommended that the source and the target environments should be identical and hardware configurations should match.
Compatible Operating System supported by the Plugin is CentOS 7.3/7.4/7.5/7.6/7.7/7.8/7.9 and RHEL 7.3/7.4/7.5/7.6/7.7/7.8/7.9/8.3/8.6.	The underlying Operating System for both the Source and Staging environment should be among these versions.
There must be an installation of PostgreSQL on the target environment that is compatible with the installation of PostgreSQL on the source environment.	<p>Two installations of PostgreSQL are compatible if and only if:</p> <ol style="list-style-type: none"> <li>1. They share the same vendor (for example, PostgreSQL is incompatible with EnterpriseDB Postgres Plus Advanced Server).</li> <li>2. They share the same major version number (for example, 9.5.4 is compatible with 9.5, 9.5.3; however, it is incompatible with 9.3, 9.3.24, or 9.2).</li> <li>3. They are compiled against the same architecture (in other words, 32-bit and 64-bit installations of Postgres are incompatible).</li> <li>4. They are compiled with the same WAL segment size. The default WAL segment size of 16 MB is rarely changed in practice, so almost all installations of PostgreSQL are compatible with each other in terms of WAL segment size.</li> </ol>
<p>There must be an operating system user (e.g Postgres) with the following privileges:</p> <ol style="list-style-type: none"> <li>1. The Delphix Engine must be able to make an SSH connection to the target environment using the operating system user.</li> <li>2. The operating system user must have read and execute privileges on the PostgreSQL binaries installed on the target environment.</li> <li>3. The operating system user must have permission to run mount and unmount as the superuser via sudo with neither a password nor a TTY.</li> </ol>	See <a href="#">Sudo Privilege Requirements for PostgreSQL Environments</a> for further explanation of the commands, and <a href="#">Sudo File Configuration Examples for PostgreSQL Environments</a> for examples of the /etc/sudoers file on different operating systems.

Host Requirement	Explanation
<p>There must be a directory on the target environment where the Delphix Engine Plugin can be installed (for example, /var/tmp ) with the following properties:</p> <ol style="list-style-type: none"> <li>1. The Plugin directory must be writable by the operating system user mentioned above.</li> <li>2. The Plugin directory must have at least 1.5 GB of available storage.</li> </ol>	
<p>There must be a mount point directory (for example, /mnt) that will be used as the base for mount points that are created when provisioning a VDB with the following properties:</p> <ol style="list-style-type: none"> <li>1. The mount point directory must be writable by the operating system user mentioned above.</li> <li>2. The mount point directory should be empty.</li> </ol>	
<p>TCP/IP connectivity to and from the source environment must be configured as described in General Network and Connectivity Requirements.</p>	
<p>Hostname and IP must be correctly set in /etc/hosts file, for example [postgres@source ~]\$ hostname -i</p>	<p>The output of “hostname -i” command should produce the correct result as the IP address of the server.</p> <p>For example:</p> <pre data-bbox="791 1256 1425 1375">[postgres@source postgres]\$ hostname -i 10.110.207.113</pre>
<p>When using the External Backup method for ingestion the directories being used for keeping Backup file and WAL file should be accessible by OS User.</p>	
<p>Ensure that either the <code>netstat</code> or <code>ss</code> utility is installed on the Staging/Target Host.</p>	<p>Checking if <b>netstat</b> utility is installed:</p> <pre data-bbox="791 1648 1425 1733">which netstat</pre> <p>Checking if <b>ss</b> utility is installed:</p> <pre data-bbox="791 1798 1425 1883">which ss</pre>

Host Requirement	Explanation
Zip must be installed on the Staging/Target Host for External Backup Support.	Checking if <b>zip</b> utility is installed: <div data-bbox="791 421 1423 539" style="border: 1px solid black; padding: 5px; margin-top: 10px;">which zip # or which unzip</div>

Host Requirement	Explanation
<p>From PostgreSQL Plugin 3.2.0 onwards, the backups can be provided in three ways:</p> <ol style="list-style-type: none"> <li>1. Database full Backup in tar format can be placed inside organized folders named <b>PostgreSQL_T&lt;YYYYMMDDhhmmss&gt;</b>, created within the backup path. For example, <b>PostgreSQL_T20230224033939</b>.</li> <li>2. Database full Backup in tar format can be directly placed within the backup path. 3. Providing the full backup encapsulated in a ZIP file in the format <b>PostgreSQL_T&lt;YYYYMMDD&gt;.zip</b> (supported by previous plugin versions). Make sure that the backup files are available directly at the root level of the ZIP.</li> <li>3. Providing the full backup encapsulated in a ZIP file in the format <b>PostgreSQL_T&lt;YYYYMMDD&gt;.zip</b> (supported by previous plugin versions). Make sure that the backup files are available directly at the root level of the ZIP. For example, <b>PostgreSQL_T20230224.zip</b>.</li> </ol> <p><b>Precedence Rules:</b></p> <ul style="list-style-type: none"> <li>• When all types of backups are provided within the same backup path, the plugin will choose the organized folders over other backups. The backup stored in organized folders has the highest precedence.</li> <li>• If backups are placed directly within the backup path and the ZIP files are also present, the plugin will choose the direct backups over ZIP files.</li> <li>• The ZIP files have the least precedence in the hierarchy of all backup types.</li> </ul> <p><b>Note:</b> YYYY denotes year, MM denotes month, DD denotes date, hh denotes hours, mm denotes minutes and ss denotes seconds.</p>	<p>Useful commands:</p> <pre data-bbox="794 421 1423 1400"> # For method 1 DLPXPGBACKUPDIR=&lt;backup_path&gt;/ PostgreSQL_T\$(date "+%Y%m%d%H%M%S") mkdir -p \$DLPXPGBACKUPDIR  # For method 2 &amp; 3 DLPXPGBACKUPDIR=&lt;path_to_empty_directory&gt; mkdir -p \$DLPXPGBACKUPDIR  # For PostgreSQL versions 9.4.x,9.5.x,9.6.x &lt;path_to_bin&gt;/pg_basebackup -D \$DLPXPGBACKUPDIR -F t -v -w -P -x [-h &lt;source_ip_domain_name&gt;] [-p &lt;source_port&gt;] [-U &lt;source_user&gt;]  # For PostgreSQL versions 10.x and above &lt;path_to_bin&gt;/pg_basebackup -D \$DLPXPGBACKUPDIR -F t -v -w -P -Xs [-h &lt;source_ip_domain_name&gt;] [-p &lt;source_port&gt;] [-U &lt;source_user&gt;]  # For method 3, zipping the backup cd \$DLPXPGBACKUPDIR DLPXPGBACKUPZIP=PostgreSQL_T\$(date +"%Y%m%d").zip zip \$DLPXPGBACKUPZIP *</pre> <p>Checking if backups are available at the root of the ZIP file:</p> <pre data-bbox="794 1496 1423 1865"> # As an example # The backup files are available at the root of the ZIP file \$ zipinfo PostgreSQL_T20230224.zip Archive:  PostgreSQL_T20230224.zip Zip file size: 6883130 bytes, number of entries: 5 -rw-----  3.0 unx  9093632 bx defN 23-Feb-24 02:12 24578.tar -rw-----  3.0 unx  9093632 bx defN 23-Feb-24 02:12 24579.tar</pre>

Host Requirement	Explanation
	<pre>-rw----- 3.0 unx 9093632 bx defN 23- Feb-24 02:12 24580.tar -rw----- 3.0 unx 26959360 bx defN 23- Feb-24 02:12 base.tar -rw----- 3.0 unx 16778752 bx defN 23- Feb-24 02:12 pg_wal.tar 5 files, 71019008 bytes uncompressed, 6882378 bytes compressed: 90.3%</pre>
<p>If there's no PostgreSQL instance running on the Staging/Target host, however, we have a PostgreSQL installation, even then the plugin relies on the "DELPHIX_PG_PATH" variable to discover the environment.</p> <p>In the absence of "DELPHIX_PG_PATH" variable or if the value of "DELPHIX_PG_PATH" variable is NULL then Linux "find" command will be used for the Environment discovery which may impact the overall performance. Hence, it is preferred to create this Environment Variable with correct entries.</p> <p>In order to optimize the performance, it is preferred to create an Environment Variable "DELPHIX_PG_PATH" which should be accessible by OS users.</p>	<p>Below should be the syntax for "DELPHIX_PG_PATH" variable:</p> <pre>DELPHIX_PG_PATH= "binary_path:data_path1;binary_path:dat a_path2;"</pre> <p>For example:</p> <pre>DELPHIX_PG_PATH="/usr/pgsql-9.6/bin:/ var/lib/pgsql/9.6/data;/opt/edb/as9.6/ bin:/ opt/edb/as9.6/data;/usr/pgsql-9.6/bin:/ tmp/TESTING/data;"</pre>

 The variable "DELPHIX\_PG\_PATH" must be available to the environment user in a non-interactive way. You can test this variable for non-interactive logins using `ssh <your_username>@<target_host> "env | grep DELPHIX_PG_PATH"`.

## Network and connectivity requirements for PostgreSQL environments

### Overview

This topic covers the general network and connectivity requirements for the Delphix Engine, including connection requirements, port allocation, and firewall and Intrusion Detection System (IDS) considerations. For platform-specific network and connectivity requirements, see the relevant topics under the Requirements section for each platform.

### General outbound from the Delphix engine port allocation

Protocol	Port Numbers	Use
TCP	25	Connection to a local SMTP server for sending email
TCP/UDP	53	Connections to local DNS servers
UDP	123	Connection to an NTP server
UDP	162	Sending SNMP TRAP messages to an SNMP Manager
TCP	443	HTTPS connections from the Delphix Engine to the Delphix Support upload server
TCP/UDP	636	Secure connections to an LDAP server
TCP	8415	Connections to a Delphix replication target. See <a href="#">Configuring Replication</a>
TCP	50001	Connections to source and target environments for network performance tests.

### General inbound to the Delphix Engine port allocation

Protocol	Port Numbers	Use
TCP	22	SSH connections to the Delphix Engine
TCP	80	HTTP connections to the Delphix GUI
UDP	161	Messages from an SNMP Manager to the Delphix Engine
TCP	443	HTTPS connections to the Delphix Management Application

Protocol	Port Numbers	Use
TCP	8415	Delphix Session Protocol connections from all DSP-based network services including Replication, SnapSync for Oracle, V2P, and the Delphix Connector.
TCP	50001	Connections from source and target environments for network performance tests via the Delphix CLI. See <a href="#">Network Performance Tool</a>

### Firewalls and Intrusion Detection Systems (IDS)

Production databases on source environments (for dSources) are often separated from the non-production environment by firewalls. Firewalls can add milliseconds to the latency between servers. Accordingly, for best performance, there should be no firewalls between the Delphix Engine and the virtual database (VDB) target environments. If the Delphix Engine is separated from a source environment by a firewall, the firewall must be configured to permit network connections between the Delphix Engine and the source environments for the application protocols (ports) listed above.

Intrusion detection systems (IDSs) should also be made permissive to the Delphix Engine deployment. IDSs should be made aware of the anticipated high volumes of data transfer between dSources and the Delphix Engine.

### SSHD Configuration

Target Unix environments are required to have `sshd` running and configured such that the Delphix Engine can connect over `ssh`.

The Delphix platform expects to maintain long-running, highly performant `ssh` connections with remote Unix environments.

### Network and connectivity requirements for PostgreSQL

- IP connections must exist between the Delphix Engine and the target environments.
- The Delphix Engine uses an **SSH** connection to each target environment, **NFS** connections from each target environment to the Delphix Engine, and **PostgreSQL client** connections to the virtual databases on the target environment.
- Once connected to a staging target environment through **SSH**, the Delphix Engine initiates a **PostgreSQL replication client** connection from the target environment to the source environment.

### Port allocation for PostgreSQL environments

The following diagram describes the port allocations for PostgreSQL environments. It illustrates the ports that we recommend to be open from Delphix to remote services, to the Delphix Engine, and to the Target Environments.

Port allocation for PostgreSQL environments

**Note:** PostgreSQL listener typically runs on TCP 5432. In cases where other ports are used, substitute for 5432 above.

Outbound from the Delphix Engine port allocation

Protocol	Port Numbers	Use
TCP	22	SSH connections to the target database environment
TCP	xxx	PostgreSQL client connections to the PostgreSQL instances on the target environments (port 5432 by default)

Inbound to the Delphix Engine port allocation

Protocol	Port Number	Use
TCP/UDP	111	Remote Procedure Call (RPC) port mapper used for NFSv3 mounts
TCP	1110	Network Status Monitor (NSM) client from target hosts to the Delphix Engine
TCP	2049	NFS client from target hosts to the Delphix Engine (NFSv3 and NFSv4)

Protocol	Port Number	Use
TCP	54043	Client mount daemon (NFSv3 only)
TCP	54044	Lock state notification service (NFSv3 only)
TCP	54045	Network Lock Manager (NLM) client from target hosts to Delphix Engine (NFSv3 only)
UDP	33434 - 33464	Traceroute from the target database server to the Delphix Engine (optional)

#### Port allocation between source and staging target environments

Outgoing	Incoming	Protocol	Port Number	Use
Target Environment	Source Environment	PostgreSQL replication client	xxx	PostgreSQL replication client connection to the PostgreSQL instances on the source environment (port 5432 by default)

## Sudo privilege requirements for PostgreSQL environments

This topic describes the rationale behind specific sudo privilege requirements for virtualizing PostgreSQL Databases.

The sudo configuration exists as /etc/sudoers file.

Below is the example of sudo configuration file contents as mentioned above for Postgres environment.

```
$ vi /etc/sudoers
```

```
Defaults:postgres !requiretty
```

```
postgres ALL=NOPASSWD: /bin/mount,/bin/umount,/bin/mkdir,/bin/rmdir
```

Privilege	Sources	Targets	Rationale
mkdir/rmdir	Not Required	Required	Delphix dynamically creates and removes directories under the provisioning directory during VDB operations.
mount/ umount	Not Required	Required	Delphix dynamically mounts and unmounts directories under the provisioning directory during VDB operations. This privilege is required because mount and unmount are typically reserved for superuser.

 It is required to specify the NOPASSWD qualifier within the "sudo" configuration file, as shown here: [Sudo File Configuration Examples for PostgreSQL Environments](#). This ensures that the "sudo" command does not demand the entry of a password, even for the "display permissions" (i.e. "sudo -l") command.

### AppData mount options

Depending on the NFS version used options vers=3 or vers=4.x is added (x varies depending on what that platform supports. e.g. vers=4 or vers=4.1)

Linux (NFSv3)	<pre>-t nfs -o rw,fg,hard,rsize=1048576,wsiz=1048576,nointr,timeo=600,tcp,noacl,vers=3</pre> <p>Copy</p>
---------------	----------------------------------------------------------------------------------------------------------

Linux (NFSv4)	<pre data-bbox="427 309 1422 427">-t nfs4 -o rw,fg,hard,rsize=1048576,wsiz=1048576,nointr,timeo=600,sec=sys,tcp,noacl</pre> <p data-bbox="427 436 483 465">Copy</p>
<p data-bbox="169 517 236 546">Note :</p> <p data-bbox="169 562 999 591">(For some flavors of Linux and NFSv4.1, additional optional 'v4.1' is added)</p> <ol data-bbox="177 611 719 640" style="list-style-type: none"><li data-bbox="177 611 719 640">1. "port=2049" option is added for all platforms.</li></ol>	
<b>unmount options</b>	"-f" is used for all platforms. For Linux, "-lf" is used.

**Mount and unmount options subject to change**

Please note that the mount and unmount options listed above are subject to change. For example, if Delphix finds that a certain option improves performance, Delphix may add, remove or change options at anytime. Therefore, it is highly recommended to create the sudo profiles using wildcards that allow any number of options.

## Sudo file configuration examples for PostgreSQL environments

This topic describes the rationale behind specific sudo privilege requirements for virtualizing PostgreSQL Databases.

The sudo configuration exists as `/etc/sudoers` file.

### Requiretty settings

Delphix requires that the `requiretty` setting be disabled for all Delphix users with `sudo` privileges.

Configuring `sudo` access on Linux for PostgreSQL target environments

Below is the example of sudo configuration file contents as mentioned above for the Postgres environment.

```
$ vi /etc/sudoers
Defaults:postgres !requiretty
postgres ALL=NOPASSWD: /bin/mount,/bin/umount,/bin/mkdir,/bin/rmdir
```

Note that the following examples are for illustrative purposes and the sudo file configuration options are subject to change.

### Example 1

This example restricts the PostgreSQL user's use of `sudo` privileges to the directory `/postgres`.

Note that wildcards are allowed for the options on `mount` and `umount` because those commands expect a fixed number of arguments after the options. The option wildcard on the `mount` command also makes it possible to specify the file-system being mounted from the Delphix Engine.

However, wildcards are not acceptable on `mkdir` and `rmdir` because they can have any number of arguments after the options. For those commands, you must specify the exact options (`-p`, `-p -m 755`) used by the Delphix Engine.

Example: `/etc/sudoers` File Configuration on the Target Environment for sudo Privileges on the VDB Mount Directory Only (Linux OS)

```
Defaults:postgres !requiretty
delphix_os ALL=(root) NOPASSWD: \
/bin/mount * /postgres/*, \
/bin/umount * /postgres/*, \
/bin/umount /postgres/*, \
/bin/mkdir -p /postgres/*, \
/bin/mkdir -p -m 755 /postgres/*, \
/bin/mkdir /postgres/*, \
/bin/rmdir /postgres/*
```

## Example 2

This example restricts the PostgreSQL user's use of `sudo` privileges to the directory `/postgres`, restricts the mount commands to a specific Delphix Engine hostname and IP, and does not allow user-specified options for the `umount` command.

This configuration is more secure, but there is a tradeoff with deployment simplicity. This approach would require a different sudo configuration for targets configured for different Delphix Engines.

Example: Configuring the `/etc/sudoers` File on the Target Environment for Privileges on the VDB Mount Directory Only (Linux OS)

```
Defaults:delphix_os !requiretty
delphix_os ALL=(root) NOPASSWD: \
/bin/mount <delphix-server-name>* /postgres/*, \
/bin/mount * <delphix-server-name>* /postgres/*, \
/bin/mount <delphix-server-ip>* /postgres/*, \
/bin/mount * <delphix-server-ip>* /postgres/*, \
/bin/mount "", \
/bin/umount /postgres/*, \
/bin/umount * /postgres/*, \
/bin/mkdir [*] /postgres/*, \
/bin/mkdir /postgres/*, \
/bin/mkdir -p /postgres/*, \
/bin/mkdir -p -m 755 /postgres/*, \
/bin/rmdir /postgres/*
```

## Prerequisites for privilege elevation using DLPX\_DB\_EXEC script

### Updating DLPX\_DB\_EXEC script using Delphix Engine web APIs

In order to elevate privileges from a non-privileged OS account (like `delphix_os`) to a privileged OS account (like `postgres`), you must push a privilege elevation script (`dlpx_db_exec`) up into the Delphix Engine to become part of the Delphix common plugin.

### DLPX\_DB\_EXEC script

The privilege elevation profile script `dlpx_db_exec` allows you to execute commands that require superuser privileges on the source and target machines. The privilege elevation script `dlpx_db_exec` can be created or pushed to Delphix Engine using Web API calls, CURL or `dxtoolkit`. For steps on creating a Privilege Elevation Profile, see [CLI Cookbook: How to create or edit a privilege elevation profiles and profile scripts](#)

### Content of DLPX\_DB\_EXEC privilege elevation profile

```
#!/bin/sh
#
# Copyright (c) 2018 by Delphix. All rights reserved.
#
#
# This script allows customization of command execution with an alternate user
# account.
if [[ $1 != -u* ]]; then
    echo "Incorrect command line parameters, -u<optional user account> is required as
the first parameter"
    exit 1
fi
user_id=`echo $1 | sed -e "s/^-u//"`

shift 1
if [[ $user_id != "delphix_os" ]]; then
    command=$(printf "%s" "$@" )
    cd /tmp
    sudo -E su $user_id -p -c "$command"
else
    $@
fi
```

Below is an example of how you can push privilege elevation script “`dlpx_db_exec`” onto Delphix Engine.

1. Create a session to Delphix Engine as Delphix OS User.

```
curl -i -c cookies.txt -X POST -H "Content-Type:application/json" http://
<Delphix-Engine>/resources/json/delphix/session -d '{
  "version":{
    "minor":11,
    "major":1,
    "micro": 5,
```

```

    "type": "APIVersion"
  },
  "type": "APISession"
}'

```

The API Version needs to be identified as per the Delphix Engine installed at the customer site.

2. Login to the Delphix Engine as Delphix OS User.

```

curl -i -c cookies.txt -b cookies.txt -X POST -H "Content-Type:application/
json" http://<DELPHIX_ENGINE>/resources/json/delphix/login -d '{
  "password": "<PASSWORD>",
  "type": "LoginRequest",
  "target": "DOMAIN",
  "username": "<USERNAME>"
}'

```

3. Push DLPX\_DB\_EXEC contents to Delphix Engine.

```

curl -i -b cookies.txt -X POST -H "Content-Type:application/json" http://
<DELPHIX_ENGINE>/resources/json/delphix/host/privilegeElevation/profileScript/
HOST_PRIVILEGE_ELEVATION_PROFILE_SCRIPT-7 -d '{
  "type": "HostPrivilegeElevationProfileScript",
  "contents": "#\n# Copyright (c) 2018 by Delphix. All rights reserved.
\n#\n#\n# This script allows customization of command execution with an
alternate user\n# account.\n# if [[ $1 != -u* ]]; then\n#   echo \"Incorrect
command line parameters, -u<optional user account> is required as the first
parameter\"\n#   exit 1\n# fi\n# user_id=`echo $1 | sed -e \"s/^\n# -u\\/\n# \"\n# shift
1\n# if [[ $user_id != \"delphix_os\" ]]; then\n#   command=$(printf \"%s\n#
\n# \"$@)\n#   cd /tmp\n#   sudo -E su $user_id -p -c \"$command\"\n# else\n#
\n# fi\n#
}'

```

 Make sure that you edit the <USERNAME>, <PASSWORD> & <DELPHIX\_ENGINE> parameter values.

If the `d_lpx_db_exec` script is updated after the Environment(s) is added/created, then you must perform the **Refresh** operation to propagate the changes.

#### Staging/Target host requirements

To accomplish necessary tasks and run all Plugin operations hosts, the Delphix OS user account (henceforth referred to as "delphix\_os") requires privilege elevation specifications. Here is an example specification for the "sudo" privilege elevation utility, using the "visudo" to edit the "sudoers" configuration file. This specification makes the following assumptions:

- OS = Linux
- The Privileged OS account is named postgres.

 The following sudoers entry is only for template purposes. Modify the path in the below sudoers entry with the appropriate binary paths of your environment.

**Entry required for both Linking and Provisioning via low-privileged user (delphix\_os):**

#### Prerequisite for discovery operation

 The Discovery operation cannot be run by the high-privileged user, it will be executed by the low-privileged user.

1. The environment variable `DELPHIX_PG_PATH` should be accessible to the low privilege user. The variable `DELPHIX_PG_PATH` must be available to the environment (low-privileged) user in a non-interactive way. You can test this variable for non-interactive logins using `ssh <low_privileged_user>@<target_host> "env | grep DELPHIX_PG_PATH"`.
2. The paths mentioned inside the ``DELPHIX_PG_PATH`` should have read and execute permissions for a low-privileged user. Ex: `DELPHIX_PG_PATH="/usr/pgsql-9.6/bin:/var/lib/pgsql/9.6/data;"`

3. For the low-privileged user, if the `DELPHIX_PG_PATH` environment variable is not present, then the plugin traverses through the `/var` & `/opt` directories. And, if the installations are present in these parent folders, then you should have read and execute permissions for the whole set of directories that has the installation.
4. The `<postgres bin>` path [each directory in the path] should have read and execute permissions for the low privilege user.
5. The low-privilege user should be able to execute the `<postgres bin>/postgres --version` command. So, the plugin needs read and execute permissions for [just] `<postgres bin>/postgres` script. Other binaries/scripts will be run using the high-privileged user.

## Managing PostgreSQL environments and hosts

This topic section the attributes of Postgres environments such as information for the Delphix Connector and covers the following topics:

- [Setting up PostgreSQL environments: An overview](#)
- [Environment attributes for hosts with PostgreSQL](#)
- [Adding a PostgreSQL environment](#)
- [Adding an installation to a PostgreSQL environment](#)
- [Changing the hostname or IP address for PostgreSQL source and target environments](#)

### Setting up PostgreSQL environments: An overview

There are broadly three ways in which PostgreSQL source database can be made in sync with the staging Database:

1. Delphix Initiated Backup Ingestion + PostgreSQL Streaming Replication between Source and Staging Database.
2. Customer Initiated Backup Ingestion + PostgreSQL Streaming Replication between Source and Staging Database.
3. Customer Initiated Backup Ingestion + Source Database WAL logs application on Staging Server.

Each of the above approaches are described below:

Delphix for PostgreSQL architecture with Delphix initiated backup ingestion + PostgreSQL streaming replication between source and dSource

Below is the brief architecture of Delphix Engine support for PostgreSQL database with Delphix Initiated Backup + PostgreSQL Streaming Replication between Source and Staging Database.

Block Diagram of Linking Architecture Between PostgreSQL Environments and the Delphix Initiated Backup Platform.

Delphix for PostgreSQL architecture with customer initiated backup ingestion + PostgreSQL streaming replication between source and dSource

Below is the brief architecture of Delphix Engine support for the PostgreSQL database with External Backup + PostgreSQL Streaming Replication between Source and Staging Database.

Delphix for PostgreSQL architecture with customer initiated backup ingestion + WAL apply for resync between source and dSource

Below is the brief architecture of Delphix Engine support for the PostgreSQL database with External Backup + WAL application between Source and Staging Database.

### Types of PostgreSQL environments

At a high level, the Delphix Engine maintains a logical representation of the source database files, from which one can provision virtual databases (VDBs). In order to link a data source and provision a VDB, the following types of environments are required:

A source environment is where the un-virtualized source database runs. The Delphix Engine uses the backup, restore, and replication features of the PostgreSQL DBMS to maintain its internal representation of the source database, to be used for provisioning VDBs. The Staging host must be able to connect to the source environment in order to orchestrate the backup, restore, and replication functionality necessary to keep its representation synchronized with the source database. The Delphix Engine is designed to have a minimal impact on the performance of the source database and the source environment.

A target environment is where virtualized databases run. PostgreSQL target environments serve two purposes:

1. Since PostgreSQL does not provide a native incremental backup API, a warm standby server (in other words, one in log-shipping mode) must be created where all database files are stored remotely on a Delphix Engine. We refer to the creation and maintenance of this staging database as validated sync. During validated sync, we retrieve data from the source, roll the staged database forward, ensure that all the components necessary for provisioning a VDB have been validated, and create a snapshot of that data state. The result of validated sync is both a TimeFlow with consistent points from which you can provision a VDB and a faster provisioning process because there is no need for any database recovery when provisioning a VDB. In order to create a staging database, you must designate a target environment for this task when linking a dSource. During the linking process, database files are exported over the network to the target environment, where

the staging database instance runs as a warm standby server. A target environment that hosts one or more staging databases is referred to as a staging target for validated sync.

2. Once a staging database has been set up, you can provision virtual databases from any of the discreet snapshots along the TimeFlow mentioned above to any compatible target environment (for more information, see [Requirements for PostgreSQL hosts and databases](#)). Database files are exported over the network to the target environment, where the virtual database instance runs.

#### Workflow for PostgreSQL environments

Prior to provisioning a virtual database, a compatible target environment must be added to the Delphix Engine. This may be the same target environment as that used for the staging instance, or it may be a different target environment.

Once an environment is added to the Delphix Engine, environment discovery takes place. Environment discovery is the process of enumerating PostgreSQL installations and configurations when a source or target environment is added to the Delphix Engine. The discovery process is repeated during environment refresh in order to detect new PostgreSQL installations and clusters.

## Environment attributes for hosts with PostgreSQL

This topic describes the attributes of PostgreSQL environments. Below you will see a section for common environment attributes shared by all types of environments as well as Postgres specific ones.

### Procedure

1. Login to the Delphix Management application.
2. Click **Manage**.
3. Select **Environments**.
4. In the Environments panel, click the name of an environment to view its attributes.
5. Next to **Attributes**, click the Pencil icon to edit an attribute.

### Common environment attributes

Attribute	Description
Environment Users	The users for that environment. These are the users who have permission to ssh into an environment or access the environment through the Delphix Connector. For more information on the environment user requirements, see the Requirements topics for specific data platforms.
Host Address	The IP address of the environment host.
DSP KeyStore Path	The path to the user-managed DSP Keystore.
DSP KeyStore Alias	The lowercase alias to use inside the user-managed DSP Keystore.
DSP KeyStore Password	The password for the user-managed DSP Keystore.
DSP TrustStore Path	The path to the user managed DSP truststore.
DSP TrustStore Password	The password for the user managed DSP truststore.
OS	The name of the host operating system.
Version	The version of the host operating system.
Release	The release of the host operating system.
Time Zone	The timezone of the host operating system.
Total RAM	The amount of RAM on the host machine.

Attribute	Description
Processor Type	The processor type of the host machine.
Traceroute	Traceroute info from target host to Delphix Engine.
Notes	Any other information you want to add about the environment.
Java Development Kit	The currently selected JDK kit will be shown.
Java Development Kit (JDK) Path	Location of the Java Development Kit (JDK) used for the host. Only specified if the feature to provide your own JDK is enabled, otherwise, the defaults are used per our <a href="#">Java support matrix</a> .

#### PostgreSQL environment attributes

There are no postgres-specific environment attributes.

## Adding a PostgreSQL environment

This topic describes how to add a PostgreSQL Staging environment.

### Prerequisites

- Make sure that the staging environment in question meets the requirements described in [Requirements for PostgreSQL hosts and databases](#) and Prerequisites for Discovery operation described in the [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#) section.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next, to Environments, click the Actions (...) menu and select **Add Environment**.
5. In the Add Environment dialog, select **Unix/Linux**.
6. Select **Standalone Host**.
7. Click **Next**.
8. Enter Name for the Environment.
9. Enter the **Host IP address** or **hostname**.
10. Enter the **SSH port**. The default value is 22.
11. Enter an **OS Username** for the Environment. If a low-privileged OS user is used, make sure the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) are met.
12. Select **Login Type**. — Username and Password - enter the OS username and password — Username and Public Key - enter the OS username. — Password Vault - select from an existing Enterprise Password Vault

#### **Note:**

[Using Public Key Authentication](#)

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

- a. Select **Public Key** for the **Login Type**.
- b. Click **View Public Key**.
- c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See Option 2 in [this CLI Cookbook article](#) for instructions.

13. For Password, enter the password associated with the user in step 11.
14. If you want to use Public Key Encryption for logging into your environment:
  - a. Select Public Key for the Login Type.
  - b. Click View Public Key.
  - c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
    - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).

- ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
- iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail. The public key needs to be added only once per user and per environment. You can also add public key authentication to an environment user's profile by using the command-line interface, as explained in the topic [CLI Cookbook: Setting up SSH key authentication for UNIX environment users](#)
15. For Password Login, click Verify Credentials to test the username and password.
16. Enter **Toolkit Path** (make sure Toolkit path does not have spaces).
17. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
18. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
19. Click **Submit**.

As the new environment is added, you will see two jobs running in the Delphix platform Job History, one to Create and Discover an environment, and another to create an environment. When the jobs are complete, you will see the new environment added to the list in the Environments tab. If you do not see it, click the Refresh icon in your browser.

Once the environment is discovered, further linking would require adding a source config to the above-discovered installation. Please refer to [Linking a PostgreSQL dSource](#) for more information.

## Post requirements

To view information about an environment after you have created it:

1. Click **Manage**.
2. Select **Environments**.
3. Select the environment name.

## Adding an installation to a PostgreSQL environment

If a new PostgreSQL Installation is added to the environment, then in order to reflect it into the Delphix Engine, it is required to refresh the environment. Please refer to the "Environment Refresh" section at [Managing environments and hosts](#) for more details.

This topic describes how to refresh a PostgreSQL environment to reflect the changes if any.

## Changing the hostname or IP address for PostgreSQL source and target environments

Below is the procedure to change the Host Address of the PostgreSQL Source and Target Environments (If the Host address of the underlying Source and Target server has also changed):

### Procedure

1. Disable the dSources.
2. Disable the VDBs.
3. Login to the **Delphix Management** application.
4. Click **Manage**.
5. Select **Environments**.
6. Click on the existing environment name you want to modify and open the environment information screen.
7. In the **Attributes** section, click the **Pencil** icon located next to it.
8. Update the **Host address** to the new one and save the results by clicking on the **Save (Tick)** icon. The new Host address will now be updated.
9. Re-enable the dSources.
10. Re-enable the VDBs.

## Linking data sources and syncing data with PostgreSQL

Creating a dSource will ingest data from the source and create a dSource on the engine. The dSource is an object that the Continuous Data Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools.

This section covers the following topics:

- [Linking PostgreSQL data sources: Overview](#)
- [Data management settings for PostgreSQL data sources](#)
- [Linking a PostgreSQL dSource](#)
- [Staging push implementation](#)
- [Working with PostgreSQL snapshots](#)
- [Source sizing implementation for dSource](#)

## Linking PostgreSQL data sources: Overview

This topic describes basic concepts behind the creation of a dSource from PostgreSQL instance.

For an overview of all dSource related actions, please visit [Managing data sources and syncing data](#) in the Getting Started section of the Datasets documentation.

When linking a dSource from a PostgreSQL source database, Delphix offers different methods of capturing backup information:

1. dSource created with External Backup and syncing data with WAL files.
2. dSource created with External Backup and syncing data with PostgreSQL Streaming Replication.
3. dSource created with Delphix Initiated Backup, leveraging PostgreSQL Streaming Replication to sync data from the source database.
4. dSource created with Delphix Initiated Backup, leveraging Single database ingestion to sync data from the source database.
5. dSource created with the Staging Push method.

 If you are using an external backup and have checked both options above, then PostgreSQL Streaming Replication will take precedence over syncing with WAL files.

 For Delphix initiated and external backups, the streaming replication is monitored by reading the PostgreSQL database logs every minute. If the streaming replication stops due to any reason, a fault is generated and an error message is displayed under the **Status tab**.  
The snapshot operation will also fail if the streaming replication stops with a fault.

After obtaining the initial snapshot and linking the dSource, the Delphix Engine keeps the staging and the source database in sync by monitoring the source database for new transaction logs on the staging target and then applying those transaction logs on the staging database. PostgreSQL streaming replication protocol is used to achieve data replication between the source database and the staging database.

 We can also use the source host as a staging host because the PostgreSQL database runs on different ports.

## Data management settings for PostgreSQL data sources

This topic describes advanced data management settings for dSources.

When linking a dSource, you can use custom data management settings to improve overall performance and match the needs of your specific server and data environment. If no specific settings are required, leverage default data management settings.

### Accessing data management settings

There are three ways to set or modify data management settings for dSources:

1. During the dSource linking process, in the Policies tab of the Add dSource wizard, select the **Retention Policy**.
2. Or select **Manage**, then select **Policies**. To manage retention on target after the dSource snapshots have been deleted from the replication source, select the **Replica Retention** tab.
3. In the Policies screen, select the **Retention** tab.
4. To add a new retention policy click the **+Retention** button, and to add a new replica retention policy on the replication target, click the **+Replica Retention** button.
5. This will open the Retention Policy wizard. Enter a policy name, select your retention periods and click Submit. For more information, see [Policies for scheduled jobs](#)

### Retention policies - retention/replica retention

Retention policies define the length of time Delphix Engine retains snapshots within its storage. To support longer retention times, you may need to allocate more storage to the Delphix Engine. The retention policy – in combination with the SnapSync policy – can significantly impact the performance and storage consumption of the Delphix Engine.

Replica Retention policies define how long the snapshots are retained on replicated namespaces for dSources and VDBs after they have been deleted on the replication source. Normally, the snapshots that have been deleted on the replication source engine are also deleted on the replication target engine. A new retention policy is introduced to provide an extended lifetime of such snapshots on the replication target.

### Benefits of longer retention

With increased retention time for snapshots and logs, you allow a longer (older) rollback period for your data.

Common use cases for longer retention include:

- SOX compliance
- Frequent application changes and development
- Caution and controlled progression of data
- Reduction of project risk
- Restore to older snapshots

## Linking a PostgreSQL dSource

Overview of the linking process

The **PostgreSQL plugin version 2.0.0** and above provides the following ways to create a dSource:

- dSource created with Delphix Initiated Backup - there are two ways to do this:
  - Cluster level backup via `pg_basebackup` and keep in sync through [PostgreSQL Streaming Replication](#)
  - [Single database backup](#) via `pg_dump` and `pg_restore`
- dSource created with External Backup - there are two ways to do this:
  - keep in sync with the source through [WAL files](#)
  - keep in sync with the source through [PostgreSQL Streaming Replication](#)

**[-]** If both options are used - **keep in sync with the source through WAL files** and **keep in sync with the source through PostgreSQL Streaming Replication**, then **PostgreSQL Streaming Replication** will take precedence, and syncing through WAL files will not be considered.

With **PostgreSQL plugin version 2.1.0** and above, the end -user can use the Privilege Elevation feature:

- Initially, the discovery operation will be executed by the Environment OS user that was provided while adding the environment.
- If you are using the two environment users, make sure both the user can access [read+write+execute] the toolkit path & the scratch path: `<toolkit_path>/Delphix_COMMON_<id>/plugin/postgres-vsdk_<id>/`.

**Basic Information**

ENVIRONMENT USERS + ✎ ★ 🗑

Primary	Name
★	postgres
	delphix_os

- Either create all the directories/files required by the dSource ingestion mechanisms using the high-privileged user or they should be accessible to the high-privileged user.
  - **External Backup Mechanism:**
    - PostgreSQL Backup File Path (Directory), with a minimum of read and execute permissions for the high-privileged user.
    - The provided backups (either the zip or full-backup tarballs) should be readable by the high-privileged user.
    - PostgreSQL Backup WAL Log Files Path (Directory), with read, write and execute permissions for the high-privileged user.
    - The WAL logs within the WAL Log Files Path should be readable by the high-privileged user.
  - **Single DB Backup:**
    - Postgres Backup Dump Directory, with a minimum of write and execute permissions for the high-privileged user.
    - The `Staging postgresql.conf` config file should be readable by the high-privileged user.

**With PostgreSQL plugin version 3.2.0**, an enhancement has been made to the External Backup mechanism. Previously the only way to provide source backup was via a compressed ZIP file(s) (in the format `PostgreSQL_T<YYYYMMDD>.zip`). Now we can provide backups in the following ways:

- Method 1: **Using structured folders** [highest precedence]
  - Place the `pg_basebackup` tar output inside the folder(s) named `PostgreSQL_T<YYYYMMDDhhmmss>`; created within the backup path.

```
# As an example
$ ls -l <backup_path>/PostgreSQL_T20230224033939
-rw-----. 1 postgres postgres 9093632 Feb 24 03:39 24578.tar
-rw-----. 1 postgres postgres 9093632 Feb 24 03:39 24579.tar
-rw-----. 1 postgres postgres 9093632 Feb 24 03:39 24580.tar
-rw-----. 1 postgres postgres 294300 Feb 24 03:39 backup_manifest
-rw-----. 1 postgres postgres 26959360 Feb 24 03:39 base.tar
-rw-----. 1 postgres postgres 16778752 Feb 24 03:39 pg_wal.tar
```

- Method 2: **Using the backup path directly** [preference given over ZIP files placed within the same backup path]
  - Place the `pg_basebackup` tar output inside the backup path directly

```
# As an example
$ ls -l <backup_path>
-rw-----. 1 postgres postgres 9093632 Feb 24 02:12 24578.tar
-rw-----. 1 postgres postgres 9093632 Feb 24 02:12 24579.tar
-rw-----. 1 postgres postgres 9093632 Feb 24 02:12 24580.tar
-rw-----. 1 postgres postgres 26959360 Feb 24 02:12 base.tar
-rw-----. 1 postgres postgres 16778752 Feb 24 02:12 pg_wal.tar
-rw-r--r--. 1 postgres postgres 6883130 Feb 24 02:28
PostgreSQL_T20230224.zip
```

- Method 3: **Using the ZIP files** [existing method]
  - Place the ZIP file which contains the `pg_basebackup` output inside the backup path. Make sure that the backup files are available directly at the root level of the ZIP.

```
# As an example
# The backup files are available at the root of the ZIP file
$ zipinfo PostgreSQL_T20230224.zip
Archive: PostgreSQL_T20230224.zip
Zip file size: 6883130 bytes, number of entries: 5
-rw----- 3.0 unx 9093632 bx defN 23-Feb-24 02:12 24578.tar
-rw----- 3.0 unx 9093632 bx defN 23-Feb-24 02:12 24579.tar
-rw----- 3.0 unx 9093632 bx defN 23-Feb-24 02:12 24580.tar
-rw----- 3.0 unx 26959360 bx defN 23-Feb-24 02:12 base.tar
-rw----- 3.0 unx 16778752 bx defN 23-Feb-24 02:12 pg_wal.tar
5 files, 71019008 bytes uncompressed, 6882378 bytes compressed: 90.3%
```

The following sections provide step by steps instructions on how to do this.

## Creating a dSource with external backups using WAL Logs

The following procedure provides details on creating a dSource with External Backup which uses WAL logs to keep in sync with the source.

### Prerequisites

- The source and staging instances must meet the host requirements.
- Databases must meet container requirements.
- If Privilege Elevation is to be used:
  - The `PostgreSQL Backup File Path` should have read+execute permissions for the high-privileged user.
  - The backup file(s) should have read permission for the high-privileged user.
  - The `PostgreSQL Backup WAL Log Files Path` should have read+write+execute permissions for the high-privilege user.
  - The WAL logs within `WAL Log Files Path` should have read permission for the high-privilege user.
- Else, `PostgreSQL Backup File Path` & `PostgreSQL Backup WAL Log Files Path` must be available and accessible by the Environment OS user.
- **From plugin versions greater than 3.2.0**, the `pg_basebackup` database full backup can be provided in three ways, in the order of high-to-low precedence:
  - a. The backup files are placed within the organized folder(s) inside the `PostgreSQL Backup File Path` named `PostgreSQL_T<YYYYMMDDhhmmss>` ; Backups from the folder with the latest timestamp in the name will be chosen when dSource creation/resync takes place.
    - i. Creation of folder(s) on the staging server:

```
DLXPGBACKUPDIR=PostgreSQL_T$(date "+%Y%m%d%H%M%S")
mkdir -p <backup_path>/$DLXPGBACKUPDIR
```

- ii. Taking the source backup on the staging server using `pg_basebackup`:

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <backup_path>/$DLXPGBACKUPDIR -F t
-v -w -P -x -h <source_ip_domain_name> -p <source_port> -U
<source_user>

# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <backup_path>/$DLXPGBACKUPDIR -F t
-v -w -P -Xs -h <source_ip_domain_name> -p <source_port> -U
<source_user>
```

- b. The backup files are placed directly within the `PostgreSQL Backup File Path` .
  - i. Make sure to redirect the `pg_basebackup` output to an empty directory and then move it to `<backup_path>` .

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <path_to_empty_directory> -F t -v -w
-P -x -h <source_ip_domain_name> -p <source_port> -U <source_user>
```

```
# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <path_to_empty_directory> -F t -v -w
-P -Xs -h <source_ip_domain_name> -p <source_port> -U <source_user>

# Move files
mv <path_to_empty_directory>/* <backup_path>
```

- c. The backup files are encapsulated in a ZIP file named `PostgreSQL_T<YYYYMMDD>.zip` and placed within `PostgreSQL Backup File Path`.

- i. Taking the source backup on the source server using `pg_basebackup`:

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <destination_path> -F t -v -w -P -x

# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <destination_path> -F t -v -w -P -Xs
```

- ii. Creating a ZIP file that can be moved to the staging server (please make sure the backup files are at the root of the ZIP file):

```
cd <destination_path>
# The back files should be at the root of the ZIP file
DLPXPGBACKUPZIP=PostgreSQL_T$(date +"%Y%m%d").zip
zip $DLPXPGBACKUPZIP *
```

For more information refer to [Requirements for PostgreSQL source hosts and databases](#) and [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC Script](#) section.

#### Limitation

It is not possible to access the staging server with PostgreSQL 9.4 and PostgreSQL 9.5 versions.

#### Procedure

1. Log in to the **Delphix Management** application.
2. Select **Manage > Environments**.
3. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.
4. In the **Add Database** dialog window enter the **Name** for your source config and click **Add**.
5. Select your source config and click the **Add dSource** link located to the right.
6. In the **Source** tab, do the following:
  - a. In the **NFS Mount Location** field, enter a mount location on the staging host.
  - b. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) section.

#### Note:

You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.

If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

- access to the Postgres commands
  - read+write+execute permissions on the `unix\_socket\_directories` configured in `postgresql.conf` [Default directories: `/var/run/postgresql` & `/tmp`]
- c. Click on the **+Add** icon located next to **External Backup** Parameter.

**Note:**

The Add Button provided for External Backup is clickable multiple times but should be used **ONLY** once since the solution is built only to support a single backup path. Providing Multiple Paths will error out the linking process.

- d. **PostgreSQL Backup File Path** - the location of the backup file
- e. **PostgreSQL Backup WAL Log Files Path** - the location of the WAL log files

**Data Type**

AppData

NFS Mount Location \*

/tmp/dSource

Mount Location on Staging Host [No spaces allowed]

Privileged OS Account (Optional)

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation. Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

## External Backup

dSource Creation through external backup

PostgreSQL Backup File Path \*

/tmp/backup

 Delete

Path to the database backup

PostgreSQL Backup WAL Log Files Path

/tmp/wal\_logs

Allow the dSource to restore the WAL log files from this path

Enable streaming replication if WalLogs are not provided

Allow the dSource to be in sync with Source through streaming replication if WalLogs are not provided. \*Streaming Replication Parameters\* are mandatory for this.

**+ Add**

**Note:**

Once the dSource is up using the Full External Backup provided on the staging environment, the dSource will continue to run in recovery mode and will wait for the next expected WAL file under the specified **PostgreSQL backup WAL log Files** path. When the expected WAL files are placed on this path, the dSource applies this WAL file and starts waiting for the next expected WAL files in series. If the WAL file provided is invalid or not in the sequence, then the dSource will throw an error on UI with the information of the expected WAL filename when the next dSource snapshot is taken. In the case of a WAL chain break, users need to either resynchronize the dSource or provide the missing WAL file, then disable and enable the dSource database

- f. **Staging Instance Port Number** - must be unique for a given instance.
- g. Optionally, database configuration parameters can be defined during the linking operation in the Config Settings section.

## Config Settings

### Custom Database-Level config settings

Property Name \*

ssl

Delete

Value

off

Comment Property

Select this option to comment out the provided property name in the configuration file

+ Add

h. Click **Next**.

7. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
8. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
9. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
10. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
11. In the **Summary** tab, review the configuration profile for the dSource.
12. Click **Submit**. The Delphix Engine initiates two jobs to create the dSource: DB\_Link and DB\_Sync. You can monitor these jobs by clicking **Active Jobs** from the top menu bar, or by selecting **System > Event Viewer**. When the jobs have successfully been completed, the database icon will change to a dSource icon on the **Environments > Host > Databases** screen, and the dSource will also appear in the list of Datasets under its assigned group.

#### The dSource Configuration Screen

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations

### Creating a dSource with external backups using streaming replication

The following procedure provides details on creating a dSource with External Backup which uses streaming replication to keep in sync with the source.

#### Prerequisites

- The source and staging instances must meet the host requirements
- Databases must meet container requirements.
- If Privilege Elevation is being used:

- The **PostgreSQL Backup File Path** should have read+execute permissions for the high-privileged user.
- The backup file `>>` should have read permission for the high-privileged user.
- Else, PostgreSQL Backup Files Path must be available and accessible by the Environment OS user.
- **For plugin versions greater than 3.2.0**, the `pg_basebackup` database full backup can be provided in three ways, in the order of high-to-low precedence:
  - a. The backup files are placed within the organized folder(s) inside the **PostgreSQL Backup File Path**, named `PostgreSQL_T<YYYYMMDDhhmmss>`. Backups from the folder with the latest timestamp in the name will be chosen when dSource creation/resync takes place.
    - i. Creation of the folder(s) on the staging server:

```
DLPXPGBACKUPDIR=PostgreSQL_T$(date "+%Y%m%d%H%M%S")
mkdir -p <backup_path>/$DLPXPGBACKUPDIR
```

- ii. Taking the source backup on the staging server using `pg_basebackup`:

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <backup_path>/$DLPXPGBACKUPDIR -F t
-v -w -P -x -h <source_ip_domain_name> -p <source_port> -U
<source_user>

# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <backup_path>/$DLPXPGBACKUPDIR -F t
-v -w -P -Xs -h <source_ip_domain_name> -p <source_port> -U
<source_user>
```

- b. The backup files are placed directly within the **PostgreSQL Backup File Path**.
  - i. Make sure to redirect the `pg_basebackup` output to an empty directory and then move it to `<backup_path>`.

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <path_to_empty_directory> -F t -v -w
-P -x -h <source_ip_domain_name> -p <source_port> -U <source_user>

# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <path_to_empty_directory> -F t -v -w
-P -Xs -h <source_ip_domain_name> -p <source_port> -U <source_user>

# Move files
mv <path_to_empty_directory>/* <backup_path>
```

- c. The backup files are encapsulated in a ZIP file named `PostgreSQL_T<YYYYMMDD>.zip` and placed within **PostgreSQL Backup File Path**.
  - i. Taking the source backup on the source server using `pg_basebackup`:

```
# For PostgreSQL versions 9.4.x,9.5.x,9.6.x
<path_to_bin>/pg_basebackup -D <destination_path> -F t -v -w -P -x
```

```
# For PostgreSQL versions 10.x and above
<path_to_bin>/pg_basebackup -D <destination_path> -F t -v -w -P -Xs
```

- ii. Creating a ZIP file that can be moved to the staging server (please make sure the backup files are at the root of the ZIP file):

```
cd <destination_path>

# The back files should be at the root of the ZIP file
DLPXPGBACKUPZIP=PostgreSQL_T$(date +"%Y%m%d").zip
zip $DLPXPGBACKUPZIP *
```

For more information refer to [Requirements for PostgreSQL hosts and databases](#) and [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#) section.

#### Limitation

It is not possible to access the staging server with PostgreSQL 9.4 and PostgreSQL 9.5 versions.

#### Procedure

1. Login to the **Delphix Management** application.
2. Select **Manage > Environments**.
3. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.
4. In the **Add Database** dialog window enter the **Name** for your source config and click **Add**.
5. Select your source config and click the **Add dSource** link located to the right.
6. In the **Source** tab, do the following:
  - a. In the **NFS Mount Location** field, enter a mount location on the staging host.
  - b. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisites for Privilege Elevation using DLPX\\_DB\\_EXEC Script](#) section.
 

**Note:**  
You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.  
If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

    - access to the Postgres commands
    - read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]
  - c. Click on the **+Add** icon located next to **External Backup** Parameter.
  - d. **PostgreSQL Backup File Path** - the location of the backup file
  - e. Select the checkbox '**Enable streaming replication if WalLogs are not provided**'

**Data Type**  
AppData

NFS Mount Location \*  
/tmp/dSource

Mount Location on Staging Host [No spaces allowed]

Privileged OS Account (Optional)

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation.  
Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

**External Backup**

dSource Creation through external backup

PostgreSQL Backup File Path \*  
/tmp/backup

 Delete

Path to the database backup

PostgreSQL Backup WAL Log Files Path

Allow the dSource to restore the WAL log files from this path

Enable streaming replication if WalLogs are not provided

Allow the dSource to be in sync with Source through streaming replication if WalLogs are not provided. \*Streaming Replication Parameters\* are mandatory for this.

+ Add

- f. Click on the **+Add** icon located next to the **Delphix Initiated Backup/External Backup - Streaming Replication Parameters** option.

**Note:**

The Add Button provided for Delphix Initiated Backup/External Backup - Streaming Replication is clickable multiple times but should be used **ONLY** once since the solution is built only to support a single backup path. Providing Multiple Paths will error out the linking process.

The following fields are mandatory for this process :

- i. **PostgresDB Replication User**
- ii. **PostgresDB Replication User Password**
- iii. **Source Host Address**
- iv. **Source Instance Port Number**

**Enable streaming replication if WalLogs are not provided**

Allow the dSource to be in sync with Source through streaming replication if WalLogs are not provided. \*Streaming Replication Parameters\* are mandatory for this.

+ Add

**Delphix Initiated Backup - Postgres Cluster Ingestion Flag**

Allow Delphix to initiate the physical backup on source database. \*Streaming Replication Parameters\* are mandatory for ingestion.

## Delphix Initiated Backup/External Backup - Streaming Replication Parameters

List of parameters for Delphix initiated backup and external backup with streaming replication

PostgresDB Replication User \*

delphix

Delete

Replication User for Postgres database

PostgresDB Replication User Password \*

\*\*\*\*\*

Replication password for Postgres database

Source Host Address \*

sourcepg.dlpxdc.co

Source Host Address

Source Instance Port Number \*

5432

Port number for Postgres source database

+ Add

- g. **Staging Instance Port Number** - must be unique for a given instance.
- h. Optionally, database configuration parameters can be defined during the linking operation in the **Config Settings** section.

## Config Settings

Custom Database-Level config settings

Property Name \*

ssl

Delete

Value

off

**Comment Property**

Select this option to comment out the provided property name in the configuration file

+ Add

**Note:**

After dSource creation, users can now configure the parameters and their values in the `postgresql.conf` file through the "Config Settings" section on the Delphix Engine UI. For example, to support **Replication Slots** through UI, users can now provide the "primary\_slot\_name" parameter and its value through the UI. This will update the already existing parameter value in the `postgresql.conf` file with the value provided by the user.

Similarly, if a user wants to disable a parameter then they can provide the parameter name and select the checkbox **Comment Property**. This will comment out the parameter in the `postgresql.conf` configuration file.

- i. Click **Next**.
7. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
8. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
9. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
10. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
11. In the **Summary** tab, review the configuration profile for the dSource.
12. Click **Submit**. The Delphix Engine initiates two jobs to create the dSource: DB\_Link and DB\_Sync. You can monitor these jobs by clicking **Active Jobs** from the top menu bar, or by selecting **System > Event Viewer**. When the jobs have successfully been completed, the database icon will change to a dSource icon on the **Environments > Host > Databases** screen, and the dSource will also appear in the list of Datasets under its assigned group.

### The dSource Configuration Screen

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations.

## Creating a dSource with Delphix initiated backup using streaming replication

### Prerequisites

- The source and staging instances must meet the host requirements
- Databases must meet container requirements. For more information refer to [Requirements for PostgreSQL source hosts and databases](#)

### Limitation

It is not possible to access the staging server with PostgreSQL 9.4 and PostgreSQL 9.5 versions.

### Procedure

1. Log in to the **Delphix Management** application.
2. Select **Manage > Environments**.
3. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.

4. In the **Add Database** dialog window enter the **Name** for your source config and click **Add**.
5. Select your source config and click the **Add dSource** link located to the right.
6. In the **Source tab**, do the following:
  - a. In the **NFS Mount Location** field, enter a mount location on the staging host.
  - b. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#) section.

**Note:**

You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.

If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

- access to the Postgres commands
  - read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]
- c. Select the checkbox next to the **Delphix Initiated Backup - Postgres Cluster Ingestion Flag** option. Selecting this checkbox allows Delphix to initiate the physical backup on the source database.

**Data Type**

AppData

NFS Mount Location \*

/tmp/dSource

Mount Location on Staging Host [No spaces allowed]

Privileged OS Account (Optional)

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation.  
 Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

**External Backup**

dSource Creation through external backup

+ Add

Delphix Initiated Backup - Postgres Cluster Ingestion Flag

Allow Delphix to initiate the physical backup on source database. \*Streaming Replication Parameters\* are mandatory for ingestion.

- d. Click on the **+Add** icon located next to the **Delphix Initiated Backup/External Backup - Streaming Replication Parameters** option.

The following fields are mandatory for this process :

- i. **Delphix Initiated Backup - Postgres Cluster Ingestion Flag** - Checkbox should be selected.
- ii. **PostgresDB Replication User**
- iii. **PostgresDB Replication User Password**
- iv. **Source Host Address**
- v. **Source Instance Port Number**

Delphix Initiated Backup - Postgres Cluster Ingestion Flag

Allow Delphix to initiate the physical backup on source database. \*Streaming Replication Parameters\* are mandatory for ingestion.

### Delphix Initiated Backup/External Backup - Streaming Replication Parameters

List of parameters for Delphix initiated backup and external backup with streaming replication

PostgresDB Replication User *	delphix	 Delete
Replication User for Postgres database		
PostgresDB Replication User Password *	*****	
Replication password for Postgres database		
Source Host Address *	sourcepg.dlpxdc.co

 Add

- e. **Staging Instance Port Number** - must be unique for a given instance.
- f. Optionally, database configuration parameters can be defined during the linking operation in the **Config Settings** section.

### Config Settings

Custom Database-Level config settings

Property Name *	ssl	 Delete
Value	off	

Comment Property

Select this option to comment out the provided property name in the configuration file

 Add

**Note:**

After dSource creation, users can now configure the parameters and their values in the `postgresql.conf` file through the "Config Settings" section on the Delphix Engine UI. For example, to support **Replication Slots** through UI, users can now provide the "primary\_slot\_name" parameter and its value through the UI. This will update the already existing parameter value in the `postgresql.conf` file with the value provided by the user.

Similarly, if a user wants to disable a parameter then they can provide the parameter name and

select the check box **Comment Property**. This will comment out the parameter in the `postgresql.conf` configuration file.

- g. Click **Next**.
7. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
8. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
9. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
10. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
11. In the **Summary** tab, review the configuration profile for the dSource.
12. Click **Submit**. The Delphix Engine initiates two jobs to create the dSource: DB\_Link and DB\_Sync. You can monitor these jobs by clicking **Active Jobs** from the top menu bar, or by selecting **System > Event Viewer**. When the jobs have successfully been completed, the database icon will change to a dSource icon on the **Environments > Host > Databases** screen, and the dSource will also appear in the list of Datasets under its assigned group.

#### The dSource Configuration Screen

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations.

### Creating a dSource with Delphix initiated backup using single database ingestion

#### Prerequisites

- The source and staging instances must meet the host requirements
  - Databases must meet container requirements
  - If Privilege Elevation is being used:
    - The `Postgres Backup Dump Directory` should have write+execute permissions for the high-privileged user.
    - The `Staging postgresql.conf config file` should be accessible to the high-privileged user.
  - Else, `Postgres Backup Dump Directory & Staging postgresql.conf config file` must be available and accessible by the Environment OS user.
- For more information refer to [Requirements for PostgreSQL source hosts and databases](#) and [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#) section.

#### Procedure

Login to the **Delphix Management** application.

1. Select **Manage > Environments**.
2. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.
3. In the **Add Database** dialog window, enter the **Name** for your source config and click **Add**.

4. Scroll down to the source config that you added and click the **Add dSource** option located to the right.
5. In the **Source** tab, do the following:
  - a. In the **NFS Mount Location** field, enter a mount location on the staging host.
  - b. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisites for privilege elevation using DLPX\\_DB\\_EXEC script](#) section.

**Note:**

You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.

If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

- access to the the postgres commands
  - read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]
- c. Select the checkbox next to the **Delphix Initiated Backup - Single Database Ingestion** option. Selecting this checkbox allows Delphix to initiate the logical backup on the source database.

**Data Type**

AppData

NFS Mount Location \*

Mount Location on Staging Host [No spaces allowed]

Privileged OS Account (Optional)

This privileged unix username will be used to create the dSource. Leave this field blank if you do not want to use privilege elevation. Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

## External Backup

dSource Creation through external backup

**+ Add**

Delphix Initiated Backup - Postgres Cluster Ingestion Flag

Allow Delphix to initiate the physical backup on source database. \*Streaming Replication Parameters\* are mandatory for ingestion.

## Delphix Initiated Backup/External Backup - Streaming Replication Parameters

List of parameters for Delphix initiated backup and external backup with streaming replication

**+ Add**

Delphix Initiated Backup - Single Database Ingestion

Allow Delphix to initiate the logical backup via pg\_dump on the source database.

- d. Click on the **+Add** icon located next to the **Single Database Ingestion method** option.

**Note :**The Add Button provided for Delphix Initiated Backup - Single Database Ingestion is clickable multiple times but should be used ONLY once since the solution is built only to support a single backup path. Providing Multiple Paths will error out the linking process.

The following fields are mandatory for this process.

- i. **Source Postgres Database Name:** Provide the source Postgres database name that needs to be ingested.
- ii. **Source Postgres Database User Name:** Provide the user name of the source Postgres database. The default value is postgres.
- iii. **Source Postgres Database User Password:** Provide the password of the source Postgres database.
- iv. **Source Postgres DB Host:** Provide the source database host address.
- v. **Source Instance Port Number:** Enter the port number for Source Database. The default value is 5432.
- vi. **Postgres Backup Dump Directory:** Provide the directory on the staging host on which backup will be created. This path should exist in the host environment with read and write access to the OS user.
- vii. **Number of Backup Jobs:** Provide the number of parallel jobs to be executed to take backup. The default value is 2.
- viii. **Number of Restore Jobs:** Provide the number of parallel jobs to be executed to restore backup. The default value is 2.
- ix. **(Optional) Staging postgresql.conf config file:** Provide the path to a template Postgres config file that will be used when starting the dSource.

Delphix Initiated Backup - Single Database Ingestion

Allow Delphix to initiate the logical backup via pg\_dump on the source database.

#### Single Database Ingestion method

 Comment Property

Select this option to comment out the provided property name in the configuration file

+ Add

- g. Click **Next**.
6. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
8. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
9. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
10. In the **Summary** tab, review the configuration profile for the dSource.
11. Click **Submit**.

### The dSource Configuration Screen

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations.

### Creating a dSource with Staging Push

For staging push implementation details, see [Staging Push Implementation](#)

#### Procedure

1. Login to the **Delphix Management** application.
2. Select **Manage > Environments**.
3. From the **Databases** tab, select a repository from which you want to create your dSource and click the  icon.
4. In the **Add Database** dialog window, enter the **Name** for your source config and click **Add**.
5. Select your source config and click the **Add dSource** option located to the right.
6. In the **Source** tab, do the following:
  - a. In the **NFS Mount Location** field, enter a mount location on the staging host.

**Data Type**

AppData

NFS Mount Location \*

/tmp/dSource

Mount Location on Staging Host [No spaces allowed]

- b. If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the Prerequisites for Privilege Elevation using DLPX\_DB\_EXEC Scriptsection.

**Note:**

You will currently not be able to update the Privileged OS account after dSource creation. The only way to achieve the change is to recreate the dSource.

If the Environment OS user will be used to create the dSource, make sure you have the following privileges:

- access to the postgres commands
- read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]

- c. Select the checkbox next to the **Use Staging Push** option. Selecting this checkbox allows you to use the Staging Push Flow.
- d. Provide **Staging Instance Port Number**. It must be unique for a given instance. Make sure the port number you have provided on the UI must match the port number in the postgresql.conf file.

**Note:**

The staging push flow database configuration parameters defined in the Config Settings section will be ignored by the Plugin. You will have to take care of these configurations on your own from the backend.

 Use Staging Push

Selecting this option will allow the user to manage the staging database.

Staging Instance Port Number \*

5433

Port number for Postgres staging database

- e. Click **Next**.

7. In the **dSource Configuration** tab, enter a dSource name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
8. In the **Data Management** tab, specify your Staging Environment, User, and Snapshot Parameters. Select the **Resynchronize dSource** checkbox if you want to resynchronize the dSource. Resynchronizing the dSource will force a non-incremental load of data from the source. This operation is similar to creating a new dSource, but avoids duplicating storage requirements and maintains timeflow history. Click **Next**.
9. In the **Policies** tab, apply policy details to the dSource if required, and then click **Next**.
10. In the **Hooks** tab, select a Hook Point and then click **+** to add a script to run at that point. You can define scripts to run at multiple hook points in the process.
11. In the **Summary** tab, review the configuration profile for the dSource.
12. Click **Submit**.

**The dSource configuration screen**

After you have created a dSource, the dSource Configuration tab allows you to view information about it and make modifications to its policies and permissions. In the Datasets panel, select the dSource you wish to examine. You can now choose the configuration tab to see information such as the Source files, Data Management configuration, and Hook Operations.

## Staging push implementation

The Staging Push feature enables you to push data into the Delphix-provided mount point on your own. It is an alternative Delphix dSource data ingestion approach that enables you to push the data in Delphix, which is different from the conventional pull model where Delphix pulls the data.

There are two mechanisms to create dSource on the staging server.

- Pull architecture: The Postgres plugin pulls the data into the Delphix-provided mount location.
- Staging Push architecture: You push the data into the Delphix-provided mount point on your own.

### Staging push implementation details

Staging Push gives you control over some staging database processes. It will give you control of the staging database to ingest data at either the cluster or individual database level. Staging database files will be stored on Delphix storage.

The following ingestion mechanisms are verified:

- Postgres Streaming Replication
- Backups + Logs w/ pg\_basebackup
- Backups + Logs w/ pgbackrest
- Logical Replication and
- pg\_dump and pg\_restore method

 The first snapshot created as a part of dSource creation contains a data directory within the Delphix created mount point. This directory will be empty for the first snapshot.

The first snapshot of the dSource will be empty. In this case, dSource snapshot metadata will contain the information whether the snapshot taken is provisionable or not. If you try to create a VDB from the first snapshot, then the Plugin will error out the operation with a proper error message.

The below steps show how to create a dSource using the Staging Push mechanism.

### dSource Creation

The first snapshot created as a part of dSource creation contains a data directory within the Delphix created mount point. This directory will be empty for the first snapshot. The following snippet shows how the file system appears inside the Delphix-created mount point.

```
[postgres@target Staging_Push]$ tree
├── data

1 directory, 0 files
[postgres@target Staging_Push]$ pwd
/mnt/provision/Staging_Push
```

If you attempt to create a VDB from this snapshot, it will fail with the below error message.

### Subsequent Snapshots

The system user needs to follow the steps and commands below before taking any subsequent snapshots.

1. You must recover the physical backup (pg\_basebackup or pgBackRest) in the data directory or if you are recovering the backups created through pg\_dump then you first need to initialize the Postgres Cluster on the data directory and then you can recover the backup through pg\_restore.
2. While recovering the physical backup, you must make sure that all the tablespaces (if exists) should be present under the mount point only.  
The following screenshot represents what the file system will look like once the recovery is complete.

```
[postgres@target data]$ tree -L 1
.
├── base
├── current_logfiles
├── global
├── log
├── logfile
├── pg_commit_ts
├── pg_dynshmem
├── pg_hba.conf
├── pg_ident.conf
├── pg_logical
├── pg_multixact
├── pg_notify
├── pg_replslot
├── pg_serial
├── pg_snapshots
├── pg_stat
├── pg_stat_tmp
├── pg_subtrans
├── pg_tblspc
├── pg_twophase
├── PG_VERSION
├── pg_wal
├── pg_xact
├── postgresql.auto.conf
├── postgresql.conf
├── postmaster.opts
└── postmaster.pid

18 directories, 9 files
```

3. You can now proceed to take a snapshot and the VDB creation using the new snapshot. It's a pre-requisite for the end-user to stop the cluster before taking a snapshot and start the cluster after successful snapshot. If the cluster is not stopped, then the snapshot operation will fail with an error message.

#### Disable/Delete Operation

For dSource disable and delete operation, it is a pre-requisite for the end-user to stop the cluster before kicking these operations from the UI. If it's not stopped, then the operations will fail with an error message.

#### Resync Operation

If the data directory under the mount path contains any file, then the resync operation will fail with an error message. So, for the resync operation, it is a pre-requisite that the data directory should be empty.

## Working with PostgreSQL snapshots

Taking a snapshot creates a new snapshot entry in the dSource's Timeflow. The plugin-managed dSource allows you to select the parameters before taking the snapshot. These parameters are provided as an input to pre-snapshot and post snapshot functions. On the other hand, in the default snapshot, the parameters are pre-defined in the dSource environment.

### Snapshot (Default)

This section lists the steps to take a snapshot and delete the same.

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the **Camera** icon. Alternatively, click the arrow next to the Camera icon and select **Snapshot (default)**.
5. From the Snapshot dialog, select **Perform Snapshot**.
6. Click **View:** under **Timeflow** to verify the Snapshot you just created.
7. To delete, select the snapshot you just created, and from the Actions menu (...) select **Delete Snapshot**.
8. In the Delete Snapshot dialog, select **Delete**.
9. Click **View:** under **Timeflow** to verify the Snapshot, you just deleted.

## Source sizing implementation for dSource

The Source Sizing feature aligns the data source experience with Delphix database standards that will improve your ingestion reporting experience on the per TB pricing model. This feature enables you to calculate the database size based on whether they are ingested at the PostgreSQL cluster level or database level

### Procedure

When a dSource is created using the staging pull method, the following are the ways to get the database size:

- You can calculate the size of the whole PostgreSQL cluster if the dSource is ingested at the cluster level. Execute the below SQL command to get the size of the whole PostgreSQL Cluster. `SQL >> SELECT SUM(pg_database_size(pg_database.datname)) AS size FROM pg_database;`
- You can calculate the size of the ingested database if the dSource is ingested at the single database level. Execute the below SQL command to get the size of the ingested database. `SQL >> SELECT pg_database_size(pg_database.datname) AS size FROM pg_database WHERE pg_database.datname='<>`

- The source sizing feature is not available for dSources created using the staging push method.
- For this feature to work,
  - The plugin must be able to login to the database or else **None** is displayed.
  - While calculating the size of the cluster, the dataset must have a superuser called **postgres** and should be able to login to the cluster without using password; when logged in, the plugin will connect to the default **postgres** database.

## Provisioning and managing VDBs from PostgreSQL dSources

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment.

From a dSource, you can select a snapshot or point in time to create a VDB. PostgreSQL VDBs each have their own configuration settings as described in the following topics:

- [Provisioning PostgreSQL VDBs: Overview](#)
- [Upgrading PostgreSQL VDBs](#)
- [Provisioning a PostgreSQL VDB](#)
- [Provisioning a PostgreSQL VDB PiT with external logs](#)
- [Rewinding a PostgreSQL VDB](#)
- [Database permissions for provisioned PostgreSQL VDBs](#)

## Provisioning PostgreSQL VDBs: Overview

This topic describes the basic concepts involved with provisioning VDBs from PostgreSQL.

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment, as described in the overview for [Managing environments and hosts](#) and [Overview of requirements for PostgreSQL](#)

From a dSource, you can select a snapshot or point in time to create a VDB. PostgreSQL VDBs each have their own configuration settings as described in [Configuration Settings for PostgreSQL Virtual Databases](#)

For an overview of the high-level components involved in provisioning a PostgreSQL VDB refer to [Setting up PostgreSQL environments: An overview](#)

Once you have provisioned a VDB, you can also take snapshots of it. As with the dSource snapshots, you can find these when you select the VDB in the Datasets panel. You can then provision additional VDBs from these VDB snapshots.

### Dependencies

If there are dependencies on the snapshot, you will not be able to delete the snapshot free space; the dependencies rely on the data associated with the snapshot.

## Upgrading PostgreSQL VDBs

This topic describes how to upgrade a PostgreSQL VDB to a higher version of PostgreSQL.

 Currently, only minor upgrades are supported. For example, from PostgreSQL version 12.2 to 12.7.

### Procedure for VDB In-Place Upgrade

1. Remove any VDB Refresh Policy assigned to the VDB.
2. Upgrade the target PostgreSQL instance.
3. Refresh the target environment.

## Provisioning a PostgreSQL VDB

You can take a new snapshot of the dSource by clicking the Camera icon on the dSource card. Once the snapshot is complete you can provision a new VDB from it. This topic describes how to provision a virtual database (VDB) from a POSTGRES dSource.

### Prerequisites

- You will need to have linked a dSource from a staging instance, as described in [Linking a PostgreSQL dSource](#) or have created a VDB from which you want to provision another VDB
- You should have set up the POSTGRES target environment with the necessary requirements as described in [PostgreSQL support and requirements](#)
- Make sure you have the required Instance Owner permissions on the target instance and environment
- The method for [Database permissions for provisioned PostgreSQL VDBs](#) is decided before the provisioning

### Procedure

1. Navigate to **Manage**, and select **Datasets**.
2. Select a dSource and a snapshot from which you want to provision. Click the provision VDB icon to open the **provision VDB** wizard.
3. Select a target environment from the left pane, and an Installation to use from the dropdown list of available PostgreSQL instances on that environment.
4. Set the **Environment User** to be the Instance Owner.

**Note:**

The picking of instance owner is only possible if you have multiple environment users set on that host.

5. You will see the **Target Configuration** section where you need to specify **NFS Mount Location**.

### Provision Plugin-based VDB

- Target Environment
- **Target Configuration**
- Configuration
- Policies
- Masking
- Hooks
- Summary

#### Target Configuration

Configure the target environment.

NFS Mount Location \*

/tmp/vdb

Mount Location on Target Host [No spaces allowed]

Privileged OS Account (Optional)

This privileged unix username will be used to create the VDB. Leave this field blank if you do not want to use privilege elevation. Note: The unix privileged username should begin with a letter or an underscore, followed by letters, digits, underscores, or dashes. They can end with a dollar sign.

Virtual Postgres Port Number \*

5434

Port number for Postgres target database

#### VDB PiT with External Logs Details

VDB PiT with External Logs Details

+ Add

#### Config Settings

Custom Database-Level config settings

+ Add

- If you want to use Privilege Elevation, provide the **Privileged OS Account** username. Make sure you meet all the requirements described in the [Prerequisite for discovery operation](#) section.

**Note:**

To update the Privileged OS Account after VDB creation, first disable the instance, update the Privileged OS Account, and then enable it.

If the Environment OS user will be used to create the VDB, make sure you have the following privileges:

- access to the the postgres commands
- read+write+execute permissions on the ``unix_socket_directories`` configured in ``postgresql.conf`` [Default directories: ``/var/run/postgresql`` & ``/tmp``]

- Optionally, you can set the database configuration parameters for the VDB using **Config Settings**. Users can disable a configuration parameter by selecting the check box Comment Property. This will comment out the parameter in the `postgresql.conf` configuration file. Click **Next**.

### Config Settings

Custom Database-Level config settings

Property Name \*  
 Delete

Value

Comment Property

Select this option to comment out the provided property name in the configuration file

Property Name \*  
 Delete

Value

Comment Property

Select this option to comment out the provided property name in the configuration file

+ Add

- On the **Configuration** page enter the PostgreSQL VDB name which will be displayed on the UI.
- Select a **Target Group** for the VDB and click the green **Plus** icon to add a new group, if necessary.
- Select a **Snapshot Policy** for the VDB then click **Next**.
- Specify any desired hook operations.
- Review the Provisioning Configuration and Data Management information.
- Click **Submit**.

Once the VDB provisioning has successfully completed, if the source and target instance ids are not the same, you may want to grant secadm and dbadm on the database to the target instance id. Please refer to [Database permissions for provisioned postgresQL VDBs](#) for more information.

## Database permissions for provisioned PostgreSQL VDBs

This topic describes the database permissions on provisioned POSTGRES virtual instances

### PostgreSQL authentication

Authentication is the process by which the database server establishes the identity of the client, and by extension determines whether the client application (or the user who runs the client application) is permitted to connect with the database username that was requested.

PostgreSQL offers a number of different client authentication methods. The method used to authenticate a particular client connection can be selected on the basis of (client) host address, database, and user.

PostgreSQL database user names are logically separate from user names of the operating system in which the server runs. If all the users of a particular server also have accounts on the server's machine, it makes sense to assign database user names that match their operating system usernames. However, a server that accepts remote connections might have many database users who have no local operating system account, and in such cases, there need be no connection between database user names and OS user names.

#### **Delphix postgresQL authentication**

Delphix for PostgreSQL requires that the staging and target hosts must already have the necessary users and authentication systems created/installed on them. Delphix will neither create users nor change database passwords as part of the provisioning process. It is required to have 'trust' as a PostgreSQL authentication mechanism on the source with a target server.

The following section describes some important authentication methods used by PostgreSQL architecture.

### Trust authentication

When trust authentication is specified, PostgreSQL assumes that anyone who can connect to the server is authorized to access the database with whatever database user name they specify (even superuser names). Of course, restrictions made in the database and user columns still apply. This method should only be used when there is adequate operating-system-level protection on connections to the server.

### Password authentication

The password-based authentication methods are md5 and password. These methods operate similarly except for the way that the password is sent across the connection, namely MD5-hashed and clear-text respectively.

PostgreSQL database passwords are separate from operating system user passwords. The password for each database user is stored in the pg\_authid system catalog. Passwords can be managed with the SQL commands [CREATE USER](#) and [ALTER ROLE](#), e.g., `CREATE USER foo WITH PASSWORD 'secret'`. If no password has been set up for a user, the stored password is null and password authentication will always fail for that user.

There are some more authentication mechanism which is less often used, refer to the [Postgresql](#) link embedded for more insights on them.

- [GSSAPI Authentication](#)
- [SSPI Authentication](#)
- [Ident Authentication](#)
- [Peer Authentication](#)
- [LDAP Authentication](#)

- [Certificate Authentication](#)
- [PAM Authentication](#)

- [BSD Authentication](#)

## Rewinding a PostgreSQL VDB

Rewinding a VDB rolls it back to a previous point in its Timeflow and re-provisions the VDB. The VDB will no longer contain changes after the rewind point.

Although the VDB no longer contains changes after the rewind point, the rolled-over Snapshots and Timeflow still remain in Delphix and are accessible through the Command Line Interface (CLI). Refer to [CLI Cookbook: Rolling forward a VDB](#) for instructions on how to use these snapshots to refresh a VDB to one of its later states after it has been rewound.

Delphix clones a new Timeflow from the closest Snapshot older than or equal to the rewind point. This creates a dependency between the new Timeflow and the parent Snapshot and Timeflow. The parent Snapshot and Timeflow cannot be deleted because of this dependency. The VDB must first be refreshed before the parent Snapshot and Timeflow can be removed.

### Prerequisites

To rewind a VDB, you must have the following permissions:

A user with Delphix Admin credentials can perform a VDB rewind on any VDB in the system.

### Procedure

1. Login to the **Delphix Management** application.
2. Under **Datasets**, select the VDB you want to rewind.
3. On the **Timeflow** tab, select the rewind point as a snapshot or a point in time.
4. Click **Rewind**.
5. If you want to use login credentials on the target environment other than those associated with the environment user, click Provide Privileged Credentials.
6. Click **Yes** to confirm.

#### Using TimeFlow Bookmarks

You can use a Timeflow bookmark as the rewind point when using the CLI. Bookmarks can be useful to:

- Mark where to rewind to – for example, before starting a batch job on a VDB
- Provide a semantic point to revert back to in case the chosen rewind point turns out to be incorrect.

For a CLI example using a Timeflow bookmark, refer to [CLI Cookbook: Provisioning a VDB from a timeflow bookmark](#).

## PostgreSQL hook operations

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at `/bin/sh`. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a `bash` binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
```

```
# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

## Shell operation tips

### Using `nohup`

You can use the `nohup` command and process backgrounding from resource in order to "detach" a process from the Delphix Engine. However, if you use `nohup` and process backgrounding, you MUST redirect `stdout` and `stderr`.

Unless you explicitly tell the shell to redirect `stdout` and `stderr` in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either `stdout` or `stderr`. Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your `RunCommand` operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad Examples

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

#### Good Examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs which normally can only be used interactively, such as `ssh`. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Management application and CLI to aid in debugging.

If successful, the script must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of a RunExpect Operation

Start an `ssh` session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
  -re {Password: } {
    send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
  }
  timeout {
    puts "Timed out waiting for password prompt."
    exit 1
  }
}
exit 0
```

## PostgreSQL environment Variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set certain environment variables so that the user-provided script can use them to access the dSource or VDB.

### dSource environment variables

Environment Variable	Description
<code>DLPX_DATA_DIRECTORY</code>	The mount path provided by the user on the UI.
<code>USER</code>	The OS user used to link the dSource.

### VDB environment variables

Environment Variable	Description
<code>DLPX_DATA_DIRECTORY</code>	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
<code>USER</code>	The OS user used to provision the VDB.

## Managing plugin configurations

### Managing log rotation and log level

Delphix PostgreSQL plugin provides a feature that helps users to manage the log rotation for the plugin logs found within the scratch path, located at `<toolkit path>/Delphix_COMMON_<long id>/plugin/postgres-vsdk_<long plugin id>/<os user>_logs/delphix_postgres_debug.log`.

Delphix users can configure the logging mechanism by modifying the below parameters defined in the `dlpx_postgres_config.ini` file that gets created or is already available within the scratch path, located at `<toolkit path>/Delphix_COMMON_<long id>/plugin/postgres-vsdk_<long plugin id>/dlpx_postgres_config.ini`.

This configuration handles the following parameters:

#### Setting maximum size

Delphix users can set the parameter `MAX_FILE_SIZE_KB` available in the `dlpx_postgres_config.ini` file to set the maximum size of the active log file in KB. Once this limit is reached, the plugin will rotate the log. The default/maximum value of this parameter is 10240 KB/10 MB. This parameter accepts only a positive integer value, such as 10240.

#### Setting number of log files to retention

Delphix users can set a retention number for the rotated log files using the parameter `NUM_OF_FILES_TO_KEEP`. The default value of the parameter is 50. That means, the maximum number of rotated log files that will be retained is 50 and each file will be of a size as defined in the `MAX_FILE_SIZE_KB` parameter. If the number of files exceeds this value, then the old files will be deleted in a FIFO order.

#### Setting the log level

Delphix users can set the amount of log being generated on the remote host by defining the `LOG_LEVEL` parameter. Accepted values are **DEBUG, INFO, WARNING, and ERROR**, with **INFO** being the default value.

## Managing PostgreSQL timeouts

### PGCTLTIMEOUT

The `PGCTLTIMEOUT` parameter defines the default limit on the number of seconds to wait for the Postgres startup to complete. This parameter is introduced to compensate for any network latency between the Delphix Engine & the remote host. The default value is set to 600 seconds.

`dlpx_postgres_config.ini`

```
[log_config]
MAX_FILE_SIZE_KB = 10240
NUM_OF_FILES_TO_KEEP = 50
LOG_LEVEL = INFO # Accepted values: DEBUG, INFO, WARNING and ERROR

[database_config]
PGCTLTIMEOUT = 600
```

## SAP ASE environments and data sources

This section covers the following topics:

- [Delphix architecture with SAP ASE](#)
- [Overview of ASE database encryption](#)
- [Quick start guide for SAP ASE](#)
- [SAP ASE support and requirements](#)
- [Managing SAP ASE environments and hosts](#)
- [Linking data sources and Syncing Data with SAP ASE](#)
- [Provisioning and managing VDBs from SAP ASE](#)
- [Backup server best practices](#)
- [SAP ASE hook operations](#)
- [Support for dump history file](#)

## Delphix architecture with SAP ASE

This topic describes the high-level process for adding SAP ASE-supported environments, linking SAP ASE databases to the Delphix Engine, and provisioning virtual databases.

### Diagram of underlying Linking Architecture to support ingestion workflows between SAP ASE-supported Environments and the Delphix Engine.

### Linking architecture between SAP ASE and Delphix engine

The diagram featured above shows a common architecture for SAP ASE-based systems. The diagram shows the infrastructure used to ingest data. (From the above diagram) The workflow starts with a Source Host (Left, which in this example is a Production Database Server), that provides critical data in the form of dump files (used for SnapSync) and transaction logs (used for LogSync).

The Delphix Engine (Bottom), continuously monitors the source database to determine when new dumps are available. When a dump is available, the Delphix Engine will contact the SAP ASE Staging host (Right) via Delphix Session Protocol (DSP). The Staging host will read the dumps from the Source Host and recover them through a Staging Database that is automatically set up on Delphix NFS storage. Once recovery is complete, the backup data

is incorporated into the Delphix dSource as a new snapshot card and is available for use to provision a new virtual or physical database.

**Diagram of underlying provisioning architecture to support VDB provisioning workflows between the Delphix engine and SAP ASE-supported target environments.**

**[-]** If no remote load location (aka Source Host) is configured, dump files must be made available on the staging host via NFS or some other copy mechanism. If no remote load location is configured, the Delphix Engine searches for the files on the staging server. If they are not found, the Delphix Engine cannot load them

SAP ASE provisioning architecture

This diagram is an extension of the previous diagram with the new content showing how Delphix provisions Virtual Databases (VDBs) to a Target Environment. The Delphix Engine (bottom) creates a set of virtual files from a snapshot that becomes the VDB. These files are presented to the Target host (right) via NFS. Delphix uses DSP to communicate with Target and initiates the creation of a new database. Once complete, the VDB is brought online and made available for use.

Environment setup

Target and staging environments for SAP ASE

For SAP ASE-based Delphix Architectures, the Staging Host plays a critical role:

1. Provide the “staging” point in which the Delphix Engine coordinates data ingestion to a dSource by restoring backups to a staging database and creating a dSource from that ingested data.

2. Tracks changes on disk by running validated sync, a process that identifies when new backups are available and initiates the ingestion process if new backups and/or transaction log backups are found.
3. Minimizes touch to production by providing an intermediate host between source databases and Delphix.

**For SAP ASE-based Delphix architectures, the target host has two potential roles:**

1. Host a target environment for provisioning virtual databases (VDBs).

 Staging and Target hosts can be run on a target server, although a dedicated staging server is recommended for optimal performance.

SAP ASE dSources are representations of a Source Database replica on the staging database that runs on a target or staging host. There is no requirement for additional local storage with either host option, as the storage is mounted over NFS from the Delphix Engine. For a deeper, technical discussion, please see the Technical Deep Dive section below.

At Delphix, we refer to the creation and maintenance of this staging database on the staging host as "validated sync," because it prepares the dSource data on the Delphix Engine for provisioning VDBs later on. After the Delphix Engine creates the staging database, it continuously monitors the source database for new transaction log/Full backups (if "truncate log on checkpoint" is active, Delphix will need Full Backups for Validated Sync). When it detects a new transaction log backup, it restores that backup to the staging database. The result is a TimeFlow with consistent points from which you can provision a VDB, and a faster provisioning process, because there is no need for any database recovery during provisioning. If Log Sync is enabled, you may provision a VDB to a point in time, in between snapshots.

When you later provision a VDB, you can specify any environment as a target, including the environment that contains the staging database. However, for best performance, we recommend that you choose a different target environment. The only requirement for the target is:

- It must have an operating system that is compatible with the one running on the validated host.

## Target hosts for ASE

### Container for VDBs

This topic describes the basic concepts involved with provisioning VDBs from SAP ASE dSources or even other SAP ASE VDBs.

A dSource is a virtualized representation of a physical or logical source database. As a virtual representation, it cannot be accessed or manipulated using database tools. Instead, you must create a virtual database (VDB) from a dSource snapshot. A VDB is an independent, writable copy of a dSource snapshot. You can also create VDBs from other VDBs. Once you have provisioned a VDB to a target environment, you can also implement snapshot and retention policies for the VDB, which will determine how frequently Delphix Engine will take a database snapshot and how long the snapshots will be retained for recovery and provisioning purposes.

When provisioning a VDB, Delphix creates the database with the default SAP ASE database options. If the database options have been altered on the source database and you wish for the VDB to reflect these same options, they would need to be altered via a Post-Script or by [Hook Scripts for Automation and Customization](#)

For an overview of the high-level components involved in provisioning an SAP ASE VDB, see [Overview of Provisioning SAP ASE Virtual Databases](#)

## Validated sync and logSync

To run validated sync, a staging environment must be specified to host a staging database for the validated sync process. In this process, the Delphix Engine continuously monitors the source database for new full and transaction

log backups if the source database is using a simple recovery model, and only transaction log backups if using a full recovery model. When it detects a new backup, it restores that backup to the staging database with the storage residing in Delphix. The result is a Timeflow with consistent points from which you can provision a VDB, also known as snapshots.

 If the “truncate log on checkpoint” is set, Delphix will only apply full backups.

Snapshots accumulate over time. To view a snapshot:

1. From the Datasets panel, click the group containing the dSource.
2. Select dSource.
3. Click the Timeflow tab.

Each snapshot is displayed and includes information about the source database, operating system, and time stamp. You can scroll through these cards to select the one you want, or you can enter a date and time to search for a specific snapshot.

Once you have provisioned a VDB, you can also take snapshots of it. As with the dSource snapshots, you can find these when you select the VDB in the Datasets panel. You can then provision additional VDBs from these VDB snapshots.

### **Dependencies**

If there are dependencies on the snapshot, you will not be able to delete the snapshot free space; the dependencies rely on the data associated with the snapshot.

## Overview of ASE database encryption

Beginning with 16.0, SAP ASE supports the Database Encryption feature. The SAP ASE Database Encryption feature encrypts the data at rest, without changing the applications. This encryption can be done on entire databases or only on columns. This ensures that the authorized users access the data and thus prevents the misuse of the data against theft and security breaches.

Data is encrypted with the help of encryption keys. These encryption keys are stored in the database in an encrypted form. You can encrypt an encryption key using a key encryption key (KEK).

In the SAP ASE Database Encryption, column and database encryption uses a symmetric encryption algorithm, which means that the same key is used for encryption and decryption. SAP ASE tracks the key that encrypts the data.

Starting 6.0.8.0, Delphix Engine will support the SAP ASE encrypted databases.

For more information on SAP ASE Database Encryption, see the [SAP ASE Encryption Documentation](#)

## Delphix implementation of database encryption

This topic describes various configurations to support encrypted databases with Delphix. Follow the mandatory steps below on the ASE instance that hosts the staging databases and virtual databases.

1. If the source database is not encrypted already.
  - a. Install the license option ASE\_ENCRYPTION.
  - b. Create a master key that will serve as the KEK.  
Command

```
> create encryption key master with passwd "sybase"
```

- c. If the database is not encrypted already, create the database encryption key and use it.  
Commands

```
> create encryption key <encryption-key-name> for database encryption
> sp_configure "number of worker processes", 2
> alter database <database-name> encrypt with <encryption-key-name>
```

- d. Export the master key and the encryption key to a location that is shared among source, staging, and target hosts. The command-line version of the [ddlgen](#) tool is located at `$SYBASE/$SYBASE_ASE/bin`. You need to find out this location for your instance if it is different.
  - i. `cd $SYBASE/$SYBASE_ASE/bin`
  - ii. `ddlgen -Usa -Psybase -SASE160_SRC -TEK -N master.dbo.master -XOD -O<shared-path>/master_ddl.sql`
  - iii. `ddlgen -Usa -Psybase -SASE160_SRC -TEK -N master.dbo.<key_name> -XOD -O<shared-path>/<key_name>_ddl.sql`
- e. Enable encryption in SAP ASE by executing the below command on the staging/target instance.  
Command

```
> sp_configure 'enable encrypted columns', 1
```

2. Import the keys on the staging and target instances by running the below commands from the directory where the SQL files are present (the shared location between instances) or mention the entire path of the files to be imported.
  - a. `isql -Usa -Psybase -SASE160_TGT -w 220 -i master_key.sql`
  - b. `isql -Usa -Psybase -SASE160_TGT -w 220 -i <key_name>.sql`
3. Set the encryption password by executing the below command on the staging/target instance.  
Command

```
> set encryption passwd "sybase" for key master
```

4. Setup for automatic master key access. Refer [create the master key start-up file](#). In order to avoid issues on the master key password after the reboot of the ASE instance, a master key startup file needs to be created by running the following steps on the staging and the target instance.
  - a. Command

```
> sp_configure 'automatic master key access',1
```

- b. Command

```
> alter encryption key master with passwd 'sybase' add encryption for  
automatic_startup
```

- c. Command

```
> sp_encryption mkey_startup_file,default_location,sync_with_mem
```

- d. Verify if the master key startup file has been successfully created on the instance.  
Command

```
> sp_encryption mkey_startup_file
```

- e. Reboot the ASE instance to get the master key startup file in effect.

If you perform a reboot or plan to perform a reboot on the source host, then you would need to repeat step 4 on the source host as well. By doing so, you don't need to set the master key password again after reboot.

## Quick start guide for SAP ASE

This quick start guide, which is excerpted from the larger User Guide, is intended to provide you with a focused overview of working with SAP ASE database objects in the Delphix Dynamic Data Platform. It does not cover advanced configuration options. It does not cover advanced configuration options or best practices for performance. It assumes that you are working in a Lab/Dev setting and attempting to quickly test Delphix Engine functionality. It assumes you will use the VMware Hypervisor.

### Overview

In this guide, we will walk through deploying a Delphix Engine, starting with configuring SAP ASE Source and Target environments. We will then create a dSource, and provision a VDB. A detailed list can be referred to in the [Network and Connectivity Requirements for SAP ASE Environments](#) section of the manual.

For purposes of the QuickStart, you can ignore any references to Replication or Masking, such as the engines shown in the diagram below.

Delphix stays in sync with source databases by monitoring the ASE backup server log. When it sees a new database dump or transaction log has been created, it attempts to load it into the ASE staging instance.

Color	Supported?
Y	Yes
N	No

Validated sync Mode	SnapShot for FULL BACKUP	SnapShot for TLOGS	Point-in-Time Restore
truncate log on chkpt = true	Y	Y	Y
truncate log on chkpt = false + LogSync truncate log on chkpt = false	N	Y	N
truncate log on chkpt = true + Log Sync	Y	N	N
truncate log on chkpt = false + LogSync	N	Y	Y

Before proceeding with setting up environments, decide where the databases will be located relative to the ASE staging instance. In the following diagram, we have two ASE hosts (production and staging).

If the database dumps (or transaction logs) are available locally to the staging Backup Server, Delphix considers them “local”. Whereas if they are available to a Backup Server on production, they are “remote”. If the files will be local to the staging server, there are many options to get them from the production host to the staging host including but not limited to:

- Sharing the directory on the production host over NFS to the staging host.
- Using Network Attached Storage (NAS) to replicate the files.
- Using scp to copy the files from one host to the other.

If the files are only available on the production host, Delphix will login to the ASE staging instance and issue the “LOAD DATABASE” command using the remote server syntax (for example LOAD DATABASE pubs2 FROM "/dumps/pubs2.full.9\_5\_16" AT Prod\_BS).

## Deploy OVA on VMware

Use the Delphix-supplied OVA file to install the Delphix Engine. The OVA file is configured with many of the minimum system requirements. The underlying storage for the install is assumed to be redundant SAN storage.

1. Download the OVA file from <https://download.delphix.com>. You will need a support login from your sales team or a welcome letter.
  - a. Navigate to the Delphix Product Releases/<Current Version>/Appliance Images page.
  - b.
2. Login using the vSphere client to the vSphere server (or vCenter Server) where you want to install the Delphix Engine.
3. In the vSphere Client, click **File**.
4. Select **Deploy OVA Template**.
5. Browse to the OVA file.
6. Click **Next**.
7. Select a **hostname** for the Delphix Engine. This hostname will also be used in configuring the Delphix Engine network.
8. Select the **data center** where the Delphix Engine will be located.
9. Select the **cluster** and the **ESX host**.
10. Select one (1) **data store** for the **Delphix OS**. This datastore can be **thin-provisioned** and must have enough free space to accommodate the 127GB comprising the Delphix operating system.
11. Select four (4) or more **data stores** for Database Storage for the Delphix Engine. The Delphix Engine will stripe all of the Database Storage across these VMDKs, so for optimal I/O performance, each VMDK must be equal in size and be configured **Thick Provisioned - Eager Zeroed**. Additionally, these VMDKs should be distributed as evenly as possible across all four SCSI I/O controllers.
12. Select the **virtual network** you want to use. If using multiple physical NICs for link aggregation, you must use vSphere NIC teaming. Do not add multiple virtual NICs to the Delphix Engine itself. The Delphix Engine should use a single virtual network. For more information, see [Optimal Network Architecture for the Delphix Engine](#)
13. Click **Finish**. The installation will begin and the Delphix Engine will be created in the location you specified.
14. Once the installation has completed, power on the Delphix Engine and proceed with the initial system configuration as described in [Setting Up Network Access to the Delphix Engine](#)

**i** If your source database is 4 TB, you probably need 4 TB of storage for the Delphix Engine. Add at least 4 data disks of similar size for the Delphix VM. For example: for a source database of 4 TB, create 4 VMDKs of 1 TB each.

**i** For a full list of requirements and best practice recommendations, see [Virtual Machine Requirements for VMware Platform](#)

## Setup network access to Delphix engine

1. Power on the Delphix Engine and open the Console.

2. Wait for the Delphix Management Service and Delphix Boot Service to come online. This might take up to 10 minutes during the first boot. Wait for the large orange box to turn green.
3. Press any key to access the sysadmin console.
4. Enter `sysadmin@SYSTEM` for the username and `sysadmin` for the password.
5. You will be presented with a description of available network settings and instructions for editing.

Delphix Engine Network Setup To access the system setup through the browser, the system must first be configured **for** networking in your environment. From here, you can configure the primary **interface**, DNS, hostname, and **default** route. When DHCP is configured, all other properties are derived from DHCP settings. To see the current settings, run `"get."` To change a property, run `"set =."` To commit your changes, run `"commit."` To exit **this** setup and **return** to the standard CLI, run `"discard."`

defaultRoute IP address of the gateway **for** the **default** route -- **for** example, "1.2.3.4." dhcp Boolean value indicating whether DHCP should be used **for** the primary **interface**. Setting **this** value to "true" will cause all other properties (address, hostname, and DNS) to be derived from the DHCP response dnsDomain DNS Domain -- **for** example, "delphix.com" dnsServers DNS server(s) as a list of IP addresses -- **for** example, "1.2.3.4,5.6.7.8." hostname Canonical system hostname, used in alert and other logs -- **for** example, "myserver" primaryAddress Static address **for** the primary **interface** in CIDR notation -- **for** example, "1.2.3.4/22" Current settings: defaultRoute: 192.168.1.1 dhcp: false dnsDomain: example.com dnsServers: 192.168.1.1 hostname: Delphix primaryAddress: 192.168.1.100/24

6. Configure the `hostname` . If you are using DHCP, you can skip this step.

```
delphix network setup update *> set hostname=<hostname>
```

**Note:** Use the same `hostname` you entered during the server installation.

7. Configure DNS. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set dnsDomain=<domain> delphix network setup update *> set dnsServers=<server1-ip>[,<server2-ip>,...]
```

8. Configure either a static or DHCP address.  
DHCP Configuration

```
delphix network setup update *> set dhcp=true
```

Static Configuration

```
delphix network setup update *> set dhcp=false delphix network setup update *> set primaryAddress=<address>/<prefix-len>
```

**Note:** The static IP address must be specified in CIDR notation (for example, `192.168.1.2/24` )

9. Configure a default gateway. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set defaultRoute=<gateway-ip>
```

10. Commit your changes. Note that you can use the `get` command prior to committing to verify your desired configuration.

```
delphix network setup update *> commit Successfully committed network settings.
Further setup can be done through the browser at: http://<address> Type "exit"
to disconnect, or any other commands to continue using the CLI.
```

11. Check that you can now access the Delphix Engine through a Web browser by navigating to the displayed IP address, or hostname if using DNS.
12. Exit setup.

```
delphix> exit
```

## Setting up the Delphix engine

Once you set up the network access for Delphix Engine, navigate to the Delphix Engine URL in your browser for server setup.

The welcome screen below will appear for you to begin your Delphix Engine setup.

### Virtualization Setup

**Welcome**

Choose engine type to setup:

- Virtualization
- Masking

This wizard will step you through the setup. During this process you will complete the following:

- Create your password for the default "sysadmin" user
- Set the system time
- Configure network and services
- Configure the storage pool
- Configure proxies, SMTP, and LDAP (these are optional)
- Register your software

After setup is complete, you will have two administrators defined:

- The system administrator, "sysadmin" with the password you defined. This will be the system administrator for the instance.
- The engine administrator, "admin" with the password you defined. This is typically a DBA who will administer all the data managed by the instance.

When setup is complete, log in as engine administrator to begin using your engine.

The setup procedure uses a wizard process to take you through a set of configuration screens:

- Administrators
- Time
- Network
- Network Security
- Storage
- Outbound Connectivity

- Authentication
- Network Authorization
- Registration
- Summary

1. Connect to the Delphix Engine at `http://<Delphix Engine>/login/index.html#serverSetup` The **Delphix Setup** application will launch when you connect to the server. Enter your **sysadmin** login credentials, which initially defaults to the username **sysadmin**, with the initial default password of **sysadmin**. On first login, you will be prompted to change the initial default password.
2. Click **Next**.

## Administrators

The Delphix Engine supports two types of administrators:

- System Administrator (**sysadmin**) - this is the engine system administrator. The sysadmin password is defined here.
- Engine Administrator (**admin**) - this is typically a DBA who will administer all the data managed by the engine.

On the Administrators tab, you set up the sysadmin password by entering an email address and password. The details for the admin are displayed for reference.

The default domain user created on Delphix Engines from 5.3.1 is known as **admin** instead of `delphix_admin`. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling `delphix_admin`.

## System Time

The engine time is used as the baseline for setting policies that coordinate between virtual databases and external applications.

Choose your option to set up system time in this section. For a Quick Start, simply set the time and your timezone. You can change this later.

## Network

The initial out-of-the-box network configuration in the OVA file is set to use a single VMXNET3 network adapter.

You have already configured this in the initial configuration. Delphix supports more advanced configurations, but you can enable those later.

## Storage

You should see the data storage VMDKs or RDMs you created during the OVA installation. Click **Next** to configure these for data storage.

## Serviceability

Choose your options to configure serviceability settings.

For a Quick Start, accept the defaults. You can change this later.

## Authentication

Choose your options to configure authentication services.

For a Quick Start, accept the defaults. You can change this later.

## Registration

If the Delphix Engine has access to the external Internet (either directly or through a web proxy), then you can auto-register the Delphix Engine:

1. Enter your **Support Username** and **Support Password**.
2. Click **Register**.

If external connectivity is not immediately available, you must perform manual registration.

1. Copy the **Delphix Engine registration code** in one of two ways:
  - a. Manually highlight the registration code and copy it to clipboard. Or,
  - b. Click **Copy Registration Code to Clipboard**.
2. Transfer the Delphix Engine's registration code to a workstation with access to the external network Internet. For example, you could e-mail the registration code to an externally accessible e-mail account.
3. On a machine with access to the external Internet, please use your browser to navigate to the Delphix Registration Portal at <http://register.delphix.com>.
4. Login with your Delphix support credentials (username and password).
5. Paste the **Registration Code**.
6. Click **Register**.

 Although your Delphix Engine will work without registration, we strongly recommend that you register each Delphix Engine as part of the setup. Failing to register the Delphix Engine will impact its supportability and security in future versions.

To regenerate the registration code for a Delphix Engine please refer to, [Regenerating the Delphix Engine Registration Code](#). Delphix strongly recommends that you regenerate this code and re-register the engine regularly to maximize the Support Security of the Delphix Engine. Delphix recommends doing this every six months.

## Summary

The final summary tab will enable you to review your configurations for System Time, Network, Storage, Serviceability, and Authentication.

1. Click the **Back** button to go back and to change the configuration for any of these server settings.
2. If you are ready to proceed, then click **Submit**.
3. Click **Yes** to confirm that you want to save the configuration.
4. Click **Setup** to acknowledge the successful configuration.
5. There will be a wait of several minutes as the Delphix Engine completes the configuration.

## Requirements for SAP ASE hosts and databases

In order to begin using SAP ASE environments with Delphix, you will need to configure the source and target hosts with the requirements described on this page.

### SAP ASE source host requirements

There must be an operating system user, such as `delphix_os`, that meets the following requirements:

- The `$SYBASE` environment variable is defined for non-interactive shells (such as via the `.bashrc` configuration file).
  - Set the `PermitUserEnvironment` configuration parameter to "yes" in the `sshd_config` file
  - Add the variable to the user's `.ssh/environment` file
  - Restart the SSH daemon

- To test this requirement:

```
ssh delphix_user@ase_hostname env | grep SYBASE
```

- Can login to the source host via SSH (TCP port 22)
- Delphix requires superuser permission to run **pargs** in order to discover Solaris ASE instances. For more information, see [Sudo Privilege Requirements for SAP ASE Environments](#).
- Designating the Delphix operating system user's primary group to be the same as the ASE instance's means the file system permissions can be more restrictive and is a better security practice than granting world read access to the toolkit or the backup files. If the target host is used to host the staging databases, consider the following:
  - If you don't add the Delphix operating system user to the ASE instance owner's group, greater permissions will need to be **granted to the backup files to ensure read access to the dumps and/or transaction logs**. Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment).
  - If you sync Delphix with a dSource by asking ASE to create a new backup, the ASE instance owner will need the **write permission to the toolkit** (or the mount point if you use the CLI to specify a directory other than the toolkit). Delphix will issue the "DUMP DATABASE" command to write to the staging database's "temp" directory which is mounted on the staging host.
  - Has **write permission for the mount-point directory** (by default the toolkit directory but can be a separate mount point specified in the command line interface).
- There must be a directory on the source host where you can install the Delphix platform toolkit, for example: /var/opt/delphix/Toolkit
  - The delphix\_os user must own the directory
  - The directory must have permissions 0770, for example, -rwxrwx---. However, you can also use more permissive settings.
  - The directory should have 256MB of available storage.

## Source database requirements

When adding a source ASE environment to Delphix, you may use a single login to discover the ASE instances and link the source databases OR you may use a single login to discover all of the ASE instances and separate logins to link each dSource.

- Delphix uses a single database user for the discovery of all ASE instances and their databases for each environment added to Delphix.
  - The discovery database user (delphix\_disc for example) must have SELECT privileges on the following tables for each ASE instance on the source host:
    - **sysdatabases**
    - **sysservers**
    - **syslisteners**
    - **sysconfigures**
    - **syscurconfigs**
- Another user must be specified when linking each dSource (delphix\_link for example) that has SELECT privileges on the above tables.
  - If you will select New Full Backup when linking, this user must also have privileges to take a new full database dump of the source database. For more information about linking options, see [Linking an SAP ASE Data Source](#).
  - The link database user can be different for each instance and database on the source host.

- If the source database is resized and trunc log on chkpt is disabled, take a transaction log dump immediately after the resize operation completes. If trunc log on chkpt is enabled, take a full database dump immediately after the resize operation completes. If multiple resizing operations are performed without taking transaction log dumps between each operation it may be necessary to manually sync the dSource with a new full database dump for Delphix to be able to continue ingesting source database dumps.

## Target host requirements

- The operating system on the target environment must be the same as, or binary compatible with, the operating system on the source environment.
- As the Delphix Engine supports both NFSv3 and NFSv4 for mounting target host filesystems, the prerequisite packages that support NFSv3 or NFSv4 client communication are required for normal operation, and the required services to support NFS client communications (including file locking) must be running. This includes:
  - a. portmapper / rpcbind
  - b. status daemon (rpc.statd)
  - c. NFS lock manager (rpc.lockd/lockmgr)
- The SAP ASE major version on the target environment must be the same as the version on the source environment. However, EBF/SP version on target environment can be different. If the target is used as a staging server, the ASE major version must be the same. The only caveat is for ASE 15.7 - where the source and staging patch levels must both be either any version below SP64 or both be any version above SP100.
- There must be an operating system user, such as delphix\_os, that meets the following requirements:
  - a. Set the PermitUserEnvironment configuration parameter to "yes" in the sshd\_config file
  - b. Add the variable to the user's .ssh/environment file
  - c. Restart the SSH daemon
  - d. The \$SYBASE environment variable is set for non-interactive shells (such as via the .bashrc configuration file). Set the variable as follows:
  - e. To test this requirement:

```
ssh delphix_user@ase_hostname env | grep SYBASE
```

- Can login to the target host via Secure Shell (SSH)
- Can login to ASE instances using isql with LANG=C set
- Designating the Delphix operating system user's primary group to be the same as the ASE instance's means the file system permissions can be more restrictive and is a better security practice than granting world read access to the toolkit or the backup files. If the target host is used to host the staging databases, consider the following:
  - If you don't add the Delphix operating system user to the ASE instance owner's group, greater permissions will need to be **granted to the backup files to ensure read access to the dumps and/or transaction logs**. Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment).
  - If you sync Delphix with a dSource by asking ASE to create a new backup, the ASE instance owner will need **write permission to the toolkit** (or the mount point if you use the CLI to specify a directory other than the toolkit). Delphix will issue the "DUMP DATABASE" command to write to staging database's "temp" directory which is mounted on the staging host.
  - Has **write permission for the mount-point directory** (by default the toolkit directory but can be a separate mount point specified in the command line interface).
- The following permissions are usually granted via sudo authorization of the commands. See [Sudo Privilege Requirements for SAP ASE Environments](#) for further explanation of this requirement, and [Sudo File Configuration Examples for SAP ASE Environments](#) for example file configurations.

- a. Permission to run **mount** and **umount** as super-user.
  - b. On Solaris, permission to run **paragon** Solaris
  - c. On AIX, permission to run the **nfs** command as super-user.
  - d. (Optional) On AIX and Linux, permission to run **psas** super-user.
  - e. Disable **ttty** for the delphix\_os user for mount and umount.
- There must be a directory on the source host where you can install the Delphix platform toolkit, for example: /var/opt/delphix/Toolkit
    - The delphix\_os user must own the directory
    - The directory must have permissions 0770, for example, -rwxrwx--. However, you can also use more permissive settings.
    - The directory should have 1GB of available storage
    - Avoid using the home directory of the delphix\_os user
    - If you intend to use the LogSync feature, it is recommended to make the toolkit directory as short as possible to keep the full path to the transaction log file names under ASE's 127 character limit. For example, create the toolkit directory as /tk. Alternatively, link the dSource using the command line interface and specify the "[mountBase](#)" parameter to mount the staging database's devices under a directory following your own naming convention.

## Target database requirements

- There must be a database user, such as delphix\_db, with the **sa\_role** on each instance on the target environment
- The database user such as delphix\_db for any staging instances must also have the **sybase\_ts\_role**
- If the target host will be used as a staging target environment, at least one of the following two options must be configured:
  - You must use **sp\_addserver** to add the staging ASE instance's Backup Server to **syservers** on the source ASE instance (so that remote database dump/load works)
  - OR
  - Full and transaction dump files from the source database must be available locally to the staging database (over NFS, replication, scp, etc.)

## Specific ASE tuning recommendations

- In ASE 15.7 SP60 and higher, there is a configuration parameter named "**enable large pool for load**". ASE automatically tunes the caches for recovery on reboot, but does not do this for load database and load transaction recovery, since it could impact other databases on a production server. Delphix recommends that the staging ASE instance be separate from the ASE production instance and ASE instances hosting VDBs so enabling this parameter should have **a beneficial impact on performance for the ASE staging instance**.
- Specify the "**relaxed**" strategy for replacing the cache in the default data cache (**sp\_cacheconfig 'default data cache', relaxed**) in the ASE staging instance. Since the mount/unmount process invalidates the pages anyway, the page chain is really just unneeded overhead on the staging server.
- Staging and target ASE instances should have disk mirroring disabled.

**sp\_configure "disable disk mirroring"** – run value should be 1, which is the default. If it is 0, change it using **sp\_configure "disable disk mirroring", 1** – this parameter is static so the ASE instance must be restarted for this change to take effect.

- Delphix will mirror the number of devices used on the source database for the staging database (dSource) and each VDB created from that source database. The number of devices parameter should be scaled appropriately based on the max number of virtual databases that will be provisioned to the ASE instance. This parameter can be changed using: **sp\_configure "number of devices", .**

- i** ASE 15.7.0 SP100 and later releases support the shrink command. In some cases, Delphix must increase the number of devices used for databases if this command is used. Delphix creates a minimum of the same number of devices as the source database for the staging database (dSource) and each VDB and will add more devices for every 4TB of fragment holes. See SAP ASE issue [CR#799273](#) for additional details.

To support multiple VDBs and the staging databases, you may need to increase the parameter number **of alarms**.

- i** Delphix uses ASE operations that use alarm structures such as **MOUNT** and **UNMOUNT**. The number of alarms limits the number of these operations which can be run concurrently. Various ASE instance failures can occur if the available alarm structures are exhausted. The amount of memory consumed by increasing the number of alarm structures is small. Delphix recommends that the **number of alarms** value is increased to at least 4096.

## Adding SAP ASE source and target environments

1. Log in to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. From the **Actions (...)** menu select **Add Environment**.
5. In the **Host and Server** tab window, select **Unix/Linux**.
6. Select **Standalone Host**.
7. Click **Next**.
8. Enter a **Name** for the environment.
9. Enter the **Host IP** address.
10. For NFS Addresses (Optional): Enter one or more comma-separated **IP Address/Hostname**  
**Note:** If specified, Delphix Engine only allows NFS requests (mount, etc) originated from IP Addresses specified for the host.
11. Enter the **SSH** port. The default value is **22**.
12. Select a **Login Type**. — Username and Password - enter the OS username and password — Username and Public Key - enter the OS username. — Password Vault - select from an existing Enterprise Password Vault

### Using public key authentication

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

- a. Select **Public Key** for the **Login Type**.
- b. Click **View Public Key**.
- c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See [Option 2 in this CLI Cookbook article](#) for instructions

13. For **Password Login**, click **Verify Credentials** to test the username and password.

14. Enter a **Toolkit Path**. The toolkit directory stores scripts used for Delphix Engine operations. It must have a persistent working directory rather than a temporary one. The toolkit directory will have a separate subdirectory for each database instance. The toolkit path must have 0770 permissions.
15. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
16. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
17. Click the **Discover SAP ASE** checkbox.
18. Click **Next**.
19. In the Summary, tab confirm your selections.
20. Click **Submit**.

## ASE manual discovery

When an environment is added, Delphix discovers your ASE instances. Manual discovery allows users to add instances that were not automatically discovered. This feature is currently only supported via the CLI.

This topic describes how to use CLI commands to manually add ASE repositories to an SAP ASE environment. Discovery is the process by which the Delphix platform identifies data sources and data dependencies on a remote environment. ASE repository discovery is done automatically when an environment is added to the Delphix platform or when an already added environment is refreshed. In some cases, automatic discovery does not discover all of the repositories in an SAP ASE environment. These repositories may be added using manual discovery.

Unlike automatically discovered instances, manually discovered instances are not automatically deleted if the environment is refreshed when the instance isn't running. Manually discovered instances are not updated during an environment refresh either. So for example, if you upgrade ASE to a new version or change the listener port, you must manually update the repository.

To manually discover an ASE repository you will need to:

- Add the environment to Delphix
- Use CLI to manually discover a repository

## Creating an ASE environment

Please refer to [Adding an SAP ASE Environment](#) for detailed steps.

## Manually discovering a repository

 In the following example, we are using **sc-dev3.dc2** as our example environment.

1. Log into CLI and cd to repository menu:

```
$ ssh delphix_admin@sc-dev3.dc2
Password:
sc-dev3.dc2> cd repository
sc-dev3.dc2 repository>
```

2. Add (manually discover) an ASE repository instance:

**Note:** The values used in the following code block are specific to the example instance we are adding.

```
sc-dev3.dc2 repository> create
sc-dev3.dc2 repository create *> ls
```

```

Properties
  type: ASEInstance
  credentials: (unset)
  dbUser: (unset)
  environment: (required)
  installationPath: (required)
  instanceName: (required)
  instanceOwner: (required)
  ports: (required)
  version: (unset)
sc-dev3.dc2 repository create *> set credentials.password=sybase
sc-dev3.dc2 repository create *> set dbUser=sa
sc-dev3.dc2 repository create *> set environment=sc-rhel64-sybase-ase-0
sc-dev3.dc2 repository create *> set installationPath=/opt/sybase/15-7
sc-dev3.dc2 repository create *> set instanceName=ASE1570_S1
sc-dev3.dc2 repository create *> set instanceOwner=sybase
sc-dev3.dc2 repository create *> set ports=5100
sc-dev3.dc2 repository create *> ls
Properties
  type: ASEInstance
  credentials:
    type: PasswordCredential (*)
    password: ***** (*)
  dbUser: sa (*)
  environment: sc-rhel64-sybase-ase-0 (*)
  installationPath: /opt/sybase/15-7 (*)
  instanceName: ASE1570_S1 (*)
  instanceOwner: sybase (*)
  ports: 5100 (*)
  version: (unset)
sc-dev3.dc2 repository create *> commit
`ASE_INSTANCE-22
sc-dev3.dc2 repository>

```

## Updating a repository

Adding onto the above, the following example illustrates updating an ASE instance's version after upgrading ASE:

```

sc-dev3.dc2> repository
sc-dev3.dc2 repository> select ASE1570_S1
sc-dev3.dc2 repository 'ASE1570_S1'> update
sc-dev3.dc2 repository 'ASE1570_S1' update *> set version="15.7 SP138"
sc-dev3.dc2 repository 'ASE1570_S1' update *> ls
Properties
  type: ASEInstance
  credentials:
    type: PasswordCredential
    password: *****
  dbUser: sa
  installationPath: /opt/sybase/15-7
  instanceOwner: sybase

```

```

linkingEnabled: true
ports: 5100
provisioningEnabled: true
servicePrincipalName: (unset)
staging: false
version: 15.7 SP138 (*)
sc-dev3.dc2 repository 'ASE1570_S1' update *> commit

```

Be careful when setting the version string. Make sure that it matches output as displayed by the "select @@version" query all the way out to the patch level (PL). For example "15.7 SP138" or "16.0 SP02 PL01".

## Enable linking and provisioning for SAP ASE environments

This topic describes how to enable and disable provisioning and linking for SAP ASE databases.

Before a database can be used as a dSource, you must first make sure that you have enabled linking to its SAP ASE instance. Similarly, before you can provision a VDB to a target database, you must make sure that you have enabled provisioning to its SAP ASE instance.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **Databases** tab.
5. Click the **pencil** icon located next to the database **Installation Details**.
6. Select the **Allow Provisioning** checkbox to enable provisioning, deselect the checkbox to disable provisioning.
7. Click **show details** for the database.
8. Slide the button next to **Allow Linking** to **On** or **Off** to enable or disable linking.

## Linking an SAP ASE data source

The dSource is an object that the Delphix Virtualization Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools. For an overview of all dSource related actions, please visit [Managing Data Sources](#). Delphix Virtualization for SAP ASE databases leverages backup-based ingestion, which means that Delphix will look for, or sometimes initiate the creation of, a backup through your SAP ASE backup server. From there, the backup is restored on a staging server and the staging copy is then ingested into Delphix. See [Delphix Architecture with SAP ASE](#) for more information.

When linking a dSource from an SAP ASE source database, Delphix offers several different methods of capturing backup information:

- ASE Managed Backups, where the SAP ASE source database schedules and initiates backups. This method supports various backup types which include:
  - Full backups
  - Transaction log backups (with LogSync disabled)
  - Transaction log backups (with LogSync enabled)
- Delphix Managed Backups, where the Delphix Engine schedules and initiates the backups from the source database, and captures them.

## ASE managed backups

Further contextual information on the various backup types (listed above):

- Full Backups - A snapshot will be created on the Delphix Timeflow for each Full backup.
- Transaction log backups (with LogSync disabled) - A snapshot will be created on the Delphix Timeflow for each transaction log backup.

#### Transaction Logs

Transaction logs are not collected if:

- a) there are gaps in the sequence of log backups (a break in the “log chain”).
- b) the available log backups do not include any changes since the last successful Delphix snapshot.

Transaction log backups (with LogSync enabled) - A snapshot will be created on the Delphix Timeflow for each transaction log backup. In addition, point-in-time provisioning will be an available option if you would like to provision from any point in between snapshots.

#### Log Files

Log files consume additional space on the Delphix Engine and are managed according to the defined retention policy for logs.

## Delphix managed backups

When the checkbox for Delphix Managed Backups is selected, the Delphix Engine will initiate a full backup of the source database for the initial load of the dSource. Thereafter, the Delphix Engine will initiate full backups of the source database using the schedule specified by the selected SnapSync Policy. If you select the None policy, the Delphix Engine will not automatically initiate a full backup, but you can initiate them manually using the snapshot (camera) icon.

Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment)

## Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Click the plus icon and select **Add dSource**.  
**Note:** Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment).
4. In the **Add dSource** wizard, select the source environment with the correct environment-based user.
5. Enter your login credentials for the source database and click **Next**.
6. Enter a name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. Select the **Data Management** settings needed, as described in [Data Management Settings for ASE Data Sources](#).
8. From the **Data Management** tab under the **Initial Load** option, select and enter any **additional settings** needed. There are three options for the initial load of the dSource:
  - a. If the source ASE instance resides on the same server as the staging ASE instance, the staging database's NFS mounted "temp" directory will be present for the source database to write to in response to the "DUMP DATABASE" command.
  - b. If the source and staging ASE instances are configured to allow remote access to the backup servers and the dSource is linked using the Remote Server option as described below. Delphix will then issue the "DUMP DATABASE" command and append the "AT <staging\_backup\_server\_name>" clause so that the dump is written to the staging backup server.

- c. (Recommended) **New Full Backup** - Lets Delphix create a new full backup file and load it. Note - that when Delphix creates the backup, it is moved to Delphix's NFS-mounted storage located on the stage host rather than. The backup will be located in the "temp" directory and will be deleted once the Delphix Engine has restored the backup and created a dSource from the restored staging database. This means that this option will work under two scenarios:
  - d. Most Recent **Existing Full Backup** – Find the most recent existing full backup file in the Backup Location and load it.  
**Note:** If Dump History is not active on the Source Database: Choosing this option can delay completion of the dSource link as Delphix attempts to find and catalog every single backup listed in the source database's backup server log file.
  - e. Specific **Existing Full Backup** – Specify which backup files in the Backup Location you want to load. Choosing this option is much faster because Delphix will skip directly to loading the desired backup and only start to search for and catalog backups in the background after the linking of the source database has completed.  
**Note:** When using a dump taken with the deprecated compression syntax, select the Specific Existing Full Backup option for Initial Load and, for each stripe, type compress::<file name> into the text box.
9. Select the Staging environment and ASE instance that will be used to manage the staging database used for validated sync of the dSource.
  10. Select any policies for the new dSource.
  11. Click **Next**, then specify any pre-hook and post-hook scripts.
  12. Review the dSource Configuration and Data Management information, and click **Submit** to begin provisioning the VDB.

## Provisioning an SAP ASE VDB

### Procedure

1. In the Datasets panel on the left-hand side, click the group containing the dSource or VDB from which you want to provision.
2. Click the **Timeflow** tab.
3. Select a snapshot or open LogSync timeline to provision by a specific log or point in time.
  - Find more detail about initial provisioning options in the section 'Provisioning by Snapshot or LogSync' below.
4. Click to open the Provision VDB wizard, and select a compatible Target Environment for the new ASE VDB
5. Review the information presented for Target Configuration and edit as necessary.
6. Select a Snapshot Policy for the VDB.
7. (Optional) - Selective Data Distribution - After policies, there is a masking option.
8. Enter any operations that should be run in the Hooks page. These scripts can be managed after provision in the VDB's configuration page.

When provisioning starts, you can review the progress of the job by selecting the VDB and clicking on the Status tab, or by selecting Manage/Dashboards and viewing the Job History panel. Alternatively, you could see this in the Actions Sidebar. When provisioning is complete, the VDB will be included in the group you designated and listed in the Datasets panel. If you select the VDB in the Datasets panel and click the Configuration tab, you can view information about the database and its Data Management settings.

### Provisioning by snapshot or LogSync

When provisioning by Snapshot, you can provision to the start of any particular snapshot by time.

Provisioning by snapshot/time	description
Provisioning By Snapshot	You can provision by using a Snapshot. In that case, a new VDB will be provisioned to the database state as of the Snapshot.
Provision by Time	If you have enabled Log Sync, you can provision a new database to a point in time. You can select a snapshot and then using time entry fields, specify a Point in Time. Delphix will use the selected snapshot to restore the VDB and use the log files to roll forward the VDB to the selected time.

## Configuration settings for ASE virtual databases

Each VDB has its own data management settings, found during the provisioning workflow as well as in the configuration page for that VDB. When you create a SAP ASE VDB, Delphix copies most configuration settings from the dSource and uses them to create the VDB. However, you can customize these with the following settings:

Setting	Explanation
Recovery Model	The current recovery model of the source database. This field will auto-populate with information from the dSource.
Auto VDB Restart	Enabling this option will automatically restart this VDB whenever its target host is rebooted.

## Automatic VDB restart on target server after reboot

The Delphix platform now automatically detects whether a target server has been rebooted, and proactively restarts any VDB on that server that was previously up and running. This is independent of the data platform. It is done as if you realized a target server was restarted and issued a start command from the Delphix platform. This feature is compatible with Self-Service ordering dependencies and is limited to non-clustered VDBs.

To enable automatic restart, complete the following steps:

- When provisioning a new VDB in the VDB Provisioning wizard, check the **Auto VDB Restart** box.

Once the VDB has been provisioned, you will be able to turn **Automatic VDB Restart** on.

1. In the **Datasets** panel, select the VDB.
2. Select the **Configuration** tab.
3. Select **Source** sub-tab.
4. Select **Database edit**.

## Next steps

Congratulations! You have provisioned your first virtual database!

Now, perform some simple functional tests with your application. You can connect your app to the VDB using standard TNS/JDBC techniques. Delphix has already registered the VDB for you on the target listener.

We suggest the following next steps:

1. Drop a table and use the VDB Rewind feature to test the recovery of your VDB.
2. Take a snapshot of your dSource and refresh your VDB to quickly get fresh production data.
3. Provision a new VDB from your VDB to test sharing data quickly with other teams.
4. Mask your new VDB to protect sensitive data. Provision new VDBs from that masked VDB to quickly provide safe data to development and QA teams.

## SAP ASE support and requirements

In order to begin using SAP ASE environments with Delphix, you will need to configure the source and target hosts with the requirements described in this section.

This section covers the following topics:

- [SAP ASE support matrix](#)
- [Requirements for SAP ASE environments and databases](#)
- [Network and connectivity requirements for SAP ASE environments](#)
- [Sudo privilege requirements for SAP ASE environments](#)
- [Sudo file configuration examples for SAP ASE environments](#)

## SAP ASE support matrix

### Supported operating systems and database versions for SAP ASE

#### Source and Target OS and DBMS Compatibility

The source and target must be running the same Operating System combination. The Operating System platform must be the same between the source and target, even when the operating system version may differ. For example, if the source is running Red Hat Enterprise Linux 6.2 x86\_64 then the target could be running Red Hat Enterprise Linux 6.4 x86\_64, but not Solaris 10 SPARC.

The source and target can be running the same DBMS version or the target ASE instance can have a higher DBMS version, (although users can run different patch/sp levels) in order to successfully provision a VDB to the target. For example, if the source is running SAP ASE 15.7 SP140, the target can be running ASE 15.7 SP138 or ASE 16.0 SP03.

If the target is used as a staging server, the source and target must be running the same DBMS combination, although users can run different patch/sp levels (prior to Delphix 5.2.5.0, the staging server had to match the source server's version down to the SP level). For example, if the source is running SAP ASE 16.0 SP03 PL03, the target can be running ASE 16.0 SP03 PL06. However, for ASE 15.7 the versions of the source and target should both be in the 15.7 SP100 to 15.7 SP140 or 15.7 ESD#1 to 15.7 SP64 ranges. There can be no mixing of versions between these two ranges.

Delphix 5.2.5.0 and higher relaxes Delphix's version checking of the staging instance. ASE itself may or may not allow the **MOUNT** command to work between versions. Be sure to check that the **UNMOUNT** and **MOUNT** commands work between your desired ASE versions.

So for example, if we upgrade the ASE staging instance to ASE 15.7 SP140 but we keep the ASE instance hosting the VDBs at ASE 15.7 SP135, we would want to make sure that we can **UNMOUNT** a database from ASE 15.7 SP140 and then **MOUNT** it on ASE 15.7 SP135:

```
isql -Usa -Psybase -SASE157SP140
```

```
1> UNMOUNT DATABASE testdb to "/tmp/manifest"
```

```
2> GO
```

```
isql -Usa -Psybase -S ASE157SP135
```

```
1> MOUNT DATABASE testdb from "/tmp/manifest"
```

```
2> go
```

```
Msg 14580, Level 16, State 1:
```

```
Server 'ASE157SP135', Line 1:
```

```
You cannot mount the database(s) because at least one database contains  
functionality that is available only on the server on which it  
originated.
```

In the above example, ASE would not allow the database "testdb" to be mounted on the older release of ASE.

- Delphix Support Policies specifically list Major and Minor release coverage. If a minor release is listed as covered, then all patch releases under that minor release are certified.
- 64-bit OS support only

#### Key:

Color	Supported?
Y	Yes
N	No
NA	Not Applicable

Red Hat Enterprise Linux (RHEL)

Support for RHEL 8.x requires installing the `libncurses.5` library onto the host. Please reference [KBA 5622](#) for actionable steps.

## Requirements for SAP ASE environments and databases

In order to begin using SAP ASE environments with Delphix, you will need to configure the source and target hosts with the requirements described on this page.

### SAP ASE host requirements

**i** When working with ASE dSources, it is necessary that the Staging and Target ASE instances have an identical **Page Size** configuration to the dSource (e.g. 2KB / 4KB / 8KB). This is set during ASE instance installation.  
The Delphix Engine will prevent the use of incompatible instances.

These requirements are applicable to source, staging, and target environments. Target environments have additional requirements, which are detailed in the **Target Host Requirements** section below.

On each host with SAP ASE, there must be an operating system user (e.g. delphix\_os) configured to the required specifications for Delphix.

Host requirement	Explanation
Profile and privileges should be the same as the ASE user (e.g. Sybase) on the host.	For example, delphix_os should have the same environment variable (e.g. \$PATH), umask, and ulimit settings as the user sybase.
Delphix operating system user's primary group should be the same as SAP ASE instance's group.	To perform Sync/Validated Sync operations on the source database, Delphix reads a number of files like SAP ASE Backup server log file, ASE Dump History file, and backup files. If Delphix OS user does not have the same group as of the SAP ASE instance, these files will need "everyone" read permissions, which is less restrictive.
Delphix Engine Toolkit Directory on Source Host (e.g. /var/opt/delphix/toolkit) <ul style="list-style-type: none"> <li>• The delphix_os user must own the directory</li> <li>• The directory must have permissions 0770, for example, -rwxrwx---. However, you can also use more permissive settings.</li> <li>• The directory should have 256MB of available storage</li> </ul>	<ul style="list-style-type: none"> <li>• If you sync Delphix with a dSource by asking SAP ASE to create a new backup, the SAP ASE instance owner will need write permissions to the toolkit (or the mount point if you use the CLI to specify a directory other than the toolkit). Delphix will issue the "DUMP DATABASE" command to write to the staging database's "temp" directory which is mounted on the staging host.</li> <li>• Has write permission for the mount-point directory (by default the toolkit directory but can be a separate mount point specified in the command line interface)</li> </ul>
Backup Server Log File Permissions	<ul style="list-style-type: none"> <li>• In the case that the Delphix OS user is not in the same group as the SAP ASE instance user, you need to change permissions to SAP ASE Backup server log file from "rw-r---" to "rw-r-r--".</li> <li>• The "rw-r---" to "rw-r-r--" permissions change is also required if Dump History files are in use.</li> </ul>

Host requirement	Explanation
The Delphix Engine must be able to make an SSH connection to the source host (typically port 22).	

### SAP ASE database requirements

Delphix for SAP ASE requires a specific login to run discovery and linking activities for instances and databases. Delphix requires specific user permissions for database discovery and linking (detailed below).

 Discovery and Linking can be separated into separate users if desired.

 If you are using an ASE backup server instance shared with multiple ASE data server instances, the use of the dump history file feature is mandatory. This should be enabled on all instances and the dump history file in a location accessible by the Delphix OS user account from the Staging host.

### SAP ASE source database requirements

The discovery database user (delphix\_disc for example) must have SELECT privileges on the following tables for each SAP ASE instance on the source host:

- Sysdatabases
- Sysservers
- Syslisteners
- Sysconfigures
- Syscurconfigs

### Database linking

Permissions for linking environments can be included under the “discovery” user or can be a separate, dedicated role - e.g. delphix\_link. If separate, the “linking” user must be specified when linking each dSource (delphix\_link for example) that has SELECT privileges on the above tables.

If you will select “No new Full Backup” when linking, this user must also have privileges to take a new full database dump of the source database. For more information about linking options, see [Linking an SAP ASE Data Source](#)

 The link database user can be different for each instance and database on the source host.

### Sample Script to create delphix\_link on Linux

```
note: run as sa

sp_addlogin delphix_link, "StrongPassword"

go

sp_adduser delphix_link

go
```

```
grant select on sysdatabases to delphix_link
go
grant select on sys.servers to delphix_link
go
grant select on sys.listeners to delphix_link
go
```

### Requirements when resizing source databases

For SAP ASE on Delphix, transaction logs are helpful for maintaining a Timeflow via logsync. However, not all customers will want to maintain these logs for bandwidth purposes. The following section will help guide users on requirements to maintain timeflows when it comes to resizing databases with and without ( `trunc log on chkpt` ).

Active SAP ASE Feature on Source Host	Requirement
( <code>trunc log on chkpt</code> ) is disabled	take a transaction log dump immediately after the resize operation completes.
( <code>trunc log on chkpt</code> ) is enabled	take a full database dump immediately after the resize operation completes.

 If multiple resizing operations are performed without taking transaction log dumps between each operation it may be necessary to manually sync the source database dumps.

### Additional target host requirements

This section describes the user privileges, and environment discovery requirements, that are required for SAP ASE target hosts and databases, collectively referred to as target environments.

Target host requirement	Explanation
The operating system on the target environment must be the same as, or binary compatible with, the operating system on the source environment	

Target host requirement	Explanation
<p>As the Delphix Engine uses NFSv3 for mounting target host filesystems, the prerequisite packages to support NFSv3 client communication are required for normal operation, and the required services to support NFS client communications (including file locking) must be running This includes:</p> <ul style="list-style-type: none"> <li>• portmapper / rpcbind</li> <li>• status daemon (rpc.statd)</li> <li>• NFS lock manager (rpc.lockd/lockmgr)</li> </ul>	<p>The Delphix Engine uses NFSv3 as a defacto mounting standard for target host file systems.</p>
<p>SAP ASE Source/Target Environment Version Compatibility</p>	<ul style="list-style-type: none"> <li>• The major/minor/macro version of the target ASE instance should be the same or higher than the version of the source ASE instance. Delphix supports the ASE databases to be restored from lower to higher version or within different patch/ sp levels as long as SAP ASE supports it.</li> <li>• If the target environment is used as staging then the SAP ASE version on the target environment must be the same as the version on the source environment. However, EBF/SP version on the target environment can be different.</li> </ul>
<p>Create OS User (e.g. delphix_os)</p>	<p>There must be an operating system user, such as delphix_os, that meets the following requirements:</p>
<p>OS User must have - The \$SYBASE environment variable set for non-interactive shells (such as via the .bashrc configuration file)</p>	<p>Additional Settings for the \$SYBASE environment variable:</p> <ul style="list-style-type: none"> <li>• Set the PermitUserEnvironment configuration parameter to "yes" in the sshd_config file</li> <li>• Add the variable to the user's .ssh/environment file</li> <li>• Restart the SSH daemon</li> </ul>
<p>OS User must have appropriate access to Target Hosts/Instances</p>	<ul style="list-style-type: none"> <li>• Can login to the target host via Secure Shell (SSH)</li> <li>• Can login to ASE instances using isql with LANG=C set</li> </ul>
<p>OS User's Primary Group must be the same as ASE Instance's Primary Group</p>	<ul style="list-style-type: none"> <li>• If not, the file system permissions can be more restrictive.</li> <li>• This also is a better security practice than granting world read access to the toolkit or the backup files.</li> </ul>

Target host requirement	Explanation
<p>Permissions granted via sudo authorization of the commands:</p> <ul style="list-style-type: none"> <li>• Disable tty for the delphix_os user for mount and umount</li> <li>• Permission to run mount and umount as super-user.</li> <li>• On Solaris, permission to run pargs on Solaris</li> <li>• On AIX, permission to run the nfso command as super-user.</li> <li>• (Optional) On AIX and Linux, permission to run ps as super-user.</li> </ul>	<p>See <a href="#">Sudo Privilege Requirements for SAP ASE Environments</a> for further explanation of this requirement, and <a href="#">Sudo File Configuration Examples for SAP ASE Environments</a> for example file configurations.</p>
<p>There must be a database user, such as delphix_db, with the sa_role on each instance on the target environment</p>	
<p>The database user such as delphix_db for any staging instances must also have the sybase_ts_role</p>	
<p>There must be a directory on the target environment where you can install the Delphix Engine toolkit, for example, /var/opt/delphix/Toolkit.</p>	<ul style="list-style-type: none"> <li>• The delphix_os user must own the directory</li> <li>• The directory must have permissions 0770, for example, -rwxrwx--. However, you can also use more permissive settings.</li> <li>• The directory should have 1GB of available storage</li> <li>• Avoid using the home directory of the delphix_os user</li> <li>• If you intend to use the LogSync feature, it is recommended to make the toolkit directory as short as possible to keep the full path to the transaction log file names under ASE's 127 character limit. For example, create the toolkit directory as /tk. Alternatively, link the dSource using the command line interface and specify the "<a href="#">mountBase</a>" parameter to mount the staging database's devices under a directory following your own naming convention.</li> </ul>

Target host requirement	Explanation
<p>(Optional - If the target host will be used as a staging target environment)</p> <p>Must have at least one of the following two options configured:</p> <ul style="list-style-type: none"> <li>• use sp_addserver to add the staging ASE instance's Backup Server to syservers on the source ASE instance (so that remote database dump/load works)</li> </ul> <p>OR</p> <ul style="list-style-type: none"> <li>• Full and transaction dump files from the source database must be available locally to the staging database (over NFS, replication, scp, etc.)</li> </ul>	<p>(see <a href="#">Managing SAP ASE Environments</a>)</p>

Special considerations - OS user settings (If target host is hosting staging DBs)

Target host requirement	Explanation
<p>If you don't add the Delphix operating system user to the SAP ASE instance owner's group, greater permissions will need to be granted to the backup files to ensure read access to the dumps and/or transaction logs.</p>	<p>Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment).</p>
<p>ASE Instance Owner Write Permissions to the toolkit (or mount point if you use the CLI to specify a directory other than the toolkit)</p>	<p>If you sync Delphix with a dSource by asking ASE to create a new backup, the SAP ASE instance owner will need write permission to the toolkit (or the mount point if you use the CLI to specify a directory other than the toolkit). Delphix will issue the "DUMP DATABASE" command to write to the staging database's "temp" directory which is mounted on the staging host.</p>
<p>Has write permission for the mount-point directory</p>	<p>The mount-point directory defaults to the toolkit directory, which has write permissions. However, the mount-point directory can be customized, it only needs to have write permissions.</p>

Additional ASE tuning recommendations

- In SAP ASE 15.7 SP60 and higher, there is a configuration parameter named "enable large pool for load". SAP ASE automatically tunes the caches for recovery on reboot but does not do this for load database and load transaction recovery, since it could impact other databases on a production server. Delphix recommends that the staging SAP ASE instance be separate from the SAP ASE production instance and SAP ASE instances hosting VDBs so enabling this parameter should have *a beneficial impact on performance for the SAP ASE staging instance.*

- Specify the "relaxed" strategy for replacing the cache in the default data cache (sp\_cacheconfig 'default data cache', relaxed) in the SAP ASE staging instance. Since the mount/unmount process invalidates the pages anyway, the page chain is really just unneeded overhead on the staging server.
- Staging and target SAP ASE instances should have disk mirroring disabled.  
sp\_configure "disable disk mirroring" – run value should be 1, which is the default. If it is 0, change it using sp\_configure "disable disk mirroring", 1 – this parameter is static so the ASE instance must be restarted for this change to take effect.
- Delphix will mirror the number of devices used on the source database for the staging database (dSource) and each VDB created from that source database. The number of devices parameter should be scaled appropriately based on the max number of virtual databases that will be provisioned to the SAP ASE instance. This parameter can be changed using: sp\_configure "number of devices", .  
SAP ASE 15.7.0 SP100 and later releases support the shrink command. In some cases, Delphix must increase the number of devices used for databases if this command is used. Delphix creates a minimum of the same number of devices as the source database for the staging database (dSource) and each VDB and will add more devices for every 4TB of fragment holes. See SAP ASE issue [CR#799273](#) for additional details.

To support multiple VDBs and the staging databases, you may need to increase the parameter number of alarms.

 Delphix uses SAP ASE operations that use alarm structures such as MOUNT and UNMOUNT. The number of alarms limits the number of these operations which can be run concurrently. Various SAP ASE instance failures can occur if the available alarm structures are exhausted. The amount of memory consumed by increasing the number of alarm structures is small. Delphix recommends that the number of alarms value is increased to at least 4096.

#### ASE manual discovery

When an SAP ASE environment is added Delphix automatically discovers your SAP ASE instances. Manual discovery allows users to add instances that were not automatically discovered. This feature is currently only supported via the CLI. For more information please refer to [Configuring ASE Manual Discovery](#)

## Network and connectivity requirements for SAP ASE environments

### General outbound from the Delphix engine port allocation

Protocol	Port numbers	Use
TCP	25	Connection to a local SMTP server for sending email
TCP/UDP	53	Connections to local DNS servers
UDP	123	Connection to an NTP server
UDP	162	Sending SNMP TRAP messages to an SNMP Manager
TCP	443	HTTPS connections from the Delphix Engine to the Delphix Support upload server
TCP/UDP	636	Secure connections to an LDAP server
TCP	8415	Connections to a Delphix replication target. See <a href="#">Configuring Replication</a>
TCP	50001	Connections to source and target environments for network performance tests.

### General inbound to the Delphix engine port allocation

Protocol	Port number	Use
TCP	22	SSH connections to the Delphix Engine
TCP	80	HTTP connections to the Delphix GUI
UDP	161	Messages from an SNMP Manager to the Delphix Engine
TCP	443	HTTPS connections to the Delphix Management Application
TCP	8415	Delphix Session Protocol connections from all DSP-based network services including Replication, SnapSync for Oracle, V2P, and the Delphix Connector.

Protocol	Port number	Use
TCP	50001	Connections from source and target environments for network performance tests via the Delphix CLI.

#### Firewalls and intrusion detection systems (IDS)

Production databases on source environments (for dSources) are often separated from the non-production environment by firewalls. Firewalls can add milliseconds to the latency between servers. Accordingly, for best performance, there should be no firewalls between the Delphix Engine and the virtual database (VDB) target environments. If the Delphix Engine is separated from a source environment by a firewall, the firewall must be configured to permit network connections between the Delphix Engine and the source environments for the application protocols (ports) listed above.

Intrusion detection systems (IDSs) should also be made permissive to the Delphix Engine deployment. IDSs should be made aware of the anticipated high volumes of data transfer between dSources and the Delphix Engine.

#### Connection requirements for SAP ASE environments

- The Delphix Engine uses an **SSH** connection to each source environment and **SAP ASE client** connections to the SAP ASE instances on the source environment.
- The Delphix Engine uses an **SSH** connection to each target environment, **NFS** connections from each target environment to the Delphix Engine, and **SAP ASE JDBC** connections to the virtual databases on the target environment.

#### Port allocation for SAP ASE environments

The following diagram describes the port allocations for SAP ASE environments. It illustrates the ports that we recommend to be open from Delphix to remote services, to the Delphix Engine, and to the Target Environments.

Refer to [Managing SAP ASE Environments](#) for information on SAP ASE environments. The Delphix Engine makes use of the following network ports for SAP ASE dSources and VDBs:

Outbound from the Delphix engine port allocation

Protocol	Port numbers	Use
TCP	Configuration dependent	JDBC Connections to the SAP ASE instances on the source environments

Inbound to the Delphix engine port allocation

Protocol	Port number	Use
UDP	33434-33464	Traceroute from source and target database servers to the Delphix Engine (optional)
TCP/UDP	111	Remote Procedure Call (RPC) port mapper used for NFSv3 mounts

Protocol	Port number	Use
TCP	2049	NFS client from target hosts to the Delphix Engine (NFSv3 and NFSv4)
TCP	1110	Network Status Monitor (NSM) client from target hosts to Delphix Engine
TCP	54043	Client mount daemon (NFSv3 only)
TCP	54044	Lock state notification service (NFSv3 only)
TCP	54045	Network Lock Manager (NLM) client from target hosts to Delphix Engine (NFSv3 only)

Port allocation between source and staging target environments

Protocol	Port numbers	Use
TCP	Configuration dependent	SAP ASE Remote Backup Server protocol. Applies if linking using the <b>New Full Backup</b> option, or if linking with the <b>Remote Backup Server</b> option.

Port allocation between staging target environments and shared backup fileserver

Protocol	Port numbers	Use
TCP/UDP	NFS and related port numbers: <ul style="list-style-type: none"> <li>• Portmap (111)</li> <li>• NFS (2049)</li> <li>• Network Lock Manager (NLM)</li> <li>• Network Status Monitor (NSM)</li> </ul>	NFS mount point exported by an NFS shared backup fileserver. Applies if linking using the <b>Local Backup Server</b> option.

AppData port requirements

The use of AppData requires the following ports/protocols. Two important notes about these specifications:

1. The next release of the Delphix Engine will significantly augment the port/protocol utilization of AppData. The upcoming-only requirements have been marked with a \*.
2. AppData V2P uses RSYNC to export to the target. RSYNC between the target and Delphix Engine is not required for general virtualization usage. The V2P-only requirements have been marked with a ^.

<b>From Source to Delphix Engine</b>	<b>From Delphix Engine to Source</b>	<b>From Target to Delphix Engine</b>	<b>From Delphix Engine to Target</b>
RSYNC (TCP Port 873)	RSYNC (TCP Port 873)	DSP (Default TCP Port 8415)	DSP (Default TCP Port 8415)
DSP (Default TCP Port 8415)	SSH (TCP Port 22)	NFS	SSH (TCP Port 22)
*NFS	DSP (Default TCP Port 8415)	^RSYNC (TCP Port 873)	^RSYNC (TCP Port 873)

## Sudo privilege requirements for SAP ASE environments

This topic describes the rationale behind specific `sudo` privilege requirements for virtualizing SAP ASE Databases.

Privilege	Sources	Targets	Rationale
<code>pargs</code>	<b>Required on Solaris</b>	<b>Required on Solaris</b>	Delphix attempts to call <code>pargs</code> to discover the arguments of the ASE processes. It needs the name of each running dataserver or backupserver process so that it can try to connect to the instances to gather further information during the discovery process.
<code>ps</code>	Optional on Linux, AIX	Optional on Linux, AIX	<p>Delphix attempts to call <code>ps</code> to discover the arguments of the ASE processes. It needs the name of each running dataserver or backupserver process so that it can try to connect to the instances to gather further information during the discovery process.</p> <p>Unlike Solaris, Delphix can usually determine the arguments without sudo privileges on Linux/AIX. But Delphix will attempt "<code>sudo ps</code>" before attempting a regular <code>ps</code> command, and this could cause locking of the <b>delphix_os</b> account. To avoid locking issues, you can grant <code>sudo ps</code> to <b>delphix_os</b>.</p>
<code>mount/umount</code>	Not Required	<b>Required</b>	Delphix dynamically mounts and unmounts directories under the provisioning directory during VDB operations. This privilege is required because <code>mount</code> and <code>umount</code> are typically reserved for superuser.
<code>nfso</code>	Not Required	<b>Required on AIX</b>	Delphix monitors NFS read and write sizes on an AIX target host. It uses the <code>nfso</code> command to query the sizes in order to optimize NFS performance for VDBs running on the target host. Only a superuser can issue the <code>nfso</code> command.

 Default Mount Directory

By default, Delphix mounts the NFS directories for VDBs and staging databases under the toolkit directory. Sudo permissions should be granted to allow the mount/umount commands to execute under these directories unless the dSource is linked using the command-line interface (CLI) and a different NFS mount base is specified. Please refer to the Reference manual for more information on linking the dSource using the CLI and specifying the "mountBase" parameter.

**Specify the NOPASSWD qualifier**

It is required to specify the NOPASSWD qualifier within the "sudo" configuration file, as shown here: [Sudo File Configuration Examples for SAP ASE Environments](#). This ensures that the "sudo" command does not demand the entry of a password, even for the "display permissions" (i.e. "sudo -l") command.

Delphix issues "sudo -l" in some scripts to detect if the operating system user has the correct sudo privileges. If it is unable to execute this command, some actions may fail and Delphix will raise an alert suggesting it does not have the correct sudo permissions. Restricting the execution of "sudo -l" by setting "listpw=always" in the "/etc/sudoers" file when the Delphix operating system user is configured to use public key authentication will cause the Delphix operating system user to be prompted for a password which will fail certain Delphix actions. Use a less restrictive setting for listpw than "always" when the Delphix operating system user is using public-key authentication.

**SAP ASE and appData mount options**

AIX	<pre>-o cio,rw,fg,hard,rsize=\$nfs_rsize,wsize=\$nfs_wsize,nointr,timeo=600, proto=tcp,noacl</pre>
HPUX	<pre>-o rw,hard,rsize=1048576,wsize=1048576,nointr,timeo=600,proto=tcp,sui d</pre>
Solaris	<pre>-F nfs -o rw,fg,hard,rsize=1048576,wsize=1048576,nointr,timeo=600,pro to=tcp,suid,sec=sys</pre>
<p>For these platforms, depending on the NFS version used, additional options vers=3 or vers=4.x is added (x varies depending on what that platform supports. e.g. vers=4 or vers=4.1)</p>	
Linux (NFSv3)	<pre>-t nfs -o rw,fg,hard,rsize=1048576,wsize=1048576,nointr,timeo=600,tcp ,noacl,vers=3</pre>

SAP ASE and appData mount options	
Linux (NFSv4)	<pre>-t nfs4 -o rw,fg,hard,rsize=1048576,wsize=1048576,nointr,timeo=600,sec=sys,tcp,noacl</pre>
(For some flavors of Linux and NFSv4.1, additional optional 'v4.1' is added)	

- 1. AppData plugins and toolkits have some additional mount options depending on the type of toolkit/plugin.
- 2. "port=2049" is added for all the platforms.

<b>SAP ASE and zppData unmount options</b>	"-f" in most cases. Certain cases, SAP ASE uses "-lf". (Lazy unmount option)
--------------------------------------------	------------------------------------------------------------------------------

■ **Mount and unmount options subject to change**

Please note that the mount and unmount options listed above are subject to change. For example, if Delphix finds that a certain option improves performance, Delphix may add, remove or change options at anytime. Therefore, it is highly recommended to create the sudo profiles using wildcards that allow any number of options.

## Sudo file configuration examples for SAP ASE environments

This topic provides sample `sudo` file privilege configurations for using the Delphix Engine with various operating systems and SAP ASE.

### Configuring `sudo` access on Solaris for SAP ASE source and target environments

Sudo access to `pargs` on the Solaris operating system is required to discover the arguments of the ASE processes both source and target environments.

Example: Solaris `/etc/sudoers` entries for a Delphix Source for SAP ASE

```
Defaults:delphix_os !requiretty
delphix_os ALL=NOPASSWD:/usr/bin/pargs
```

On a Solaris target, `sudo` access to `mount` and `umount` is also required.

Example: Solaris `/etc/sudoers` entries for a Delphix Target for SAP ASE

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults      listpw=all
User_Alias   DELPHIX_USER=delphix_os
Cmdn_Alias   DELPHIX_CMDS= \
/usr/sbin/mount, \
/usr/sbin/umount, \
/usr/bin/pargs
DELPHIX_USER ALL=(ALL) NOPASSWD: DELPHIX_CMDS
```

### Configuring `sudo` access on Linux for SAP ASE source and target environments

On a Linux target, sudo access to `mount` and `umount` is required.

Example: Linux `/etc/sudoers` file for a Delphix Target for SAP ASE

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults      listpw=all

Defaults:delphix_os !requiretty
delphix_os ALL=NOPASSWD: \
/bin/mount, /bin/umount
```

## Configuring `sudo` access on AIX for SAP ASE source and target environments

In addition to `sudo` access to the `mount` and `umount` commands on AIX target hosts, Delphix also requires `sudo` access to `nfso`. This is required on target hosts for the Delphix Engine to monitor the NFS read write sizes configured on the AIX system. Super-user access level is needed to run the `nfso` command.

Example: AIX `/etc/sudoers` File for a Delphix Target

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults listpw=all
Defaults:delphix_os !requiretty
delphix_os ALL=NOPASSWD: \
/bin/mount, \
/bin/umount, \
/usr/sbin/nfso
```

## Examples of limiting `sudo` access for the Delphix OS user

In situations where security requirements prohibit giving the Delphix user root privileges to mount, unmount, make a directory, and remove directory on the global level, it is possible to configure the `sudoers` file to provide these privileges only on specific mount points or from specific Delphix Engines, as shown in these two examples.

**i** The Delphix Engine tests its ability to run the `mount` command using `sudo` on the target environment by issuing the `sudo mount` command with no arguments. Many of the examples shown in this topic do not allow that. This causes a warning during environment discovery and monitoring but otherwise does not cause a problem. If your VDB operations succeed, it is safe to ignore this warning. Similarly, the `ps` or `pargs` the command is used for target environment operations such as initial discovery and refresh. Some organizations configure the security on the target environments to monitor `sudo` failures and lockout the offending account after some threshold. In those situations, the failure of the `sudo` commands might cause the `delphix_os` account to become locked. One workaround for this situation is to increase the threshold for locking out the user account. Another option is to modify `/etc/sudoers` to permit the `delphix_os` user to run `ps` (`pargs`), `mkdir`, `rmdir`, and `mount` command without parameters.

**⚠** Note that the following examples are for illustrative purposes and the `sudo` file configuration options are subject to change.

### Example 1

This example restricts the `delphix_os` user's use of `sudo` privileges to the directory `/sybase`.

Note that wildcards are allowed for the options on `mount` and `umount` because those commands expect a fixed number of arguments after the options. The option wildcard on the `mount` command also makes it possible to specify the file-system being mounted from the Delphix Engine.

However, wildcards are not acceptable on `mkdir` and `rmdir` because they can have any number of arguments after the options. For those commands, you must specify the exact options ( `-p` , `-p -m 755` ) used by the Delphix Engine.

Example `/etc/sudoers` File Configuration on the Target Environment for `sudo` Privileges on the VDB Mount Directory Only (Linux OS)

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults      listpw=all

Defaults:delphix_os !requiretty
delphix_os ALL=(root) NOPASSWD: \
/bin/mount *          /sybase/*, \
/bin/mount "", \
/bin/umount *        /sybase/*, \
/bin/umount          /sybase/*, \
/bin/mkdir -p        /sybase/*, \
/bin/mkdir -p -m 755 /sybase/*, \
/bin/mkdir           /sybase/*, \
/bin/rmdir           /sybase/*, \
/bin/ps
```

Example `/etc/sudoers` File Configuration on the Source Environment to grant Super-User privileges when running PS

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults      listpw=all

Defaults:delphix_os !requiretty
delphix_os ALL=(root) NOPASSWD: /bin/ps
```

## Example 2

This example restricts the `delphix_os` user's use of `sudo` privileges to the directory `/sybase`, restricts the mount commands to a specific Delphix Engine hostname and IP, and restricts user-specified options for the `umount` command.

This configuration is more secure, but there is a tradeoff with deployment simplicity. This approach would require a different `sudo` configuration for targets configured for different Delphix Engine.

Configuring the `/etc/sudoers` File on the Target Environment for Privileges on the VDB Mount Directory Only, and Allows Mounting only from a Single Server (Linux OS)

```
# Delphix issues sudo -l so we need to allow it via listpw. Never set it to always
when using public key authentication
Defaults      listpw=all

Defaults:delphix_os !requiretty
```

```
delphix_os ALL=(root) NOPASSWD: \  
/bin/mount <delphix-server-name>* /sybase/*, \  
/bin/mount * <delphix-server-name>* /sybase/*, \  
/bin/mount <delphix-server-ip>* /sybase/*, \  
/bin/mount * <delphix-server-ip>* /sybase/*, \  
/bin/mount "", \  
/bin/umount /sybase/*, \  
/bin/umount * /sybase/*, \  
/bin/mkdir [*] /sybase/*, \  
/bin/mkdir /sybase/*, \  
/bin/mkdir -p /sybase/*, \  
/bin/mkdir -p -m 755 /sybase/*, \  
/bin/rmdir /sybase/*, \  
/bin/ps
```

## Managing SAP ASE environments and hosts

This section describes the attributes of SAP ASE environments such as information for the Delphix Connector and covers the following topics:

- [Managing SAP ASE environments overview](#)
- [Adding an SAP ASE environment](#)
- [Environment attributes for hosts with SAP ASE](#)
- [How to discover SAP ASE instances which use multiple network handlers](#)
- [Changing the host name or IP address of an SAP ASE environment](#)
- [Using HostChecker to validate SAP ASE source and target environments](#)
- [Enabling linking and provisioning for SAP ASE environments](#)

### Managing SAP ASE environments overview

This topic describes the high-level process for adding SAP ASE environments, linking SAP ASE databases to the Delphix Engine, and provisioning virtual databases.

Block diagram of linking architecture between SAP ASE environments and the Delphix engine

#### Environment setup

SAP ASE dSources are backed by a staging database that runs on a target host, as shown in the diagram. There is no requirement for additional local storage on this host, as the storage is mounted over NFS from the Delphix Engine. At Delphix, we refer to the creation and maintenance of this staging database on the staging host as "validated sync," because it prepares the dSource data on the Delphix Engine for provisioning VDBs later on. After the Delphix Engine creates the staging database, it continuously monitors the source database for new transaction log dumps. When it detects a new transaction log dump, it loads that dump to the staging database. The result is a TimeFlow with consistent points from which you can provision a virtual database (VDB), and a faster provisioning process because there is no need for any database recovery during provisioning.

When you later provision a VDB, you can specify any environment as a target, including the environment that contains the staging database. However, for best performance, Delphix recommends that you choose a different

target environment. The target must have an operating system that is compatible with the one running on the validated host, as described in [Requirements for SAP ASE Environments and Databases](#)

Workflow and tasks for SAP ASE environments

1. Add the desired source environments as described in [Managing SAP ASE Environments](#)
2. Add the desired target environments as described in [Managing SAP ASE Environments](#)
3. Link the source database as described in [Linking Data Sources with SAP ASE](#)
4. Provision VDBs as described in [Provisioning an SAP ASE VDB](#)

**Best Practice**

If possible, it is recommended to use separate SAP ASE instances for staging databases (dSources) and VDBs on target environments. This allows better control on target environments based on the resources required for SAP ASE full/transaction log dump ingestion vs VDB performance.

## Adding an SAP ASE environment

### Prerequisites

See [Requirements for SAP ASE Environments and Databases](#)

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. From the **Actions (...)** menu select **Add Environment**.
5. In the **Host and Server** tab window, select **Unix/Linux**.
6. Select **Standalone Host**.
7. Click **Next**.
8. Enter a **Name** for the environment.
9. Enter the **Host IP** address.
10. For NFS Addresses (Optional): Enter one or more comma-separated **IP Address/Hostname**  
**Note: If specified, Delphix Engine only allows NFS requests (mount, etc) originated from IP Addresses specified for the host.**
11. Enter the **SSH** port. The default value is **22**.
12. Select a **Login Type**. — Username and Password - enter the OS username and password — Username and Public Key - enter the OS username. — Password Vault - select from an existing Enterprise Password Vault

#### **Note:**

#### Using Public Key Authentication

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

- a. Select **Public Key** for the **Login Type**.
- b. Click **View Public Key**.
- c. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - i. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - ii. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - iii. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See Option 2 in [this CLI Cookbook article for instructions](#).

13. For **Password Login**, click **Verify Credentials** to test the username and password.
14. Enter a **Toolkit Path**. The toolkit directory stores scripts used for Delphix Engine operations. It must have a persistent working directory rather than a temporary one. The toolkit directory will have a separate subdirectory for each database instance. The toolkit path must have 0770 permissions.
15. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
16. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
17. Click the **Discover SAP ASE** checkbox.
18. Click **Next**.
19. In the Summary, tab confirm your selections.
20. Click **Submit**.

### Post-requisites

After you create the environment, you can view information about it by selecting **Manage > Environments** and then selecting the **environment name**.

### Configuring a non-default dump history file

Delphix, by default, uses the Dump History file that is configured for the source ASE instance. Delphix will query the source ASE instance to find this file name and use this file to find dump history. However, users can specify any other file on the source host to be used for querying the backup history. In that case, Delphix will not use the file configured for the source ASE instance but will use the file specified to get backup information. To specify a custom Dump History file, go to the **source environment > Databases**. Click the pencil button in front of **Installation Details** for the desired instance. Enter the fully qualified name of the Dump History file to be used in the text box next to **Dump History File**.

Delphix does not support rolled over Dump History Files.

## Environment attributes for hosts with SAP ASE

This topic describes the attributes of SAP ASE environments. Below you will see a section for common environment attributes shared by all types of environments as well as SAP ASE specific ones.

### Procedure

1. From your Delphix Engine, click **Manage**.
2. Select **Environments**.
3. In the **Environments** panel, click the name of an environment to view its attributes.
4. Next to **Attributes**, click the Pencil icon to edit an attribute.

### Common environment attributes

Attribute	Description
Environment Users	The users for that environment. These are the users who have permission to ssh into an environment or access the environment through the Delphix Connector. For more information on the environment user requirements, see the Requirements topics for specific data platforms.
Host Address	The IP address of the environment host.
DSP KeyStore Path	The path to the user-managed DSP Keystore.
DSP KeyStore Alias	The lowercase alias to use inside the user-managed DSP Keystore.
DSP KeyStore Password	The password for the user-managed DSP Keystore.
DSP TrustStore Path	The path to the user managed DSP truststore.
DSP TrustStore Password	The password for the user managed DSP truststore.
OS	The name of the host operating system.
Version	The version of the host operating system.
Release	The release of the host operating system.
Time Zone	The timezone of the host operating system.
Total RAM	The amount of RAM on the host machine.

Attribute	Description
Processor Type	The processor type of the host machine.
Traceroute	Traceroute info from target host to Delphix Engine.
Notes	Any other information you want to add about the environment.
Java Development Kit	The currently selected JDK kit will be shown.
Java Development Kit (JDK) Path	Location of the Java Development Kit (JDK) used for the host. Only specified if the feature to provide your own JDK is enabled, otherwise, the defaults are used per our <a href="#">Java Support Matrix</a>

## SAP ASE environment attributes

Attribute	Description
Database User	User for Delphix to use for SAP ASE database operations.
DB Password	Credentials to use for the database user in this environment.

## How to discover SAP ASE instances which use multiple network handlers

When adding a SAP ASE or Sybase ASE environment, the Delphix Engine may not be able to discover ASE instances that are not listening on the same network address that the engine used for discovery. In these cases, you may receive the following warning:

```
WARNING: Error during discovery for instance "INSTANCENAME" : "Failed to
connect to instance "INSTANCENAME over JDBC.". Skipping discovery for
instance "INSTANCENAME".
```

### Troubleshooting

An ASE instance may have been configured to listen on other network interfaces for one of the following reasons:

- To support the use of clustering/failover technologies such as Veritas Cluster Server
- To support the concept of "virtual hostnames" or "virtual IPs" (VIPs) to provide abstraction for client applications
- To facilitate a previous database migration to new infrastructure
- Database administrators configured it manually for other reasons

For guidance and best practices for configuring the Delphix Engine to work with clustering or failover technologies, contact your Professional Services or Customer Success representative.

To verify whether an ASE instance is using multiple network interfaces, use the `sp_listener` stored procedure when connected to the instance using `isql` :

```
1> sp_listener status 2> go      proto host port status
-----
secondary-hostname-or-ip-address 4559 active      tcp
```

As described in the ASE document [Configuring the Server for Multiple Network Handlers](#), this configuration is read from the `$SYBASE/interfaces` file on your ASE server during instance startup.

### Resolution

To allow discovery of instances using multiple network interfaces, use the **Add Environment** dialog to add the environment ONCE per network interface.

Each environment added in this way should have both of the following:

- A unique Host Address; and
- A unique Toolkit Path

The Delphix Engine expects that the files deployed to the Delphix Toolkit directory are persistent. Any failover of the ASE service to a different host must ensure that the Delphix Toolkit directory remains consistent between both hosts, with all files and permissions intact.

Deploying the Delphix Toolkit multiple times will result in increased disk space consumption. It may circumvent concurrency limitations that the Delphix Engine introduces to minimize its impact on your source environments. If your environment requires you to add the same host several times using this process, contact your Delphix

Professional Services representative or Customer Success Manager to discuss best practices or alternative solutions.

Using the example interfaces file provided above, you could use the following inputs to add the `INSTANCENAME` instance:

## Add Environment

- Host and Server
- Environment Settings
- Summary

**DSP TrustStore Password ⓘ**

**Login Type**

Username and Password

Username and Public Key

**OS Username**

**OS Password**

**Toolkit Path**

**Discover SAP ASE**

Enabled

**ASE DB Username**

**ASE DB Password**

**Notes**

## Changing the host name or IP address of an SAP ASE environment

This topic describes how to change the hostname or IP address for source and target environments, and for the Delphix Engine.

### Procedure

#### For source environments

1. Disable the dSource as described in [Enabling and Disabling SAP ASE dSources](#)
2. If the **Host Address** field contains an IP address, edit the IP address.
3. If the **Host Address** field contains a hostname, update your Domain Name Server to associate the new IP address to the hostname. The Delphix Engine will automatically detect the change within a few minutes.
4. In the **Environments** screen of the Delphix Engine, refresh the host.
5. Enable the dSource.

#### For VDB target environments

1. Disable the VDB as described in [Enabling and Disabling SAP ASE dSources](#)
2. If the **Host Address** field contains an IP address, edit the IP address.
3. If the **Host Address** field contains a hostname, update your Domain Name Server to associate the new IP address to the hostname. The Delphix Engine will automatically detect the change within a few minutes.
4. In the **Environments** screen of the Delphix Engine, refresh the host.
5. Enable the VDB.

#### For the Delphix engine

1. To stop running your VDB select the red **Stop** button located on the VDB **Configuration** tab.
2. Disable all dSources as described in [Enabling and Disabling SAP ASE dSources](#)
3. You can use either the command-line interface or the Delphix Setup application to change the IP address of the Delphix Engine.
  - a. To use the command-line interface, press **F2** and follow the instructions described in [Setting Up Network Access to the Delphix Engine](#)
  - b. To use the Delphix Setup application, go to **Delphix Management > Engine Setup** in the Delphix Management application, or click **Server Setup** in the Delphix Engine login screen.
    - i. In the **Network** panel, click **Modify**.
    - ii. Under **DNS Services**, enter the new IP address.
    - iii. Click **OK**.
4. Refresh all Environments by clicking the **Refresh** symbol on the **Environments** screen.
5. Enable all dSources as described in [Enabling and Disabling SAP ASE dSources](#)
6. To start all VDBs, click the **Start** button located on the VDB **Configuration** tab.

## Using HostChecker to validate SAP ASE source and target environments

### What is HostChecker?

The HostChecker is a standalone program which validates that host machines are configured correctly before the Delphix Engine uses them as data sources and provision targets.

Please note that HostChecker does not communicate changes made to hosts back to the Delphix Engine. If you reconfigure a host, you must refresh the host in the Delphix Engine in order for it to detect your changes.

You can run the tests contained in the HostChecker individually, or all at once. You must run these tests on both the source and target hosts to verify their configurations. As the tests run, you will either see validation messages that the test has completed successfully, or error messages directing you to make changes to the host configuration.

### Prerequisites

- Make sure that your source and target environments meet the requirements specified in [SAP ASE Support and Requirements](#).

### Procedure

1. Download the HostChecker tarball matching the host's operating system from <https://download.delphix.com/> (for example: `hostchecker_linux_x86.tar`).
2. Create a working directory and extract the HostChecker files from the HostChecker tarball.

```
mkdir dlp-host-checker
cd dlp-host-checker/
tar -xf hostchecker_linux_x86.tar
```

3. Change to the working directory and enter this command. Note that for the target environments, you would change `source` to `target`.

```
$ cd hostchecker
$ ./hostchecker.sh
Extracting the JDK from the tarball jdk.tar.gz.
Please enter whether this machine is a source or a target:target
1: Check ASE environment
2: Check all ASE instances
3: Check all the Oracle installations
4: Check homedir permissions
5: Check Linux Performance Settings
6: Check mkdir and rmdir
7: Check the MySQL installation
8: Check network port access
9: Check the Oracle CRS home
10: Check for ssh connectivity
11: Check sshd_config for timeout configuration
12: Check user sudo privileges
13: Check toolkit path
all: Execute all checks
quit: Exits
```

Please select an option:

**Note:**

**Don't Run as Root**

**Don't run the HostChecker as root; this will cause misleading or incorrect results from many of the checks.**

4. Select which checks you want to run. We recommend you run all checks (excluding Oracle and MySQL) if you are running Hostchecker for the first time.
5. Pass in the arguments the checks ask for.
6. Read the output of the check.
7. The error or warning messages will explain any possible problems and how to address them. Resolve the issues that the HostChecker describes. Don't be surprised or undo your work if more errors appear the next time you run HostChecker, because the error you just fixed may have been masking other problems.
8. Repeat steps 3–7 until all the checks return no errors or warnings.

Tests run

Test	SAP ASE Source	SAP ASE Target	Description
<b>Check SAP ASE environment</b>	X	X	<ul style="list-style-type: none"> <li>• Checks that the <b>\$SYBASE</b> environment variable exists for interactive logs. <b>NOTE:</b> It is still necessary to check that it is defined for non-interactive logins (ssh user@host env   grep SYBASE).</li> <li>• Checks that the "<b>isql_r64</b>" binary can be found underneath the <b>\$SYBASE</b> environment variable.</li> </ul>
<b>Check All SAP ASE instances</b>		X	<p>Attempts to connect to each running SAP ASE instance via "<b>isql_r64</b>" (utilizing the \$SYBASE/interfaces file) and execute the following queries:</p> <pre>select @@servername select count(*) from master..syslisteners select count(*) from master..sys.servers select count(*) from master..sys.databases select count(*) from master..sys.usages select @@version select @@maxpagesize SELECT srvnetname FROM master..sys.servers WHERE srvname='SYB_BACKUP'</pre>
<b>Check all the Oracle installations</b>	N/A	N/A	

Test	SAP ASE Source	SAP ASE Target	Description
<b>Check homedir permissions</b>	X	X	Check that the home directory, the ~/.ssh directory, and the ~/.ssh/authorized_keys file exist, that they are owned by the user invoking this check, and that they are not 'group' or 'other' writable.
<b>Check performance=""&gt;&gt;</b>		X	Check target's kernel settings necessary to optimize performance.
<b>Check mkdir and rmdir</b>		X	Tests that the user can mkdir and rmdir under both the toolkit directory and the specified mount path.
<b>Check the MySQL installation</b>	N/A	N/A	
<b>Check network port access</b>	X	X	Can be used to test access to specified ports on the Delphix Engine. See <a href="#">Network and Connectivity Requirements for SAP ASE Environments</a> for a list of ports.
<b>Check the Oracle CRS home</b>	N/A	N/A	
<b>Check Oracle DB Instance</b>	N/A	N/A	
<b>Check for ssh connectivity</b>	X	X	Verifies that the environment is accessible via SSH
<b>Check sshd_config for timeout configuration</b>		X	Check that sshd_config does not contain ClientAliveInterval or ClientAliveCountMax entries.
<b>Check toolkit Path</b>	X	X	Verifies that the toolkit installation location has the proper ownership, proper permissions, and enough free space.

Test	SAP ASE Source	SAP ASE Target	Description
<b>Check user sudo privileges</b>	X	X	Verifies that the operating system user can execute certain commands with necessary privileges via <code>sudo</code> . This only needs to be run on target environments. See the topic <a href="#">Requirements for SAP ASE Environments and Databases</a> for more information.

## Enabling linking and provisioning for SAP ASE environments

This topic describes how to enable and disable provisioning and linking for SAP ASE databases.

Before a database can be used as a dSource, you must first make sure that you have enabled linking to it. Similarly, before you can provision a VDB to a target database, you must make sure that you have enabled provisioning to it.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **Databases** tab.
5. Click the **pencil** icon located next to the database **Installation Details**.
6. Select the **Allow Provisioning** checkbox to enable provisioning, deselect the checkbox to disable provisioning.
7. Click **show details** for the database.
8. Slide the button next to **Allow Linking** to **On** or **Off** to enable or disable linking.

## Linking data sources and Syncing Data with SAP ASE

Creating a dSource will ingest data from the source and create a dSource on the engine. The dSource is an object that the Continuous Data Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools.

This section covers the following topics:

- [Linking SAP ASE data sources: an overview](#)
- [Linking data sources with SAP ASE](#)
- [Linking data sources with encrypted SAP ASE database](#)
- [Data management settings for SAP ASE dSources](#)
- [Upgrading a SAP ASE dSource](#)
- [Detaching and re-attaching SAP ASE dSources](#)
- [Deleting an SAP ASE dSource](#)
- [Enabling and disabling SAP ASE dSources](#)
- [Working with SAP ASE snapshots](#)

## Linking SAP ASE data sources: an overview

This topic describes basic concepts behind the creation of dSources from SAP ASE databases.

### Initial linking and staging databases

A dSource is a copy of a physical database that is created when the Delphix Engine links to and loads the database from a backup. The database backup can be a new full database backup that the Delphix Engine initiates, the most recent existing database backup, or an existing database backup specified by the user. When loading from an existing backup, the backup should be in a location that the source environment user can access.

After obtaining the initial snapshot and linking the dSource, the Delphix Engine keeps the dSource and the source database in sync by monitoring the source database for new transaction log dumps and then applying those backups on a standby database. This database is called the "staging database." A target environment that hosts one or more staging databases is referred to as a "staging target."

After you have linked a database into the Delphix Engine, you can re-initialize it by performing a sync on the dSource.

 There is an SAP ASE feature that affects the size of database dumps which correspondingly affect the amount of space consumed on the storage attached to the Delphix Engine. If the SAP ASE "sp\_dumpoptimize" feature is set to maximum as follows, more disk space will be consumed on Delphix storage because SAP ASE writes both allocated and unallocated pages into the dump files:

```
sp_dumpoptimize 'archivespace = maximum'
```

### SAP ASE source and staging database compatibility

You may use different SAP ASE patch level versions between source and staging hosts. The major version of SAP ASE must still be the same. The only caveat is for SAP ASE 15.7 - where the source and staging patch levels must both be either any version below SP64 or both be any version above SP100.

## Linking data sources with SAP ASE

The dSource is an object that the Continuous Data Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools. For an overview of all dSource related actions, please visit [Managing Data Sources](#).

Continuous Data for SAP ASE databases leverages backup-based ingestion, which means that Delphix will look for, or sometimes initiate the creation of, a backup through your SAP ASE backup server. From there, the backup is restored on a staging server and the staging copy is then ingested into Delphix. See [Delphix Architecture with SAP ASE](#) for more information.

When linking a dSource from an SAP ASE source database, Delphix offers several different methods of capturing backup information:

- ASE Managed Backups, where the SAP ASE source database schedules and initiates backups. This method supports various backup types which include:
  - Full backups
  - Transaction log backups (with LogSync disabled)
  - Transaction log backups (with LogSync enabled)
- Delphix Managed Backups, where the Delphix Engine schedules and initiates the backups from the source database, and captures them.

### ASE managed backups

Further contextual information on the various backup types (listed above):

- Full Backups - A snapshot will be created on the Delphix Timeflow for each Full backup.
- Transaction log backups (with LogSync disabled) - A snapshot will be created on the Delphix Timeflow for each transaction log backup.

#### **Transaction logs**

Transaction logs are not collected if:

- a) there are gaps in the sequence of log backups (a break in the “log chain”).
- b) the available log backups do not include any changes since the last successful Delphix snapshot.

- Transaction log backups (with LogSync enabled) - A snapshot will be created on the Delphix Timeflow for each transaction log backup. In addition, point-in-time provisioning will be an available option if you would like to provision from any point in between snapshots.

#### **Log files**

Log files consume additional space on the Delphix Engine and are managed according to the defined retention policy for logs.

### Delphix managed backups

When the checkbox for Delphix Managed Backups is selected, the Delphix Engine will initiate a full backup of the source database for the initial load of the dSource. Thereafter, the Delphix Engine will initiate full backups of the source database using the schedule specified by the selected SnapSync Policy. If you select the None policy, the Delphix Engine will not automatically initiate a full backup, but you can initiate them manually using the snapshot (camera) icon.

Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment)

## Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Click the plus icon and select **Add dSource**.

**Note:**

Delphix looks for the backup files on the staging host (unless a "remote" backup server is used in which case, the remote host is used which is often the source environment).

4. In the **Add dSource** wizard, select the source environment with the correct environment-based user.
5. Enter your login credentials for the source database and click **Next**.
6. Enter a name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. Select the **Data Management** settings needed, as described in [Data Management Settings for ASE Data Sources](#).
8. From the **Data Management** tab under the **Initial Load** option, select and enter any **additional settings** needed. There are three options for the initial load of the dSource:
  - a. If the source ASE instance resides on the same server as the staging ASE instance, the staging database's NFS mounted "temp" directory will be present for the source database to write to in response to the "DUMP DATABASE" command.
  - b. If the source and staging ASE instances are configured to allow remote access to the backup servers and the dSource is linked using the Remote Server option as described below. Delphix will then issue the "DUMP DATABASE" command and append the "AT <staging\_backup\_server\_name>" clause so that the dump is written to the staging backup server.
  - c. (Recommended) **New Full Backup** - Lets Delphix create a new full backup file and load it. Note - that when Delphix creates the backup, it is moved to Delphix's NFS-mounted storage located on the stage host rather than. The backup will be located in the "temp" directory and will be deleted once the Delphix Engine has restored the backup and created a dSource from the restored staging database. This means that this option will work under two scenarios:
    - d. Most Recent **Existing Full Backup** – Find the most recent existing full backup file in the Backup Location and load it.
 

**Note:**  
If Dump History is not active on the Source Database: Choosing this option can delay completion of the dSource link as Delphix attempts to find and catalog every single backup listed in the source database's backup server log file.
    - e. Specific **Existing Full Backup** – Specify which backup files in the Backup Location you want to load. Choosing this option is much faster because Delphix will skip directly to loading the desired backup and only start to search for and catalog backups in the background after the linking of the source database has completed.
 

**Note:**  
When using a dump taken with the deprecated compression syntax, select the Specific Existing Full Backup option for Initial Load and, for each stripe, type compress::<file name> into the text box.
9. Select the Staging environment and ASE instance that will be used to manage the staging database used for validated sync of the dSource.
10. Select any policies for the new dSource.
11. Click **Next**, then specify any pre-hook and post-hook scripts.
12. Review the dSource Configuration and Data Management information, and click **Submit** to begin provisioning the VDB.

## Linking data sources with encrypted SAP ASE database

This topic describes the behavior of the Delphix Engine when linking to a dSource based on an encrypted SAP ASE database.

Beginning with version 16.0, SAP ASE supports the Database Encryption feature. You can link the encrypted source databases to a dSource by following the basic procedure described in [Linking Data Sources with SAP ASE](#) but the user needs to ensure that the same key with the same name is present on the staging instance as it was on the source instance. The keys should be imported from the source instance. Refer to the configuration steps 4 and 5 of [Delphix Implementation of Database Encryption](#) to export and import the master and encryption key.

- If a user links a database when it is unencrypted and then encrypts it, the subsequent syncs will fail.
- If a user links an encrypted database and then decrypts the source database, the subsequent syncs will fail.
- If a user changes the encryption key, the subsequent syncs will fail.

In the case of the above failures, the user will be prompted to apply a full backup with the “Drop and Recreate Devices” option enabled (for once), and subsequent snap and validate sync will run without any failures. See [Working with Snapshots](#)

### **Exceptions with suggested actions are raised in the following scenarios:**

- If there has been a change in the encryption status of a source database since it was last synced or the key has changed.
- If the required encryption key is not present on the staging instance during the linking.

## Data management settings for SAP ASE dSources

Each dSource has its own data management settings, which can be configured during the linking workflow as well as on the configuration page for that dSource. You can configure data management settings to improve overall performance and meet your requirements.

The following settings are available for SAP ASE data sources:

Setting	Explanation
Backup Path	The directory where Delphix will search for backups for data ingestion. Delphix recursively searches this location, so the database backups or transaction logs can reside in any subdirectories below the path entered.
Validated Sync Mode	<p>ASE Validated Sync is either enabled or disabled. Delphix stays in sync with source databases by monitoring the ASE backup server log or dump history file (depending on the dSource configuration). When it sees a new database dump or transaction log has been created, it attempts to load it into the ASE staging instance.</p> <ul style="list-style-type: none"> <li>• Enabled - Delphix automatically ingests either transaction logs or full database dumps depending on the source database's configuration.</li> <li>• Disabled - Delphix does not actively monitor the source database's backup server log or dump history file and does not automatically ingest backups.</li> </ul>
Dump History	Delphix Validated Sync will leverage Dump History files to locate and ingest backups. This setting is recommended to improve the data ingestion and syncing processes.
LogSync	<p>When enabled, Delphix copies the transaction logs to Delphix storage to allow precise point-in-time provisioning.</p> <p><b>Note:</b> If Dump History is not enabled, due to SAP ASE CR 800569, Delphix can only support transaction logs generated in intervals greater than one minute apart for SAP ASE versions 16.0 SP02 through SAP ASE 16.0 SP02 PL04. This ASE bug inadvertently removed the second and millisecond precision from the dump header sequence dates preventing Delphix from knowing what order to apply the transaction logs when there are multiple transaction logs dumped within the same minute.</p>
Source of Production Backup	<p>You may select a staging or remote server as the location for the Delphix Engine to ingest backups.</p> <p><b>Note</b> - Selecting a staging server is the most common application for ingesting source-based backups. One major reason for this is the ability to use Validated Sync to coordinate backup ingestion.</p>
Dump Password	SAP ASE has an optional field for database dumps (backups) to prevent unauthorized loads. If enabled, Delphix will need to store the dump password in order to restore the SAP ASE backup for ingestion. Delphix also provides the option to propagate password protection to established dSources in the case of an active password on the originating database dump or transaction log dump files. Setting this option causes Delphix to add the "WITH passwd=" clause to the "LOAD" commands.

## Procedure

1. Enter the **Backup location**. This is the directory where the database backups are stored. Delphix recursively searches this location, so the database backups or transaction logs can reside in any subdirectories below the path entered.
2. Select the **Staging environment** and ASE instance name.
3. Enable or disable Validated Sync Mode. Validated Sync Mode (also known as ValidatedSync) is a background process that looks for new full or transaction log backups either by monitoring ASE Backup Server's log file or Dump History file for a new database or transaction log dumps. When Delphix detects a new dump is available it attempts to load it into the staging ASE database.
4. Enable or disable **Use dump history**. If Dump History is enabled, Delphix uses the ASE Dump History file to find information about backups being performed on the source database and to find the next backup to be used for Validated Sync.
5. Enable or disable **LogSync**. LogSync copies the transaction logs to Delphix storage which enables provisioning VDBs from a specific point-in-time in rather than just a particular backup

**Note:**

LogSync support limitations

[If Dump History is not active on the Source Database] Due to ASE CR 800569, Delphix can only support transaction logs generated in intervals greater than one minute apart in ASE versions 16.0 SP02 through ASE 16.0 SP02 PL04. This ASE bug inadvertently removed the second and millisecond precision from the dump header sequence dates preventing Delphix from knowing what order to apply the transaction logs in when there are multiple transaction logs dumped within the same minute.

6. Select **Backup location type**.
7. Click **Advanced** to edit Source of Production Dump, External Data Directory, Retention policies, or Dump Password.

**Note:**

External Data Directory

The External Data Directory feature is not currently used with ASE dSources and is targeted for removal in a future release of Delphix.

Remote Server should be selected when database dumps cannot be found on the Staging Environment. This option can be used with any of the initial load selections (New Full Backup, Most Recent Existing Full Backup or Specific Existing Full Backup). If selected, fill out additional settings as needed:

- a. Enter the Remote Server Name. This is the name of the backup server used when the dump was created.
- b. Select the Remote Host and Remote User that the backup server is located on.
- c. As noted, the interfaces file on both the staging and remote environments must be modified to point at each other's backup servers.
- d. The Create Dump Password sets a dump password for the dSource. Select this only if the dump password option was used to create a password on the database dump or transaction log dump files. Setting this option causes Delphix to add the "WITH passwd=" clause to the "LOAD" commands.

## Upgrading a SAP ASE dSource

This topic describes how to upgrade SAP ASE dSources.

### Prerequisites

- The staging SAP ASE instance must be the same version as the SAP ASE instance hosting the upgraded source database.

### Procedure

1. Login to the **Delphix Management** application.
2. In the top menu bar, click **Manage** and select **Datasets**.
3. Select the **dSource** to be upgraded.
4. Disable the dSource.
  - a. From the **Actions (...)** menu select **Disable**.
  - b. In the Disable dialog select **Disable**.
5. Upgrade the source and staging ASE instances (Delphix requires the source and staging ASE instances to be at the same major release level).
6. Click the **Refresh** icon ( under the **Manage > Environments** menu ) to refresh the Delphix environment hosting the source and staging ASE instances so that Delphix registers the new version of ASE.
7. Enable the dSource.
  - a. From the **Actions (...)** menu select **Enable**.
  - b. In the Enable dialog select **Enable**.

### Additional steps

If Delphix was unable to discover the SAP ASE instances automatically using Manual Discovery, you will need to manually update the version by completing the following procedure, [CLI Cookbook: Configuring SAP ASE Manual Discovery](#)

## Detaching and Re-attaching SAP ASE dSources

This topic describes how to detach dSources and re-attach them to a different source database.

Each dSource contains metadata that associates it with the source database, as well as the data it has ingested from the source database in the form of snapshots up to that point. It is possible to detach, or unlink, a dSource from its source database. This breaks the association with the source database without affecting the data within the Delphix Engine. Detached dSources and their source databases have these properties:

- A detached dSources can still be used to provision a virtual database (VDB).
- You can re-link the source database as a different dSource.
- Any child VDBs that were provisioned from this dSource will only be able to be refreshed from the most recent snapshot available on the dSource.
- If you need a VDB from a newer snapshot, you would need to provision a new VDB. Once you have provisioned the new VDB you can delete the old VDBs provisioned from this dSource. You can delete the old dSource when it is no longer needed.

### Detaching a dSource

1. Login to the **Delphix Management** application as a user with **OWNER** privileges on the dSource, group, or domain.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **Dataset** you want to unlink.
5. From the **Actions** menu (...) select **Unlink dSource**. A warning message will appear.
6. Click **Unlink** to confirm. The status of the dSource will show as Detached.

### Rebuilding source databases and using VDBs

In situations where you want to rebuild a source database but retain the existing dSource, you will need to detach the original dSource and create a new one from the rebuilt data source.

1. Detach the dSource as described in the procedure on this page.
2. You cannot attach a dSource with the same name as a dSource that is already attached. If you intend to give the new dSource the same name as the original one, rename the detached dSource.
  - a. At the top of the **Configuration** tab, next to the dSource's name, click the **Edit** (pencil) icon.
  - b. After renaming the dSource, click the **checkmark**.
3. Create the new dSource from the rebuilt database.

You will now be able to provision VDBs from both the detached dSource and the newly created one, but the detached dSource will only represent the state of the source database prior to being detached.

### Attaching a previously detached dSource

The attach operation is supported via the UI. You can only re-attach databases that represent the same physical database.

#### Attaching a dsource via the UI:

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **Dataset** you want to link.
5. From the **Actions** menu (...) select **Link dSource**.
6. In the Link dSource window click **Link** to confirm.

## Link dSource ✕

## Deleting an SAP ASE dSource

This topic describes how to delete an SAP ASE dSource.

Deleting a dSource will delete the dSource metadata for a particular source database, along with all snapshots, logs, and policies stored in Delphix. This is a permanent operation, and re-attaching the dSource will require [a new linking operation](#). If a dSource is deleted, it does not affect your source database.

If you wish to temporarily disable your dSource without deleting it, you can follow the steps to [Enabling and Disabling SAP ASE dSources](#) instead.

### Prerequisites

You cannot delete a dSource that has dependent virtual databases (VDBs). Before deleting a dSource, make sure that you have deleted all dependent VDBs as described in [Deleting a VDB](#).

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Click **Datasets**.
4. In the **Datasets** list, select the **dSource** you want to delete.
5. From the **Actions** menu (...) select **Delete**.
6. Click **Delete** to confirm.

Deleting a dSource will also delete all snapshots, logs, and descendant VDB refresh policies for that dSource. You cannot undo the deletion.

## Enabling and disabling SAP ASE dSources

This topic describes how to enable and disable dSources when certain operations against the source database must occur outside of Delphix.

Some operations, such as restoring the source database from a backup, will require that the dSource be temporarily disabled. Disabling a dSource turns off communication between it and the source database, but it does not tear down the configuration that enables communication and data updating to take place. When a disabled dSource is later enabled, it will resume communication and incremental data updates from the source database according to the original policies and data management configurations that you set.

Disabling a dSource is also a prerequisite for several other operations, such as database migration and upgrading the dSource metadata after upgrade of the associated data source.

### Procedure

Disabling a dSource will stop further operations on the Delphix Engine related to the dSource.

1. Login to the Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dSource** you want to disable.
5. In the upper right-hand corner, from the **Actions** menu (...) select **Disable**.
6. In the Disable dialog select **Disable**.

When you are ready to enable the dSource again, from the Actions menu (...) select **Enable**, and the dSource will continue to function as it did previously.

## Working with SAP ASE snapshots

Taking a snapshot creates a new snapshot entry in the dSource's Timeflow.

### Snapshot

This section lists the steps to take a snapshot and delete the same.

Login to the **Delphix Management** application.

1. Click **Manage** and select **Datasets** from the dropdown list.
2. Select the dSource you want to Snapshot.
3. Click the **Camera** icon.
4. Select the method to take the snapshot. See [Quick Start Guide for SAP ASE](#) for information on Delphix Managed Backups.

You can optionally select the **Enable** checkbox under **Drop and recreate devices**. This option can be used if the previous sync failed because of device mapping issues. When the sync operation is performed with this option set to true, Delphix Engine will not try to re-map the existing devices; instead, it will delete them and create new devices on the staging database. This option should only be used if the previous sync had failed due to device remapping, as this will increase disk usage.

**Snapshot** ✕

---

Choose a method to take a snapshot.

New Full Backup

Most Recent Existing Full Backup

Specific Existing Full Backups

**Drop and recreate devices** ⓘ

Enable

---

Cancel Snapshot

5. From the Snapshot dialog, click **Snapshot**.
6. Under the **Timeflow** tab, choose an option to view the snapshot and verify the snapshot you just created.
7. To delete, select a snapshot you want to delete, and from the Actions menu (...) select **Delete Snapshot**.
8. Under the **Timeflow** tab, choose an option to view the snapshot and verify the snapshot you just deleted.

## Provisioning and managing VDBs from SAP ASE

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment.

From a dSource, you can select a snapshot or point in time to create a VDB. SQL Server VDBs each have their own configuration settings as described in Configuration Settings for ASE Virtual Databases below.

This section covers the following topics:

- [Overview of provisioning SAP ASE virtual databases](#)
- [Provisioning an SAP ASE VDB](#)
- [Provisioning a VDB from an encrypted SAP ASE database](#)
- [Provisioning an SAP ASE VDB from a replicated VDB or dSource](#)
- [Resizing an SAP ASE VDB](#)
- [V2P with an SAP ASE dSource or VDB](#)
- [Additional SAP ASE VDB topics](#)

## Overview of provisioning SAP ASE virtual databases

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment, as described in the overview for [Managing Environments and Hosts](#) and [Requirements for SAP ASE Environments and Databases](#).

From a dSource, you can select a snapshot or point in time to create a VDB. SQL Server VDBs each have their own configuration settings as described in Configuration Settings for ASE Virtual Databases below.

### Procedure

1. In the Datasets panel on the left-hand side, click the group containing the dSource or VDB from which you want to provision.
2. Click the **Timeflow** tab.
3. Select a snapshot or open LogSync timeline to provision by a specific log or point in time.
  - Find more detail about initial provisioning options in the section ‘Provisioning by Snapshot or LogSync’ below.
4. Click to open the Provision VDB wizard, and select a compatible Target Environment for the new ASE VDB
5. Review the information presented for Target Configuration and edit as necessary.
6. Select a Snapshot Policy for the VDB.
7. (Optional) - Selective Data Distribution - After policies, there is a masking option.
8. Enter any operations that should be run in the Hooks page. These scripts can be managed after provision in the VDB’s configuration page.

When provisioning starts, you can review the progress of the job by selecting the VDB and clicking on the Status tab, or by selecting Manage/Dashboards and viewing the Job History panel. Alternatively, you could see this in the Actions Sidebar. When provisioning is complete, the VDB will be included in the group you designated and listed in the Datasets panel. If you select the VDB in the Datasets panel and click the Configuration tab, you can view information about the database and its Data Management settings.

### Provisioning by snapshot or LogSync

When provisioning by Snapshot, you can provision to the start of any particular snapshot by time.

Provisioning by snapshot/time	Description
Provisioning By Snapshot	You can provision by using a Snapshot. In that case, a new VDB will be provisioned to the database state as of the Snapshot.
Provision by Time	If you have enabled Log Sync, you can provision a new database to a point in time. You can select a snapshot and then using time entry fields, specify a Point in Time. Delphix will use the selected snapshot to restore the VDB and use the log files to roll forward the VDB to the selected time.

### Configuration settings for ASE virtual databases

Each VDB has its own data management settings, found during the provisioning workflow as well as in the configuration page for that VDB. When you create a SAP ASE VDB, Delphix copies most configuration settings from the dSource and uses them to create the VDB. However, you can customize these with the following settings:

Setting	Explanation
Recovery model	The current recovery model of the source database. This field will auto-populate with information from the dSource.
Auto VDB restart	Enabling this option will automatically restart this VDB whenever its target host is rebooted.

#### Automatic VDB restart on target server after reboot

The Delphix platform now automatically detects whether a target server has been rebooted, and proactively restarts any VDB on that server that was previously up and running. This is independent of the data platform. It is done as if you realized a target server was restarted and issued a start command from the Delphix platform. This feature is compatible with Self-Service ordering dependencies and is limited to non-clustered VDBs.

To enable automatic restart, complete the following steps:

- When provisioning a new VDB in the VDB Provisioning wizard, check the **Auto VDB restart** box.

Once the VDB has been provisioned, you will be able to turn **Automatic VDB restart** on.

1. In the **Datasets** panel, select the VDB.
2. Select the **Configuration** tab.
3. Select **Source** sub-tab.
4. Select **Database edit**.

## Provisioning an SAP ASE VDB

This topic describes how to provision a virtual database (VDB) from an SAP ASE dSource.

### Prerequisites

- You must have already linked a dSource from a source database, as described in [Linking Data Sources with SAP ASE](#), or have already created a VDB from which you want to provision another VDB.
- You must have already set up target environments as described in [Adding an SAP ASE Environment](#).
- Ensure that you have the required privileges on the target environment, as described in [Requirements for ASE Environments and Databases](#).
- If you are provisioning to a target environment that is different from the one in which you set up the staging database, you must make sure that the two environments have compatible operating systems, as described in [Requirements for SAP ASE Target Hosts and Databases](#). For more information on the staging database and the validated sync process, see [Managing SAP ASE Environments Overview](#).

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**
3. Select **Datasets**.
4. Select a **dSource**.
5. Select a **means of provisioning**.
6. Click **Provision**. The **Provision VDB** panel will open, and the **Instance** and **Database Name** fields will auto-populate with information from the dSource.
7. Select whether to enable **Truncate Log on Checkpoint** database option for the VDB.
8. Click **Next**.
9. Select a **Target Group** for the VDB. Click the green **Plus** icon to add a new group, if necessary.
10. Select a **Snapshot Policy** for the VDB. Click the green **Plus** icon to create a new policy, if necessary.
11. Click Auto VDB Restart to enable VDBs to be automatically restarted when staging/target host gets rebooted, if necessary.
12. Specify any **Hooks** to be used during the provisioning process. For more information, see [SAP ASE Hook Operations](#).
13. If your Delphix Engine system administrator has configured the Delphix Engine to communicate with an SMTP server, you will be able to specify one or more people to notify when the provisioning is done. You can choose other Delphix Engine users or enter email addresses.
14. Click **Submit**. When provisioning starts, the VDB will appear in the **Datasets** panel. Select the VDB and navigate to the **Status** tab to see the progress of the job. When provisioning is complete, more information can be seen on the **Configuration** tab.

## Provisioning a VDB from an encrypted SAP ASE database

This topic describes how to provision a VDB from an encrypted database.

The Delphix Engine supports provisioning from a dSource linked to a physical database that has been encrypted with SAP ASE Database Encryption, which can be used to encrypt columns or complete databases.

You can provision a VDB from a dSource linked to an encrypted database using the normal process to [Provision an SAP ASE VDB](#) but the user needs to ensure that the same key with the same name is present on the target instance as it was on the staging instance because we mount the database onto the target that was created on the staging instance. The keys should be imported from the source instance. Refer to configuration steps 4 and 5 of [Delphix Implementation of Database Encryption](#) to export and import the master and encryption key.

**Exception with suggested actions is raised in the following scenario:**

- If the required encryption key is not present on the target instance during the provisioning.

## Provisioning an SAP ASE VDB from a replicated VDB or dSource

This topic describes how to provision from a replicated dSource or virtual database (VDB). The process for provisioning from replicated objects is the same as the typical VDB provisioning process, except that first you need to select the **replica** containing the replicated object.

### Prerequisites

- You must have replicated a dSource or a VDB to the target host, as described in [Replication Overview](#)
- You must have added a compatible target environment on the target host

### Procedure

1. Login to the **Delphix Management** application for the target host.
2. Click **Manage**.
3. Select **Datasets**.
4. In the list of replicas, select the **replica** that contains the dSource or VDB you want to provision.
5. The provisioning process is now identical to the process for provisioning standard objects.

### Post-requisites

Once the provisioning job has started, the user interface will automatically display the new VDB in the live system.

## Resizing an SAP ASE VDB

When resizing ASE VDBs, we recommend:

- Ensure that the VDB's database devices reside on the Delphix storage, in the same directory as the database's other devices. Use the ASE "sp\_helpdb" and "sp\_helpdevice" commands to get details on the VDB's devices.
- If you need to add a new device, use the "skip\_alloc=true" clause because the storage on Delphix is already zeroed (initialized). This should allow the "DISK INIT" command to complete almost instantaneously.
- If you add a new device to the database by issuing the ASE "DISK INIT" followed by the "ALTER DATABASE" commands, click the camera icon to take a new snapshot of the VDB.  
**Note:** It is important to take a snapshot after altering the VDB's device layout so that Delphix rewrites the database's "manifest" file to include the new database device.
- Delphix 6.x uses the new "ALLOW\_DBID\_MISMATCH, FIXDBID" clause to fix in dbid mismatches on versions of ASE that support these clauses. If you are on an older version of Delphix or ASE that does not support this clause, you may be required to run the DBCC CHECKALLOC() command on the VDB.

If you use the ASE **ALTER DATABASE** command to increase the amount of space allocated to a VDB, you may need to run the **DBCC CHECKALLOC()** command on the VDB. If the VDB is unmounted and remounted without this command being run on it, you may run into the following ASE CR which leaves the VDB in an unusable state:

SAP ASE change request number	Description
798271	<p>The errors 14545, 14547 and 14519 will be raised by MOUNT DATABASE if the unmounted database had previously been mounted on a server where the database ID was used and a new database ID was assigned, and this database was extended without previously running DBCC CHECKALLOC(dbname, fix). Additionally, two new options have been added to the MOUNT command: WITH FIXDBID, to instruct the MOUNT command to fix any possible database ID mismatch, and WITH ALLOW_DBID_MISMATCH, to prevent that MOUNT DATABASE fails if the database has different database ID values in the allocation pages.</p> <p>The fix for this issue has been ported to <b>15.7 SP138</b> and <b>16.0 SP02 PL05</b>.</p>

### Determining the need to run DBCC CHECKALLOC

DBID mismatches are most likely to occur under the following circumstances:

- When provisioning VDBs to the same ASE instance hosting the staging database of the dSource the VDB was provisioned from.
- When provisioning multiple copies of the same VDB to the same ASE instance.

Delphix has found the following technique as a reliable way to determine whether or not you need to run DBCC CHECKALLOC() after increasing the amount of space allocated to the VDB.

In the following example, a VDB has been provisioned back to the same ASE instance where the staging database was being hosted. The staging database had a **dbid=11865**, so ASE automatically assigns the VDB the next lowest available dbid (**dbid=22** in this case).

1. Resize the database:

```

1> SELECT name, dbid FROM sysdatabases WHERE name = 'Vdb5'
2> go
name                                dbid
-----
Vdb5                                22

1> DISK RESIZE name="AAA4$ff367xUvd67P7II_db1_dev26", size="4M"
2> go

1> ALTER DATABASE Vdb5 on AAA4$ff367xUvd67P7II_db1_dev26="4M"
2> go
Extending database by 1024 pages (4.0 megabytes) on disk
AAA4$ff367xUvd67P7II_db1_dev26
Database Vdb5 which is currently offline has been altered from size 2816
logical pages (2816 physical pages) to 3840 logical pages

```

2. Run the following queries to determine if there is a dbid mismatch on the pages of the VDB. **DBCC PAGE()** requires the **sybase\_ts\_role** role.

```

1> -- Run a query to generate DBCC commands:
1> SELECT 'dbcc page (Vdb5,' + convert(varchar(5), lstart) + ', 0, 0)' FROM
master..sysusages WHERE dbid=db_id('Vdb5') AND segmap != 0
2> go

-----
dbcc page (Vdb5,0, 0, 0)
dbcc page (Vdb5,1536, 0, 0)
dbcc page (Vdb5,1792, 0, 0)
dbcc page (Vdb5,2816, 0, 0)

1> -- Turn on DBCC traceflag 3604 to direct output to stdout
2> dbcc traceon(3604)
3> GO

1> dbcc page (Vdb5,0, 0, 0)
2> dbcc page (Vdb5,1536, 0, 0)
3> dbcc page (Vdb5,1792, 0, 0)
4> dbcc page (Vdb5,2816, 0, 0)
5> go | grep dbid
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=0 dealloc_count=102 allocnode=0 ptnid=99 allocation_page dbid=11865
timestamp=0000 00002730, segmap=0x00000003 (0x00000002
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=1536 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=11865
timestamp=0000 00000001, segmap=0x00000004 (0x00000004
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=1792 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=11865
timestamp=0000 00000001, segmap=0x00000003 (0x00000002
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=2816 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=22
timestamp=0000 00000001, segmap=0x00000003 (0x00000002

```

**Notice that three pages (0, 1536 and 1792) have the staging database's dbid (11865) and one page (2816) has the correct dbid (22) that matches the dbid of 22 stored in sysdatabases.**

**If all the dbid's match the dbid in sysdatabases, there is no need to run DBCC CHECKALLOC().**

This means that DBCC CHECKALLOC() must be run on the VDB to correct the dbid mismatch:

```
1> dbcc checkalloc(Vdb5)
2> go
...etc...
11 allocation pages have been corrected to match database ID 22.
```

**Note: In the code block above 11 pages were fixed.**

Now if you run the **DBCC PAGE()** query again you can see that all of the dbid's match:

```
1> dbcc page (Vdb5,0, 0, 0)
2> dbcc page (Vdb5,1536, 0, 0)
3> dbcc page (Vdb5,1792, 0, 0)
4> dbcc page (Vdb5,2816, 0, 0)
5> go | grep dbid
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=0 dealloc_count=102 allocnode=0 ptnid=99 allocation_page dbid=22 timestamp=00
0 00002730, segmap=0x00000003 (0x00000002
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=1536 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=22 timestamp=00
00 00000001, segmap=0x00000004 (0x00000004
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=1792 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=22 timestamp=00
00 00000001, segmap=0x00000003 (0x00000002
    bmass_next=0x0 bmass_prev=0x0 bdbid=22
pageno=2816 dealloc_count=0 allocnode=0 ptnid=99 allocation_page dbid=22 timestamp=00
00 00000001, segmap=0x00000003 (0x00000002
```

### Recovering from DBID mismatch errors

If a VDB containing mismatched dbids gets unmounted, it will likely get ASE errors 14545, 14547 and 14519 during the next attempt to **MOUNT** it and it will now be in an unusable state. Options for recovery include:

- For ASE versions that do not have the fix for ASE CR 798271, you may rewind the VDB to a snapshot taken prior to resizing the VDB. Any data changes made since this point in time will be lost.

On newer versions of ASE where ASE CR 798271 has been fixed, you can manually mount the VDB using the new **MOUNT** command options:

```
1> -- Get the device listing for the VDB from the manifest
2> MOUNT DATABASE Vdb5 FROM '/export/home/sybase/toolkit/564dfe60-40b6-
aec9-26fb-3baeb4e7b23b-vdb-19/datafile/manifest' WITH LISTONLY
3> go
[database]
Vdb5
[device]
```

```

'/export/home/sybase/toolkit/564dfe60-40b6-aec9-26fb-3baeb4e7b23b-vdb-19/datafile/
dxnff367xUvd67P7II_db1_dev26' =
'AAA4$ff367xUvd67P7II_db1_dev26'
'/export/home/sybase/toolkit/564dfe60-40b6-aec9-26fb-3baeb4e7b23b-vdb-19/datafile/
dx9279VtfPAvf0m5xY_db1_dev27' =
'AAA5$279VtfPAvf0m5xY_db1_dev27'

1> -- Mount the VDB using the WITH ALLOW_DBID_MISMATCH clause
2> MOUNT DATABASE [Vdb5] AS [Vdb5] FROM '/export/home/sybase/toolkit/564dfe60-40b6-
aec9-26fb-3baeb4e7b23b-vdb-19/datafile/manifest'
3> WITH ALLOW_DBID_MISMATCH USING
4> '/export/home/sybase/toolkit/564dfe60-40b6-aec9-26fb-3baeb4e7b23b-vdb-19/datafile/
dxnff367xUvd67P7II_db1_dev26' = 'AAA4$ff367xUvd67P7II_db1_dev26',
5> '/export/home/sybase/toolkit/564dfe60-40b6-aec9-26fb-3baeb4e7b23b-vdb-19/datafile/
dx9279VtfPAvf0m5xY_db1_dev27' = 'AAA5$279VtfPAvf0m5xY_db1_dev27'
6> go
The physical device '/export/home/sybase/toolkit/564dfe60-40b6-
aec9-26fb-3baeb4e7b23b-vdb-19/datafile/dxnff367xUvd67P7II_db1_dev26'
has been automatically assigned the logical device name
'AAA6$ff367xUvd67P7II_db1_dev26'.

```

#### More information

VDBs are unmounted and remounted during operations such as:

- Disable/Enable of the VDB.
- Stop/Start of the VDB.
- Rebooting of the server hosting the VDB's ASE instance.

DBAs are unlikely to have found the need to run **DBCC CHECKALLOC()** on physical databases in the normal workflow of resizing a database unless the ASE **MOUNT/UNMOUNT** command is used. When you **MOUNT** a database on a server that already has the mounted database's dbid in use, ASE assigns the mounted database a new dbid and this gets reflected in the **sysdatabases** and **sysusages** tables in the master database and in the **dbtable** memory structure for the mounted database. However, the dbid in the dbinfo structure and allocation pages in the mounted database are not updated by mount. Doing so can take a long time on a big database. **DBCC CHECKALLOC()** will correct the values in all the allocation pages.

In Delphix version 5.1.3.0 and higher, Delphix will create databases using a high dbid (using the "CREATE DATABASE with dbid= " clause). By using a high dbid (ASE supports a maximum of 32,767 dbids), it is unlikely that the dbid will be reused and thus Delphix will be able to avoid the errors (14545, 14547 and 14519). It attempts to assign unique dbid values for staging databases in the range 10000-30000.

The second part of this fix involves keeping the staging database mounted so that the dbid is pinned and no other database gets created and uses the staging database's dbid. The staging database will remain mounted except for a brief window where we unmount it to create a manifest file.

The final part of this fix utilizes the ASE **DBCC PAGE()** command to confirm the dbid on select pages from the sysusages table all match the database's actual dbid. If there is a mismatch found, Delphix will call **DBCC CHECKALLOC()** to fix the database. Delphix calls **DBCC PAGE()** in order to avoid calling **DBCC CHECKALLOC()** as the **CHECKALLOC()** routine can add significant time to database recovery ([performance considerations for CHECKALLOC](#)).

## V2P with an SAP ASE dSource or VDB

### Requirements

This topic describes the procedure for exporting a virtual database (VDB) to a physical one, also known as V2P. Before performing the V2P operation, you must have created a database on the target instance into which you will load the exported data. It must be sufficiently large, and it must have been created with the **for load** SAP ASE option.

The Delphix Engine will initiate a load command using the database specified. The V2P operation will overwrite any existing data in this database. After a V2P operation takes place, the target physical database is no longer in FOR LOAD state.

### Procedure

1. Login to the **Delphix Management** application.
2. Select the **dSource** or **VDB** you want to export.
3. Select the **snapshot** of the dSource or VDB state you want to export.
4. Click **V2P**.
5. Select the **target environment**. The target environment should have been added to Delphix previously and should meet all target host requirements, see [Requirements for SAP ASE Environments and Databases](#).
6. Under **Installation**, select which **instance** that you want to export to.
7. Enter the **Name** of the database on the target instance into which you want to load the exported data.
8. Select whether or not to **Run Recovery After V2P**. When this option is set, the Delphix Engine will online the database when the export is done.
9. Click **Next**.
10. Select whether you want to have an email sent to you when the export process completes.
11. Click **Submit**.

## Deleting an SAP ASE VDB

### Procedure

Deleting a VDB is an unrecoverable operation. Proceed only if you want to permanently destroy the unique data that was created in the VDB.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **VDB** that you want to delete.
5. From the Actions menu (...) select **Delete**.
6. If stopping or starting the VDB requires particular credentials for the target environment other than those of the default environment user:
  - a. Check **Provide Privileged Credentials**.
  - b. Enter the **username** and **password**.
  - c. Click **Validate Credentials**.
7. Click **Delete** to confirm that you want to delete the VDB.

If the VDB was currently active, the Delphix Engine will shut it down, unmount all filesystems from the target environment, and finally delete the VDB itself.

## Enabling and disabling SAP ASE VDBs

This topic describes how to enable and disable a virtual database (VDB).

Disabling a VDB is a pre-requisite for procedures such as VDB migration or upgrade. Disabling a VDB removes all traces of it, including any configuration files, from the target environment to which it was provisioned. When you later enable the VDB again, these configuration files are restored on the target environment.

### Procedure

1. Click **Manage**.
2. Select **Datasets**.
3. Click the **VDB** you want to disable.
4. From the Actions menu (...) select **Disable**.
5. Click **Disable** to acknowledge the warning.

When you are ready to enable the VDB again, from the Actions menu (...) select **Enable**, and the VDB will continue to function as it did previously.

## Migrating an SAP ASE VDB

This topic describes how to migrate a virtual database (VDB) from one target environment to another.

In certain situations, you may want to migrate a VDB to a new target environment. For example:

- When upgrading the host on which the VDB resides
- During a general data center migration
- To distribute the VDB load across target environments

This is easily accomplished by first disabling the database, then using the Migrate VDB feature to select a new target environment.

### Prerequisites

- You must first disable the VDB before migrating it. Follow the steps outlined in [Enabling and Disabling SAP ASE VDBs](#)
- You must have already set up a new target environment that is compatible with the VDB that you want to migrate.

### Procedure

1. Login to your Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **VDB** you want to migrate.
5. From the **Actions** menu (...) select **Disable**.
6. Click **Disable** to confirm.
7. From the **Actions** menu (...) select **Migrate**.
8. In the Migrate window select:
  - a. Environment: the new **target environment** for the VDB
  - b. User: select a user
  - c. Installation: the **installation** where you want to migrate
9. Click Migrate to confirm your selections.
10. From the **Actions** menu (...) select **Enable**.
11. Click **Enable** to confirm.

Within a few minutes, your VDB will re-start in the new environment, and you can continue to work with it as you would with any other VDB.

## Refreshing an SAP ASE VDB

This topic describes how to manually refresh a virtual database (VDB).

Refreshing a VDB will re-provision it from the dSource. As with the normal provisioning process, you can choose to refresh the VDB from a snapshot or a specific point in time. However, you should be aware that refreshing a VDB would delete any changes that have been made to it over time. When you refresh a VDB, you are essentially re-setting it to the state you select during the refresh process. You can refresh a VDB manually, as described in this topic, or you can set a VDB refresh policy, as described in [Managing Policies](#)

**i** Although the VDB no longer contains the previous contents, the previous Snapshots and Timeflow still remain in Delphix and are accessible through the Command Line Interface (CLI).

### Prerequisites

To refresh a VDB, you must have the following permissions:

- **PROVISIONER** permissions on the dSource associated with the VDB
- **PROVISIONER** permissions on the group that contains the VDB
- **Owner** permissions on the VDB itself
- **Data** is a role that allows DB\_ROLLBACK, DB\_REFRESH, READ\_ACTION, DB\_SYNC, JOB\_CANCEL.
- **Read** is a role that allows the user to inspect objects via the READ\_ACTION permission.

A user with admin credentials can perform a VDB Refresh on any VDB in the system.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **VDB** you want to refresh.
5. Click the **Refresh VDB** button.

6. Select **More Accurate** and **Next**.
7. **Refresh VDB**

Select the desired **refresh point** snapshot or click the **down arrow** icon to choose the Latest available range, A point in time, or An SCN to refresh from.

Refresh VDB

8. Click **Next**.
9. Click **Submit** to confirm.

Refresh VDB

10. Click the **Actions** link to watch the progress of the refresh job.
11. To see when the VDB was last refreshed/provisioned, check the **Time Point** on the Status page

## Rewinding an SAP ASE VDB

This topic describes the procedure for rewinding an SAP ASE virtual database (VDB).

Rewinding a VDB rolls it back to a previous point in its TimeFlow and re-provisions the VDB. The VDB will no longer contain changes that were made after the rewind point.

**i** Although the VDB no longer contains changes made after the rewind point, the rolled-over snapshots and TimeFlow still remains in Delphix and are accessible through the Command Line Interface (CLI). See the topic [CLI Cookbook: Rolling Forward a VDB](#) for instructions on how to use these snapshots to refresh a VDB to one of its later states after it has been rewound.

### Prerequisites

To rewind a VDB, you must have the following permission:

- **Owner** permissions on the VDB itself

You do NOT need owner permissions for the group that contains the VDB. A user with Delphix Admin credentials can perform a VDB rewind on any VDB in the system.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **VDB** you want to rewind.
5. Click the **TimeFlow** tab.
6. Select the rewind point as a snapshot or a point in time.
7. Click **Rewind**.
8. If you want to use login credentials on the target environment other than those associated with the environment user, click **Provide Privileged Credentials**.
9. Click **Yes** to confirm.

**i** You can use TimeFlow bookmarks as the rewind point when using the CLI. Bookmarks can be useful to:

- Mark where to rewind to – before starting a batch job on a VDB, for example.
- Provide a semantic point to revert back to, in case the chosen rewind point turns out to be incorrect.

For a CLI example using a TimeFlow bookmark, see [CLI Cookbook: Provisioning a VDB from a Timeflow Bookmark](#).

## Upgrading SAP ASE VDBs

This topic describes how to upgrade an SAP ASE VDB to a higher version of SAP ASE instance.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **VDB** to be upgraded.
5. From the **Actions** menu (...) select **Disable**.
6. Click **Disable** to confirm.
7. Upgrade the ASE instance(s) hosting the VDBs.
8. Click the **Refresh** icon ( under the **Manage > Environments** menu ) to refresh the Delphix environment hosting the VDBs so that Delphix registers the new version of ASE.
9. Enable the VDB. The VDBs will be upgraded the first time they're enabled.
10. Repeat steps 4 to 9 for each VDB you want to upgrade.

## Backup server best practices

- The backupserver log should have read permissions for the Delphix environment user
- Dump file names should be unique per source backup server.
- Dumps should be done to a local backupserver. Dumps done using the “at <backupserver>” syntax are not discovered and ingested/applied.
- Dumps of production databases that use the same backup server and same load backup path should be available on the same staging host that was pointed at during the link
- If using a remote backup server as load location, make sure “interfaces” file changes are done to ensure staging host backupserver can communicate with the remote backup server.
- A user running backupserver or process owner of the backupserver on the staging host should have read access for all the dump files that belong to dSources that use this backupserver.

## Recommendations/best practices

1. Name the dump files as unique as possible.
2. Delphix recursively searches for backup files in a given load backup path. So assign or choose the load backup path for a given dSource to be as specific and unique as possible. For e.g, if the load backup path is /dumps for dSource db1, but the database dumps are copied to /dumps/db1, choose /dumps/db1 instead to avoid duplicate files that can happen with other dSources or databases.
3. Avoid linking sources where it's backup location is a child directory of another dSource's backup location. Ideally, each dSource using the same staging host should have its backup path set to sibling directories for ease of search.
4. Avoid copying files (of any type) with the same name as backup files that are being ingested.
5. Avoid copying other dSource or database backups to the same load backup path of the dSource of interest. You can copy, as long as dump file names are unique.
6. Only use a remote backup server as the load location if dumps cannot be available on the staging host.
7. Avoid, if possible, using production backup server as load location and the backup files are on production host when configuring a dSource with remote backupserver.
8. DE by default assumes backup files are available on the staging host when searching for them. If the backup files are available on the staging host, avoid using the remote backupserver option on the link/data management wizard.
9. If validated sync reports any fault, look at other faults that were raised, resolve all of them as well along with the current fault.
10. When copying striped backups to staging, keep all stripes in the same location.
11. If possible, create separate database dumps and/or transaction logs by more than 1 minute apart so that the dump header name is unique.
12. The Delphix Engine, by default, looks for backups that happened within the last six months from the current date/time when a source database is linked for the first time
  - a. If there is ever a need to ingest an older backup, use “Specific Backup” sync parameters and specify the location of the backup files to ingest.
  - b. Please reach out to Delphix Support for help if there is a reason for concern regarding the 6 months window.
13. The Delphix Engine periodically purges discovered backup files from its internal catalog that are older than 6 months (default). If there is a need to ingest an old backup, use the “Specific Backup” option as there is no mechanism to rediscover old backups.

## SAP ASE hook operations

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at `/bin/sh`. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a `bash` binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of RunBash Operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
```

```
# Bashisms are safe here!  
if [[ -d "$remove_dir" ]]; then  
    rm -rf "$remove_dir" || exit 1  
fi  
  
exit 0
```

## Shell operation tips

### Using `nohup`

You can use the `nohup` command and process backgrounding from resource in order to "detach" a process from the Delphix Engine. However, if you use `nohup` and process backgrounding, you MUST redirect `stdout` and `stderr`.

Unless you explicitly tell the shell to redirect `stdout` and `stderr` in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either `stdout` or `stderr`. Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your `RunCommand` operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad Examples

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

#### Good Examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs which normally can only be used interactively, such as `ssh`. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Management application and CLI to aid in debugging.

If successful, the script must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

Example of a RunExpect operation

Start an ssh session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
  -re {Password: } {
    send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
  }
  timeout {
    puts "Timed out waiting for password prompt."
    exit 1
  }
}
exit 0
```

### SAP ASE environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set environment variables so that the user-provided operations can use them to access the dSource or VDB.

#### dSource environment variables

Environment variables	Description
ASE_ENVUSER	Environment username for the dSource
ASE_DBUSER	Database username for the dSource
ASE_DATABASE	Database name for the dSource
ASE_INSTANCE	SAP ASE Instance name for the dSource
ASE_PORT	SAP ASE Instance port for the dSource

## VDB environment variables

Environment variables	Description
ASE_ENVUSER	Environment username for the VDB
ASE_DBUSER	Database username for the VDB
ASE_DATABASE	Database name for the VDB
ASE_INSTANCE	SAP ASE Instance name for the VDB
ASE_PORT	SAP ASE Instance port for the VDB

## Staging server environment variables

Environment variables	Description
ASE_ENVUSER	

## Support for dump history file

### Overview

Prior to ASE version 15.7 ESD#2, ASE did not provide any structured information about backup/restore operations performed on databases. Delphix relied on the backup server log file to find information about any backups performed using a particular backup server. The Delphix Engine parsed this log file, read each backup file to find which database the backup belonged to and restored the ones required for linked databases. As backup information is not very structured in this log file, getting backup history from this file resulted in the collection and parsing of unnecessary data. Starting with ASE 15.7 ESD#2, users can enable an option at the ASE instance level to record all backup and restore operations in a particular file, known as the Dump History file. Backup and restore operation information is stored in this file in a structured way and can be reliably used to get information about backups performed on a given database. When Dump History is enabled for a linked source, Delphix will use this feature to get information about backups for all sync operations including validated sync.

### Prerequisites

To use this feature, Dump history needs to be enabled at the ASE Source instance level.

### Linking a database with dump history enabled

By default, Delphix uses the backup server log file to discover backup information. Users can switch to Dump History by explicitly enabling it for the dSource. Before linking a database with Dump History enabled, make sure that Dump History is enabled on the source ASE instance. To enable Dump History for the database being linked, go through the linking wizard and on the **Data Management** page, check the box marked "Use Dump History".

The screenshot shows the 'Add dSource' wizard in the 'Data Management' step. On the left is a navigation pane with steps: Source, dSource Configuration, **Data Management** (selected), Policies, Hooks, and Summary. The main area is titled 'Data Management' with the subtitle 'Configure and Administer data details.' It contains several configuration options:

- Initial Load:** Radio buttons for 'New Full Backup', 'Most Recent Existing Full Backup' (selected), and 'Specific Existing Full Backups'.
- Backup Path:** A text input field containing '/work'.
- Staging Environment @:** A dropdown menu showing 'ASE\_RH74SRC'.
- Repository:** A dropdown menu showing 'ASE157\_SRC'.
- Validated Sync Mode:** A checked checkbox labeled 'Enabled'.
- Use Dump History:** A checked checkbox labeled 'Enabled'.
- LogSync:** An unchecked checkbox labeled 'Enabled'.

At the bottom right of the form are four buttons: 'Cancel', 'Back', 'Next' (highlighted in blue), and 'Submit'.

## SQL Server environments and data sources

This section covers the following topics:

- [Delphix architecture with SQL Server](#)
- [Quick start guide for SQL Server \(Microsoft SQL Server on Windows\)](#)
- [SQL Server support and requirements](#)
- [Managing SQL Server environments and hosts](#)
- [Linking data sources and syncing data with SQL Server](#)
- [Provisioning and managing virtual databases with SQL Server](#)
- [Hooks for SQL Server](#)
- [Using hostChecker to validate target database servers](#)

## Delphix architecture with SQL Server

SQL Server is Microsoft's relational database which is typically run on Windows Server hosts. With Delphix, you can use various SQL Server configurations, ranging from Failover Clusters to Availability Groups. In this section, you'll find an overview of how Delphix works with SQL Server.

There are three key concepts when using Delphix with any data platform:

1. Environments: The server and software required to run a data set.
  - a. Source Environment: Source data to be ingested into Delphix. These will be used to create dSources.
  - b. Target Environment: Target hosts to provision VDBs.
2. dSources: A database that the Delphix Virtualization Engine uses to create and update or maintain virtual copies of your database
3. VDBs: A database provisioned from either a dSource or another VDB which is a copy of the source data. A VDB is created and managed by the Delphix Virtualization Engine.

With these concepts in mind, let's explore how Delphix connects to SQL Server environments and creates SQL Server dSources and VDBs.

## Staging push mechanism with SQL Server

Starting Delphix Engine version 6.0.13.0 a new data ingestion mechanism has been introduced that will help users to push data into the staging database on their own.

The previous data ingestion mechanism of the SQL Server has a few limitations like dependency on the source access and limited backup vendor's support. Currently, Delphix supports Native, Commvault, NetBackup, Lightspeed, and Redgate backup vendors.

With Staging Push implementation, we have removed the dependency of accessing the customer's production database and also enabled the customers who are using the backup vendors that Delphix does not support.

To summarize the Staging Push mechanism.

- Customers now have ownership of the staging databases.
- Customers are now responsible to keep the staging database in sync with the source database. Note that the database files of the staging database are stored on Delphix Storage.
- Delphix is still responsible to snapshot the underlying data files and gathering any metadata required for provisioning from the snapshots.

## Delphix in multi-domain windows environments

### General Overview

When considering the Delphix logical architecture, there are four primary components:

1. Source host(s)
2. Continuous Data Engine
3. VDB Target host(s)
4. Staging Target Host(s)

In SQL Server environments, the staging target host is used for staging data from the source database on the source host into Delphix. Although you can use any VDB target host on which the Delphix Connector service has been installed for this purpose, Delphix recommends a dedicated Staging Target Host for load isolation and separation of roles.

This page focuses on the process of getting source SQL Server data into the storage of the Continuous Data Engine (DVE) via the Staging Target Host.

When considering SQL Server deployments in different enterprise environments, we often see cases where the production, development, test, or reporting environments exist in different Windows domains which may or may not have trust relationships. Such varying domain approaches can come into play due to security, organizational, geographical, or other technical reasons, and can make communication between Windows hosts more complicated to manage. Delphix is flexible enough to work in many configurations, but we want to help you choose the solution that best suits your unique environment.

We listed the four primary components of the Delphix logical architecture for SQL Server above. In addition, a fifth component in the Delphix logical architecture might be considered for use-cases #3, #4, and #5 in the Technical Overview below: a Connector host. The function of the Delphix Connector on that host is the discovery of the source environment via remote registry and ODBC calls. There are no Delphix software installation requirements for Windows source hosts, but it might be helpful to note this role can co-reside directly on the Windows source host for consolidation purposes if desired.

### Technical overview

Keep in mind that the Delphix Engine is always syncing with backups of the source database. It is never the live data that is ingested; it is always backups of different flavors.

If SQL Server simple recovery mode is used, these can be full or differential backups initiated by the source database. If full recovery mode is enabled, the Delphix Engine will typically leverage only transaction log backups after the initial data load. Again, the source database would initiate backups, and the Delphix Engine would collect the backup files that have been created by SQL Server. This approach of using transaction logs minimizes spikes in system load by ingesting smaller backups more often. Another option is copy-only backups, which the Delphix Engine initiates in a configuration known as Delphix Managed Backups. For more information refer to [Delphix as a Backup Solution to SQL Server](#).

Delphix can ingest database and log data from native backups, as well as a number of third-party backup products. SQL Server restores the backups onto the shared Delphix storage on the staging target host running the databases in recovery mode. We call this process “validated sync,” which is why you may hear the staging target also referred to as a validated sync server.

It is important to note that the Continuous Data Engine (based on DxOS, itself derived from a UNIX-based OS) is not a domain member itself. The credentials we discuss in this document are between Windows servers, and the key domain-specific authentication is between the staging host and the UNC path to the SMB share where the backup data is stored.

In the rest of this section, we will describe multiple scenarios. Review them to determine which will fit best in your environment.

Case 1: Staging target in test environment

In this case, we will review an environment with two domains: PRODUCTION and TEST, which have a domain trust relationship. This is one of the simplest and most straightforward approaches, as illustrated in the *Staging Target in Test Environment diagram below.*

In this example, the staging target host exists in the non-production TEST domain, but because of domain trust, accounts located in that domain can access resources in the PRODUCTION domain. This would allow the staging target host to connect to the PRODUCTION source host both for environment discovery and to the shared backup location “\source\backups” over Server Messaging Block (SMB) to access database and transaction log backups.

Case 1: Staging Target in Test Environment

Protocol & Port Connection information
SMB/445 – Server Messaging Block (file transfer)
iSCSI 3260/tcp – TCP network storage traffic initiated from the target
JDBC 1433/tcp – Get version, backup history, and LSN data
Delphix Connector v1 9100/tcp – Custom control and data specific to the Delphix Engine
DSP 8415/tcp - Delphix Session Protocol connections (Optionally needed for features like Windows Authentication, Netbackup/Commvault Support)
Remote Registry 445/tcp – Discovery of SQL instances and ports
* JDBC Connectivity is needed to the Source Database:
- directly from Delphix Engine if using Sql Authentication
- from Staging/Connector Host if using Windows Authentication

*Staging Target in Test Environment*

Case 2: Staging target in production environment

The scenario illustrated in the *Staging Target in Production Environment diagram below* shows a TEST domain that does not have access to resources in the PRODUCTION domain. However, the customer has determined that Delphix VDBs must be provisioned to the TEST domain. In this scenario, you can use the staging target host in the PRODUCTION domain to link to the PRODUCTION database and perform the normal restore of the DB and/or log files to the Delphix storage. You can then provision VDBs in the TEST domain.

In this case, VDBs can be completely isolated from the PRODUCTION domain, and there is no requirement for hosts in the TEST domain to have any direct access to resources in the PRODUCTION domain.

Case 2: Staging Target in Production Environment

**Protocol & Port Connection information**  
 SMB/445 – Server Messaging Block (file transfer)  
 iSCSI 3260/tcp – TCP network storage traffic initiated from the target  
 JDBC 1433/tcp – Get version, backup history, and LSN data  
 Delphix Connector v1 9100/tcp – Custom control and data specific to the Delphix Engine  
 DSP 8415/tcp - Delphix Session Protocol connections (Optionally needed for features like Windows Authentication, Netbackup/Commvault Support)  
 Remote Registry 445/tcp – Discovery of SQL instances and ports  
 \* JDBC Connectivity is needed to the Source Database:  
 - directly from Delphix Engine if using Sql Authentication  
 - from Staging/Connector Host if using Windows Authentication

Staging Target in Production Environment

Case 3: Domain-agnostic storage

This example shows a shared backup location that is not dependent on trust relationships between the PRODUCTION and TEST domains. Because Delphix uses UNC paths, it can support any protocol which provides UNC access for that backup data access – for example, SMB or iSCSI.

This is shown by the *Domain-agnostic Storage* diagram below by the arrow – stretching from bottom-left toward the upper-right and crossing the domain boundary – representing any UNC-compatible protocol connecting the staging target host to the data on the NAS host. Provided that the Delphix environment users on both the source host and staging target host have read/write access to the shared backup location on network-attached storage (NAS), the SQL Server instance running on the staging target host will be able to access the backup files needed.

Although this option is not specific to this case, you may notice we separated a connector role to its own connector host. As you can infer from the diagram, the Delphix Connector’s primary function on that host is the discovery of the source environment via remote registry and ODBC calls. Despite the fact that there are no software installation requirements for the source hosts in PRODUCTION, it may be helpful to note that you can even install this role directly on the source server for consolidation if you want to.

**Protocol & Port Connection information**  
 SMB/445 – Server Messaging Block (file transfer)  
 iSCSI 3260/tcp – TCP network storage traffic initiated from the target  
 JDBC 1433/tcp – Get version, backup history, and LSN data  
 Delphix Connector v1 9100/tcp – Custom control and data specific to the Delphix Engine  
 DSP 8415/tcp - Delphix Session Protocol connections (Optionally needed for features like Windows Authentication, Netbackup/Commvault Support)  
 Remote Registry 445/tcp – Discovery of SQL instances and ports  
 \* JDBC Connectivity is needed to the Source Database:  
 - directly from Delphix Engine if using Sql Authentication  
 - from Staging/Connector Host if using Windows Authentication

Case 3: Domain-agnostic Storage

*Domain-agnostic Storage*

Case 4: Migrating backup files

In this somewhat more complex configuration, backup files are sent to storage in the PRODUCTION domain, while the host used to link to the source and perform the validated sync is in an isolated TEST domain. We have used a separate connector host in the PRODUCTION domain again, to perform the environment discovery of the source host there. Backup files for SOURCE are being stored on NAS.

We will link using the Staging Target Host and create VDBs in the TEST domain. When the Delphix Engine discovers that a new backup of PRODUCTION has been taken, it will attempt to find the relevant files in the shared backup location provided during linking. It does this by periodically performing a recursive search for the file names on the shared backup location. If it does not find the specific files, it will try again later. Knowing this, we can specify a shared backup location in the TEST domain and set up an automated process to copy the backup files from \nas\backups in the PRODUCTION domain to \staging\backups in the TEST domain. We can use any copy mechanism to transfer the files, such as FTP or ROBOCOPY. The files must be available long enough for the Delphix Engine to detect and apply them to the recovery database on the Staging Target Host before removal.

We have customers who also use this model in cases with multiple data centers (on-premise deployments) or virtual private clouds (cloud deployments) rather than multiple domains. These customers want database and transaction log backups to be available in secondary data centers or private clouds, but they want to make sure that the data is only copied over the WAN once.

**Protocol & Port Connection information**  
 SMB/445 – Server Messaging Block (file transfer)  
 iSCSI 3260/tcp – TCP network storage traffic initiated from the target  
 JDBC 1433/tcp – Get version, backup history, and LSN data  
 Delphix Connector v1 9100/tcp – Custom control and data specific to the Delphix Engine  
 DSP 8415/tcp - Delphix Session Protocol connections (Optionally needed for features like Windows Authentication, Netbackup/Commvault Support)  
 Remote Registry 445/tcp – Discovery of SQL instances and ports  
 \* JDBC Connectivity is needed to the Source Database:  
 - directly from Delphix Engine if using Sql Authentication  
 - from Staging/Connector Host if using Windows Authentication

Case 4: Migrating Backup Files

Migrating Backup Files

Case 5: SMB anonymous access

In this example (shown by the *SMB Anonymous Access* diagram below), a Windows SMB connection is traversing domains that do not have a trust relationship. This approach is problematic because there is no simple configuration for SMB file sharing that does not rely on domain trusts. As a result, there is no way to specifically grant accounts in the TEST domain access to SMB shares in the PRODUCTION domain.

Because such users cannot be authenticated, they are treated as “anonymous” users and do not have permission to any resources by default.

Windows provides an “Everyone” group. However, this group still only applies to accounts that can be authenticated in the domain, so you cannot use that group in this case. There is still a way to configure access to the shared backup location on \\source\backups by accounts in other domains, such as TEST. However, because it relies on anonymous access, you will need to consider the security implications of enabling this method, as well as measures that could mitigate any additional risk in your environment – for example, a private VLAN or IPSEC between hosts.

1. Enable the “Guest” account on the server source Server – for example, **SQLPROD**.
2. Create a share where full and transaction log backups will be stored – for example, **SQLPROD\backups**.
3. Configure read-only security access for both the folder security permissions on the shared directory and the share permissions for the “guest” account.

Case 5: SMB Anonymous Access

**Protocol & Port Connection information**  
 SMB/445 – Server Messaging Block (file transfer)  
 iSCSI 3260/tcp – TCP network storage traffic initiated from the target  
 JDBC 1433/tcp – Get version, backup history, and LSN data  
 Delphix Connector v1 9100/tcp – Custom control and data specific to the Delphix Engine  
 DSP 8415/tcp - Delphix Session Protocol connections (Optionally needed for features like Windows Authentication, Netbackup/Commvault Support)  
 Remote Registry 445/tcp – Discovery of SQL instances and ports  
 \* JDBC Connectivity is needed to the Source Database:  
 - directly from Delphix Engine if using Sql Authentication  
 - from Staging/Connector Host if using Windows Authentication

*SMB Anonymous Access*

Here are some additional links from Microsoft that relate to anonymous sharing:

- [Network access: Let Everyone permissions apply to anonymous users](#)
- [Network access: Shares that can be accessed](#)

## Quick start guide for SQL Server (Microsoft SQL Server on Windows)

This quick start guide, which is excerpted from the larger User Guide, is intended to provide you with a quick overview of working with SQL Server database objects in the Delphix Engine. It does not cover any advanced configuration options or best practices, which can have a significant impact on performance. It assumes that you are working in a Lab/Dev setting and attempting to quickly test Delphix functionality. It assumes you will use the VMware Hypervisor. It assumes you are running supported combinations of software as explained here: [Supported OS, SQL Server, and Backup Software Versions for SQL Server](#).

### Overview

In this guide, we will walk through deploying a Delphix Engine, starting with configuring Source, Staging (aka Validated Sync), and Target database environments on Windows servers. We will then create a dSource, and provision a VDB.

The following diagram describes the engine topology for SQL Server environments. It illustrates the recommended ports to be open from the engine to remote services, to the Delphix Engine, and to the Source, Target and Validated Sync Environments.

 Port 1433 is required between the Delphix Engine and AG (Availability Group) cluster sources.

For purposes of the QuickStart, you can ignore any references to Replication or Masking, such as the engines shown in the diagram below.

**Note:** SQL Server listener typically runs on TCP 1433. In cases where other ports are used, substitute for 1433 above.  
**\*\*Port 1433 access to Source Database Host from Delphix Engine is needed only for SQL Authentication. It is not needed in case of Windows Authentication.**

### Deploy OVA on VMware

Use the Delphix-supplied OVA file to install the Delphix Engine. The OVA file is configured with many of the minimum system requirements. The underlying storage for the install is assumed to be redundant SAN storage.

1. Download the OVA file from <https://download.delphix.com>. You will need a support login from your sales team or a welcome letter.
  - a. Navigate to the Delphix Product Releases/ /appliance="" images="">
2. Login using the vSphere client to the vSphere server (or vCenter Server) where you want to install the Delphix Engine.
3. In the vSphere Client, click **File**.
4. Select **Deploy OVA Template**.
5. Browse to the OVA file.
6. Click **Next**.
7. Select a **hostname** for the Delphix Engine. This hostname will also be used in configuring the Delphix Engine network.
8. Select the **data center** where the Delphix Engine will be located.
9. Select the **cluster** and the **ESX host**.
10. Select one (1) **data store** for the **Delphix OS**. This datastore can be **thin-provisioned** and must have enough free space to accommodate the 127GB comprising the Delphix operating system.
11. Select four (4) or more **data stores** for Database Storage for the Delphix Engine. The Delphix Engine will stripe all of the Database Storage across these VMDKs, so for optimal I/O performance, each VMDK must be

equal in size and be configured **Thick Provisioned - Eager Zeroed**. Additionally, these VMDKs should be distributed as evenly as possible across all four SCSI I/O controllers.

12. Select the **virtual network** you want to use.

If using multiple physical NICs for link aggregation, you must use vSphere NIC teaming. Do not add multiple virtual NICs to the Delphix Engine itself. The Delphix Engine should use a single virtual network. For more information, see [Optimal Network Architecture for the Delphix Engine](#).

13. Click **Finish**. The installation will begin and the Delphix Engine will be created in the location you specified.
14. Once the installation has completed, power on the Delphix Engine and proceed with the initial system configuration as described in [Setting Up Network Access to the Delphix Engine](#).

**i** If your source database is 4 TB, you probably need 4 TB of storage for the Delphix Engine. Add at least 4 data disks of similar size for the Delphix VM. For example: for a source database of 4 TB, create 4 VMDKs of 1 TB each.

**i** For a full list of requirements and best practice recommendations, see [Virtual Machine Requirements for VMware Platform](#).

#### Setup network access to Delphix engine

1. Power on the Delphix Engine and open the Console.
2. Wait for the Delphix Management Service and Delphix Boot Service to come online. This might take up to 10 minutes during the first boot. Wait for the large orange box to turn green.
3. Press any key to access the sysadmin console.
4. Enter `sysadmin@SYSTEM` for the username and `sysadmin` for the password.
5. You will be presented with a description of available network settings and instructions for editing.

##### Delphix Engine Network Setup

To access the system setup through the browser, the system must first be configured **for** networking in your environment. From here, you can configure the primary **interface**, DNS, hostname, and **default** route. When DHCP is configured, all other properties are derived from DHCP settings.

To see the current settings, run `"get."` To change a property, run `"set <property>=<value>."` To commit your changes, run `"commit."` To exit **this** setup and **return** to the standard CLI, run `"discard."`

`defaultRoute` IP address of the gateway **for** the **default** route -- **for** example, `"1.2.3.4."`

`dhcp` Boolean value indicating whether DHCP should be used **for** the primary **interface**. Setting **this** value to `"true"` will cause all other properties (address, hostname, and DNS) to be derived from the DHCP response

`dnsDomain` DNS Domain -- **for** example, `"delphix.com"`

```

    dnsServers      DNS server(s) as a list of IP addresses -- for example,
"1.2.3.4,5.6.7.8."

    hostname        Canonical system hostname, used in alert and other logs --
for example, "myserver"

    primaryAddress  Static address for the primary interface in CIDR notation
-- for example, "1.2.3.4/22"

```

Current settings:

```

defaultRoute: 192.168.1.1
dhcp: false
dnsDomain: example.com
dnsServers: 192.168.1.1
hostname: Delphix
primaryAddress: 192.168.1.100/24

```

- Configure the `hostname`. If you are using DHCP, you can skip this step. **Note**: Use the same `hostname` you entered during the server installation.

```
delphix network setup update *> set hostname=<hostname>
```

- Configure DNS. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set dnsDomain=<domain>
delphix network setup update *> set dnsServers=<server1-ip>[,<server2-ip>,...]
```

- Configure either a static or DHCP address. **Note** The static IP address must be specified in CIDR notation (for example, `192.168.1.2/24`)

- DHCP Configuration

```
delphix network setup update *> set dhcp=true
```

- Static Configuration

```
delphix network setup update *> set dhcp=false
delphix network setup update *> set primaryAddress=<address>/<prefix-len>
```

- Configure a default gateway. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set defaultRoute=<gateway-ip>
```

- Commit your changes. Note that you can use the `get` command prior to committing to verify your desired configuration.

```
delphix network setup update *> commit
```

Successfully committed network settings. Further setup can be done through the browser at:

`http://<address>`

Type "exit" to disconnect, or any other commands to **continue** using the CLI.

11. Check that you can now access the Delphix Engine through a Web browser by navigating to the displayed IP address, or hostname if using DNS.
12. Exit setup.

```
delphix> exit
```

## Setting up the Delphix engine

Once you set up the network access for Delphix Engine, navigate to the Delphix Engine URL in your browser for server setup.

The welcome screen below will appear for you to begin your Delphix Engine setup.

### Virtualization Setup

**Welcome**

Choose engine type to setup:

- Virtualization
- Masking

This wizard will step you through the setup. During this process you will complete the following:

- Create your password for the default "sysadmin" user
- Set the system time
- Configure network and services
- Configure the storage pool
- Configure proxies, SMTP, and LDAP (these are optional)
- Register your software

After setup is complete, you will have two administrators defined:

- The system administrator, "sysadmin" with the password you defined. This will be the system administrator for the instance.
- The engine administrator, "admin" with the password you defined. This is typically a DBA who will administer all the data managed by the instance.

When setup is complete, log in as engine administrator to begin using your engine.

The setup procedure uses a wizard process to take you through a set of configuration screens:

- Administrators
- Time
- Network
- Network Security
- Storage
- Outbound Connectivity
- Authentication
- Network Authorization
- Registration
- Summary

1. Connect to the Delphix Engine at `http://login/index.html#serverSetup`.  
The **Delphix Setup** application will launch when you connect to the server.  
Enter your **sysadmin** login credentials, which initially defaults to the username **sysadmin**, with the initial default password of **sysadmin**. On first login, you will be prompted to change the initial default password.
2. Click **Next**.

## Administrators

The Delphix Engine supports two types of administrators:

- System Administrator (**sysadmin**) - this is the engine system administrator. The sysadmin password is defined here.
- Engine Administrator (**admin**) - this is typically a DBA who will administer all the data managed by the engine.

On the Administrators tab, you set up the sysadmin password by entering an email address and password. The details for the admin are displayed for reference.

 The default domain user created on Delphix Engines from 5.3.1 is known as **admin** instead of `delphix_admin`. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling `delphix_admin`.

## System time

The engine time is used as the baseline for setting policies that coordinate between virtual databases and external applications.

Choose your option to set up system time in this section. For a Quick Start, simply set the time and your timezone. You can change this later.

## Network

The initial out-of-the-box network configuration in the OVA file is set to use a single VMXNET3 network adapter.

You have already configured this in the initial configuration. Delphix supports more advanced configurations, but you can enable those later.

## Storage

You should see the data storage VMDKs or RDMs you created during the OVA installation. Click **Next** to configure these for data storage.

## Serviceability

Choose your options to configure serviceability settings.

For a Quick Start, accept the defaults. You can change this later.

## Authentication

Choose your options to configure authentication services.

For a Quick Start, accept the defaults. You can change this later.

## Registration

If the Delphix Engine has access to the external Internet (either directly or through a web proxy), then you can auto-register the Delphix Engine:

1. Enter your **Support Username** and **Support Password**.
2. Click **Register**.

If external connectivity is not immediately available, you must perform manual registration.

1. Copy the **Delphix Engine registration code** in one of two ways:
  - a. Manually highlight the registration code and copy it to clipboard. Or,
  - b. Click **Copy Registration Code to Clipboard**.
2. Transfer the Delphix Engine's registration code to a workstation with access to the external network Internet. For example, you could e-mail the registration code to an externally accessible e-mail account.
3. On a machine with access to the external Internet, please use your browser to navigate to the Delphix Registration Portal at <http://register.delphix.com>.
4. Login with your Delphix support credentials (username and password).
5. Paste the **Registration Code**.
6. Click **Register**.

 Although your Delphix Engine will work without registration, we strongly recommend that you register each Delphix Engine as part of the setup. Failing to register the Delphix Engine will impact its supportability and security in future versions

To regenerate the registration code for a Delphix Engine please refer to, [Regenerating the Delphix Engine Registration Code](#). Delphix strongly recommends that you regenerate this code and re-register the engine regularly to maximize the Support Security of the Delphix Engine. Delphix recommends doing this every six months.

## Summary

The final summary tab will enable you to review your configurations for System Time, Network, Storage, Serviceability, and Authentication.

1. Click the **Back** button to go back and to change the configuration for any of these server settings.
2. If you are ready to proceed, then click **Submit**.
3. Click **Yes** to confirm that you want to save the configuration.
4. Click **Setup** to acknowledge the successful configuration.
5. There will be a wait of several minutes as the Delphix Engine completes the configuration.

## SQL server source hosts and databases

### Source host requirements

Windows servers that will be added as Source Environments must meet the following requirements:

Source Host Requirement	Explanation
<p>To allow Delphix-initiated backups, the service account running each SQL Server instance (the Instance Owner) should be one of:</p> <ul style="list-style-type: none"> <li>• A domain user (e.g. MYDOMAIN\accountname ) (RECOMMENDED)</li> <li>• A Managed Service Account or Group Managed Service Account ( MYDOMAIN\accountname\$ ) (requires Windows 2012 and later, and SQL Server 2008R2 or later)</li> <li>• The LOCAL SYSTEM account ( NT AUTHORITY\SYSTEM )</li> <li>• The NETWORK SERVICE account ( NT AUTHORITY\NETWORK SERVICE )</li> </ul>	<p>Backups initiated by the Delphix Engine (Delphix Managed Backups or manual snapshots which request a backup) will fail if the Delphix Engine cannot map the Instance Owner to an Active Directory user or computer object.</p>
<p>The source host, proxy, and staging environments must have appropriate cross-domain trust relationships</p>	<p>For more information on these requirements, see the document <a href="#">Delphix in Multi-domain Windows Environments</a>.</p>

Recommended source Windows user requirement

Aligning to our zero-trust approach, “Delphix OS” user permissions on the Source can now be configured with the least privilege necessary from previous super-user “Backup Operator” requirements.

Recommended source Windows user requirement	Explanation
<p>Have the "Log on as batch" privilege on the source host</p>	<p>This permission is required for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).</p>
<p>Have read permission for “ Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\winreg ” on the source host</p>	<p>This permission is required to have access to the remote registry. Delphix uses this privilege to discover SQL Server instances and gather system details, using Windows remote registry access.</p>
<p>Be a member of the Users group on the Staging Host</p>	<p>In order to discover and query SQL Server instances as the Source Windows User, scripts are run on that user at the Staging Host.</p>

Recommended source Windows user requirement	Explanation
Have the "Log on as batch" privilege on the Staging host	This permission is required for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <i>Source Database Login Requirements</i> section below.

This recommended permission requires editing the registry on each Source host(s) so that membership of the Backup Operators group is not required. The Backup Operators group confers additional permissions that are not used by Delphix, such as being able to shut down the host.

#### Deprecated source Windows user requirements

Source Windows User Requirement	Explanation
Be a member of the Backup Operators group on the Source Host	Delphix uses this privilege to discover SQL Server instances and gather system details, using Windows remote registry access.
Be a member of the Users group on the Staging Host	In order to discover and query SQL Server instances as the Source Windows User, scripts are run on that user at the Staging Host.
Have the "Log on as batch" privilege on the Staging host	We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <i>Source Database Login Requirements</i> section below.

#### Source database login requirements

The Delphix Engine requires SQL Server logins to be created on each SQL Server instance that the Delphix Engine will communicate with:

- A database login for Environment discovery and monitoring, specified when Adding an Environment. This must be a Windows Authentication login for the Source Windows User configured in the previous section.
- A database login for dSource (Source Database) monitoring and interaction, specified when Linking a dSource. This user can be:
  - The same as the Source Windows User;
  - A different Windows Authentication login (this user must also have Log on as a Batch Job privileges on the Staging host); or
  - A SQL Authentication login

These users must have the following permissions on each instance:

Object	Privileges Required	dSource User	Environment User	Purpose
Server	CONNECT SQL	X	X	Access to the SQL Server instance
Database: master	db_datareader	X	X	Access to information about attached databases
Database: msdb	db_datareader	X		Access to the backup history
Each user database to be linked	PUBLIC	X		Delphix will periodically run queries to check the current size of the database
Each user database to be linked	db_backupoperator	X		<b>Optional:</b> Required for backups to be initiated by Delphix (using Delphix Managed Backups, or when Delphix initiates a backup during a manual Snapshot)
Server	VIEW ANY DEFINITION	X	X	<b>Optional:</b> Required for the discovery of databases in Availability Groups
Server	VIEW SERVER STATE	X	X	<b>Optional:</b> Required for the SnapSync and discovery of Availability Groups
Object: master.dbo.sqlutility	EXECUTE	X		<b>Optional:</b> Required when using backups created by Red Gate SQL Backup
Object: master.dbo.xp_sqlightspeed_version	EXECUTE	X		<b>Optional:</b> Required when using backups created by Quest LiteSpeed for SQL Server

## List of source tables accessed by the Delphix engine

Using the db\_datareader permission, the Delphix Engine accesses the following system tables in the master and msdb databases on the source host:

System table	Justification
master.sys.databases	Used to determine the name and recovery model of databases within discover SQL Server instances
master.sys.availability_groups	Used for discovering all the availability groups within an Availability Group source environment.
master.sys.availability_group_listeners	Used for discovering all the availability group listeners within an Availability Group source environment. <ul style="list-style-type: none"> <li>A requirement for dSource linking of SQL Server clustered databases (replicas) is to provide an AG (Availability Group) listener for AG cluster source discovery. This is implemented on AG cluster source discovery as a failsafe if AG cluster source database authentication configuration change down the line, ensuring the Delphix engine has a way to reach the cluster and continue certain operations.</li> </ul>
master.sys.availability_databases_cluster	Used for discovering all the availability group clusters within an Availability Group source environment.
master.sys.availability_replicas	Used for discovering all the availability group replicas within an Availability Group source environment.
master.sys.database_files	Used to determine the size of databases and whether filestream is enabled for a database
master.sys.dm_exec_requests	Used to enable Delphix to report backup operation progress
master.sys.master_files	Used to determine the primary file of a database
master.sys.filegroups	Used to determine the filegroups of a database so that Delphix can configure VDBs with the same filegroups
msdb.dbo.backupset	Used to determine new backups that have been taken. This table is regularly queried to find out if a new backup image has been taken and needs to be synchronized with Delphix.
msdb.dbo.backupmediafamily	Used to determine the physical device names of the backup files comprising a backup.

## SQL server staging hosts and databases

### Staging host requirements

Windows servers which will be added as Staging Environments must meet the following requirements:

Staging Host Requirement	Explanation
<p>The service account running each SQL Server instance (the Instance Owner) must be one of:</p> <ul style="list-style-type: none"> <li>• A domain user (e.g. <code>MYDOMAIN\accountname</code>) (RECOMMENDED)</li> <li>• A Managed Service Account or Group Managed Service Account ( <code>MYDOMAIN\accountname\$</code> ) (requires Windows 2012 and later, and SQL Server 2008R2 or later)</li> <li>• The LOCAL SYSTEM account ( <code>NT AUTHORITY\SYSTEM</code> )</li> <li>• The NETWORK SERVICE account ( <code>NT AUTHORITY\NETWORK SERVICE</code> )</li> </ul>	<p>Access to existing database backups for Snapshots and Validated Sync operations will fail if the service account cannot access backups created by the Source database instance.</p>
<p>The source host, proxy and staging environments must have appropriate cross-domain trust relationships</p>	<p>For more information on these requirements, see the document <a href="#">Delphix in Multi-domain Windows Environments</a>.</p>
<p>The edition of the installed SQL Server instance(s) must support all database features used by linked Source databases</p>	<p>SQL Server may raise an error during some dSource operations if the Staging SQL Server Instance does not support features used by the Source Database.</p> <p>This is most easily addressed by using the same edition of SQL Server as the Source database.</p> <p>Features in use on the Source database can be checked using the <code>sys.dm_db_persisted_sku_features</code> dynamic view.</p>
<p>Must have both the Source and Staging Windows Users configured as local Windows users</p>	<p>See the sections <i>Source Windows User Requirements</i> and <i>Staging Windows User Requirements</i> for more detail.</p>
<p>Delphix Connector software is installed and running</p>	<p>See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.</p>

Staging Host Requirement	Explanation
Recommended iSCSI Registry settings must be in place	<p>See <a href="#">Requirements for Windows iSCSI Configuration</a> and <a href="#">Knowledge Base Article KBA1251</a> for instructions on applying these settings*.</p> <p>*Please note that in 6.0.x, these performance settings are subject to change based on further tuning efforts by Delphix Engineering.</p>
sqlcmd command line utility must be installed on the servers hosting VDBs and staging databases. The utility should be in the Delphix operating system user's PATH environment variable.	Delphix does not run sqlcmd (or any other process) directly on the source SQL Server instance. It runs sqlcmd on the staging/connector host.

Staging Windows user requirements

The Delphix Engine needs a Windows domain user — for example, `MYDOMAIN\delphix_os` — to be specified when adding Staging environments to the Delphix Engine. This user must have the following permissions:

Staging User Requirement	Explanation
Be a member of the Windows "Local Administrators" group on the Staging Host	We require this permission for mounting iSCSI LUNs presented by the Delphix Engine to the staging and target hosts. Microsoft utilities used by the Delphix Engine, such as diskpart, <a href="#">require membership of this group</a> .
Have the "Log on as batch" privilege on the Staging host	We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to access existing backups from the Source Database	<p>If accessing existing native, Red Gate, or LiteSpeed backups, the following permissions are required:</p> <ul style="list-style-type: none"> <li>• The Staging Windows User and the service account running SQL Server must both have permission to access the database backups via SMB (Windows file sharing)</li> <li>• The Staging Windows User and the service account running SQL Server must both have NTFS Permissions to access the database backups</li> </ul> <p>Separate documents describe requirements if <a href="#">Linking a dSource from a NetBackup SQL Server Backup</a> or <a href="#">Linking a dSource from a Commvault SQL Server Backup</a>.</p>
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <i>Staging Database Login Requirements</i> section below.

### Staging database login requirements

The Delphix Engine requires a Windows Authentication login to be created for the Staging Windows User on each SQL Server instance that the Delphix Engine will communicate with, with the following permissions:

Object	Privileges Required	Delphix OS User (Windows Login)	Purpose
Server	CONNECT SQL	Y	Access to the SQL Server instance
Server	sysadmin	Y	<p>The staging and target databases are managed and administered completely by Delphix. Our functionality requires many administrative operations on those databases and requires full access to them.</p> <p>Since database ownership can be changed by customers as part of configuring virtual databases, we require the sysadmin role to continue to administer the databases.</p>

### SQL server target hosts and databases

#### Target host requirements

Windows servers which will be added as Target Environments must meet the following requirements:

Target Host Requirement	Explanation
Delphix Connector software is installed and running	See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.
Recommended iSCSI Registry settings must be in place	See <a href="#">Requirements for Windows iSCSI Configuration</a> and <a href="#">Knowledge Base Article KBA1251</a> for instructions on applying these settings.

Target Host Requirement	Explanation
The edition of the installed SQL Server instance(s) must support all database features used by linked Source databases	SQL Server may raise an error during some dSource operations if the Staging SQL Server Instance does not support features used by the Source Database.  This is most easily addressed by using the same edition of SQL Server as the Source database.  Features in use on the Source database can be checked using the <code>sys.dm_db_persisted_sku_features</code> dynamic view.
sqlcmd command line utility must be installed on the servers hosting VDBs and staging databases. The utility should be in the Delphix operating system user's PATH environment variable.	Delphix does not run sqlcmd (or any other process) directly on the source SQL Server instance. It runs sqlcmd on the staging/connector host.

#### Target Windows user requirements

The Delphix Engine needs a Windows domain user — for example, `MYDOMAIN\delphix_os` — to be specified when adding Target environments to the Delphix Engine. This user must have the following permissions:

Target User Requirement	Explanation
Be a member of the Windows "Local Administrators" group on the Target Host	We require this permission for mounting iSCSI LUNs presented by the Delphix Engine to the staging and target hosts. Microsoft utilities used by the Delphix Engine, such as diskpart, <a href="#">require membership of this group</a> .
Have the "Log on as batch" privilege on the Target Host	We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <i>Target Database Login Requirements</i> section below.
Delphix Connector software is installed and running	See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.

#### Target database login requirements

The Delphix Engine requires a Windows Authentication login to be created for the Target Windows User on each SQL Server instance that the Delphix Engine will communicate with, with the following permissions:

Object	Privileges Required	Delphix OS User (Windows Login)	Purpose
Server	CONNECT SQL	Y	Access to the SQL Server instance
Server	sysadmin	Y	<p>The staging and target databases are managed and administered completely by Delphix. Our functionality requires many administrative operations on those databases and requires full access to them.</p> <p>Since database ownership can be changed by customers as part of configuring virtual databases, we require the sysadmin role to continue to administer the databases.</p>

### Supported roles for failover cluster instances and always on availability groups

Failover Cluster Instances and Always On Availability groups cannot be used as Staging Environments, and VDBs cannot be provisioned into Availability Groups.

 When adding a Failover Cluster Instance or Always On Availability Group, all nodes of the cluster must meet the requirements described in this document.

The following table shows how different SQL Server instance types should be added from the Add Environment screen:

Instance Type	Added As	Environment Role		
		Source Environment	Staging Environment	Target Environment
Standalone Instance	Standalone	Y*	Y	Y
Failover Cluster Instance (FCI)	Standalone	Y*	N	N
Failover Cluster Instance (FCI)	Cluster	N	N	Y
Always On Availability Group (AG)	Cluster	Y	N	N**

\* Databases that are participating in Availability Groups will not be discovered during the discovery of a Standalone environment.

\*\* VDBs cannot be provisioned into availability groups. However, SQL Server instances that participate in an Availability Group can also be added as Standalone Instances.

#### Using a Failover Cluster Instance as both Source and Target

A Failover Cluster Instance added as an environment once (as either a Source or Target environment) cannot be used as both a Source and Target.

If this is required, the environment can be added twice:

- Once as a Standalone Source environment
- Once as a Cluster Target environment

The Standalone Source environment can be used for linking dSources, and the Cluster Target environment is used for provisioning VDBs.

As suggested by the Best Practice note earlier in this article, this is not a recommended configuration. Where possible, SQL Server failover cluster instances that the Delphix Engine will use as a target should not be used to host databases other than Delphix VDBs.

#### Requirements for failover cluster target environments

The following additional requirements exist for Windows Failover Cluster Instances added as Target Environments, to be used for VDB Provisioning.

- You must first add each node in the Windows Failover Cluster individually as a standalone target environment, using a non-clustered address. See [Adding a SQL Server Standalone Target Environment](#).
  - The Delphix Engine may show a warning that it cannot discover the Failover Cluster Instances on each standalone host. This is expected.
- Each clustered SQL Server instance must have at least one clustered disk added to the clustered instance resource group, which can be used for creating mount points to Delphix storage.
  - The clustered drive must have a drive letter assigned to it.
  - The clustered drive must be formatted using the "GUID Partition Table (GPT)" partition style, in order for the Delphix Engine to automatically discover the drive letter as a valid option for the cluster instance. An MBR-formatted disk requires manual verification outside of Delphix that the disk has been correctly added to the MSSQL clustered resource group prior to creating the VDB. When provisioning the VDB, you must manually specify the desired MBR disk, because it will not appear in the Delphix GUI.
  - The clustered drive must be added to the clustered instance resource group as a dependency in the Failover Cluster Manager.
- Each node in the cluster must have the Failover Cluster Module for Windows PowerShell feature installed.
  - While running Windows PowerShell as an administrator, enter this command to test that the module is available: `Import-Module FailoverClusters`
- An additional target environment that can be used as a Connector Environment must exist.
  - This environment must **not** be a node in the cluster.
  - This environment should be part of the same Active Directory domain as the cluster.

#### Add the SQL server source environment

Delphix does not require running the Connector on your source. Instead, you'll use the Validated Sync environment as a connector environment to discover the source by proxy.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.

4. Next to **Environments**, click the **Actions** menu, and select **Add Environment**.
5. In the **Add Environment** wizard, Host and Server tab select:
  - a. Host OS: **Windows**
  - b. Host Type: **Source**
  - c. Server Type:
  - d. If you are adding a Windows Server Failover Cluster (WSFC), add the environment based on which WSFC feature the source databases use:
    - Failover Cluster Instances Add the environment as a **standalone** source using the **cluster name** or **address**.
    - AlwaysOn Availability Groups Add the environment as a **cluster** source using the **cluster name** or **address**.
  - e. Otherwise, add the environment as a **standalone** source.
6. Click **Next**.
7. In the Environment Settings tab select a **Connector Environment**. Connector environments are used as a proxy for running discovery on the source. If no connector environments are available for selection, you will need to set them up as described in [Adding a SQL Server Standalone Target Environment](#). Connector environments must:
  - have the Delphix Connector installed
  - be registered with the Delphix Engine from the host machine where they are located.
8. Enter the **Environment Name**, **Node Address**, **OSUsername**, and **OSPassword** for the source environment.
9. Click **Submit**.

As the new environment is added, you will see multiple jobs running in the Delphix Admin Job History to Create and Discover an environment. In addition, if you are adding a cluster environment, you will see jobs to Create and Discover each node in the cluster and their corresponding hosts. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel. If you don't see it, click the **Actions** menu and select **Refresh All**.

## Linking a SQL server data source (dSource)

Linking a dSource will ingest data from the source and create a dSource object on the engine. The dSource is an object that the Delphix Virtualization Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools.

For an overview of all dSource related actions, please [Managing Data Sources and Syncing Data](#).

When linking a dSource from a SQL Server source database, Delphix offers several different methods of capturing backup information:

- SQL Server Managed Backups, where the SQL Server source database schedules and initiates backups and the Delphix Engine captures them
  - Full backups
  - Full or differential backups
  - Transaction log backups (with LogSync disabled)
  - Transaction log backups (with LogSync enabled)
- Delphix Managed Backups, where the Delphix Engine schedules and initiates the backups from the source database, and captures them

## Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Click the plus icon and select **Add dSource**.
4. In the **Add dSource** wizard, select the source database with the correct environment user-specified.

5. Select user type for source database authentication and enter the login credentials. Enter username and password for Database user or Domain (Windows) user. For Environment User, select a source environment user from the dropdown list and click **Next**.
6. Enter a name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. Select the **Data Management** settings needed. For more information, [Data Management Settings for SQL Server Data Sources](#).
8. Select the Staging environment and SQL Instance that will be used to manage the staging database used for validated sync of the dSource.
9. Select any policies for the new dSource.
10. Enter any scripts that should be run on the **Hooks** page.
11. Review the dSource Configuration and Data Management information, and then click **Submit**.

### Provisioning a SQL server virtual database (VDB)

1. Login to the **Delphix Management** application.
2. Select **Manage > Datasets**.
3. Select a **dSource**.
4. Click **Timeflow** tab.
5. Next to a snapshot select the  Provision VDB icon. The **Provision VDB** panel will open, and the **Database Name** and **Recovery Model** will auto-populate with information from the dSource.
6. Select a **target environment**.
7. Select an **Instance** to use.
8. If the selected target environment is a Windows Failover Cluster environment, select a drive letter from **Available Drives**. This drive will contain volume mount points to Delphix storage. **Note** : Windows Cluster Volume Management Software Requirements  
Only cluster volumes managed by the native Windows Volume Manager are supported. For example, cluster volumes managed by Veritas VxVM are not supported.  
If you use third-party volume management software, create a new LU (recommended to be 10GB in size) and add this LU as a clustered resource to the SQL Server instance using native Windows volume management tools. Assign a drive letter for this LU. You can then use this LU as the volume mount point location for Delphix VDB provisioning
9. Enter a **VDB Name** and select a **Target Group** for the VDB.
10. Enable **Auto VDB Restart** to allow the Delphix Engine to automatically restart the VDB when it detects target host reboot.
11. Click **Next**.
12. Select a **Snapshot Policy** for the VDB. Click **Next**.
13. Specify any **Pre-** or **Post-Scripts** that should be used during the provisioning process.
14. Click **Next**.
15. The final summary tab will enable you to review your configurations.
16. Click **Submit**.

When provisioning starts, the VDB will appear in the **Datasets** panel. Select the VDB and navigate to the **Status** tab to see the progress of the job. When provisioning is complete, you can see more information on the **Configuration** tab.

**i** You can select a SQL Server instance that has a higher version than the source database and the VDB will be automatically upgraded. For more information about compatibility between different versions of SQL Server, see [SQL Server Support Matrix](#).

## Provisioning by snapshot or logSync

When provisioning by snapshot, you can provision to the start of any particular snapshot, either by time or LSN.

 You can take a new snapshot of the dSource and provision from it by clicking the **Camera** icon.

Provisioning By Snapshot	Description
Provision by Time	You can provision to the start of any snapshot by selecting that snapshot card from the <b>TimeFlow</b> tab, or by selecting the time icon and entering a value in the time entry fields. The values you enter will snap to the beginning of the nearest snapshot.
Provision by LSN	You can use <b>Provision by LSN</b> control to open the LSN entry field. Here, you can type or paste in the LSN to which you want to provision. After entering a value, it will "snap" to the start of the closest appropriate snapshot. Provisioning a SQL Server VDB Procedure

## Next steps

Congratulations! You have provisioned your first virtual database!

Now, perform some simple functional tests with your application. You can connect your app to the VDB using standard TNS/JDBC techniques. Delphix has already registered the VDB for you on the target listener.

We suggest the following next steps:

1. Drop a table and use the VDB Rewind feature to test the recovery of your VDB.
2. Take a snapshot of your dSource and refresh your VDB to quickly get fresh production data.
3. Provision a new VDB from your VDB to test sharing data quickly with other teams.
4. Mask your new VDB to protect sensitive data. Provision new VDBs from that masked VDB to quickly provide safe data to the development and QA teams.

## SQL Server support and requirements

This section covers the following topics:

- [SQL Server support matrix](#)
- [Overview of requirements for SQL Server environments](#)
- [Requirements for Windows iSCSI configuration](#)
- [Network access requirements for SQL Server](#)

## SQL Server support matrix

**Key:**

Color	Supported?
Y	Yes
NA	Not Applicable

### Windows server

Supported OS version	Supported DBMS version					
	SQL Server 2012	SQL Server 2014	SQL Server 2016	SQL Server 2017	SQL Server 2019	SQL Server 2022
Windows Server 2012	Y	Y	Y	Y	NA	NA
Windows Server 2012 R2	Y	Y	Y	Y	NA	NA
Windows Server 2016	Y	Y	Y	Y	Y	Y
Windows Server 2019	NA	NA	Y	Y	Y	Y
Windows Server 2022	NA	NA	NA	Y	Y	Y

#### Windows support

Delphix supports both "Windows with Desktop Experience" and Windows Core (Windows without Desktop Experience) server installations.

#### Windows support

After applying Windows updates or .NET updates for Windows Server 2016 or 2019, servers used to host Delphix VDBs may experience the following symptoms:

- CPU usage on the Windows target host may increase significantly, possibly reaching 100%.
- PowerShell may take up to 10 seconds to launch from the command line.

For more information on how to resolve this issue, see [KBA6024](#)

#### **64-bit Windows only**

Delphix supports only 64-bit versions of Windows on VDB Target Hosts and Staging Target Hosts. This restriction does not apply to Source Hosts.

#### **Check OS compatibility**

The Windows Server OS versions on the Staging Target Hosts and VDB Target Hosts must be compatible. Please refer to the compatibility matrices below.

#### **SQL server failover clusters**

There are additional restrictions on supported Windows and SQL Server versions for SQL Server Failover Cluster target environments.

For details, see [Adding a SQL Server Failover Cluster Target Environment](#)

### Supported SQL versions

SQL server version	Delphix version
SQL Server 2012 (11.0)	Delphix 3.1.2 and beyond
SQL Server 2014 (12.0)	Delphix 4.1.3 and beyond
SQL Server 2016 (13.0)	Delphix 5.1.4 and beyond
SQL Server 2017 (14.0)	Delphix 5.2.3 and beyond
SQL Server 2019 (15.0)	Delphix 5.3.7 and beyond
SQL Server 2022 (16.0)	Delphix 8.0.0 and beyond

### Supported SQL server editions

- Standard
- Enterprise

#### **SQL server editions**

For Staging Target Hosts, you can use SQL Server Standard Edition only if the source databases do not use SQL Server Enterprise Edition specific features, such as partitioned tables.

However, it is important for VDB target hosts to use the same edition of SQL Server software as the source database so that all features available in the source are also available in the VDB.

### Supported windows connector versions

You can always download the current Windows connector version from the Delphix Engine from the following locations:

Delphix Dynamic Data Platform versions before 6.0.5.0:

```
http://<name of your Delphix Engine>/connector/DelphixConnectorInstaller.msi
```

Delphix Dynamic Data Platform versions 6.0.5.0 onwards:

```
http://<name of your Delphix Engine>/connector/DelphixConnectorInstaller.exe
```

The Delphix Connector and Engine are generally backward-compatible.

Delphix connector version 1.18.0 and beyond is compatible with Delphix Engine 6.0.5.0 and later releases.

Delphix connector version 1.17.0 or earlier is compatible with Delphix Engine 6.0.4.0 and earlier releases

### Checking the windows connector version

After installing the connector, you can perform the following steps to determine the Windows connector version.

1. Navigate to the Windows Environment.
2. In the search box on the taskbar, type Add or Remove Programs or launch **Start > ControlPanel > Programs > Programs and Features**.
3. On the Add or Remove Programs screen, locate Delphix Connector and then click on the software to check the version installed.

### Windows connector matrix

The following table details the supported Windows Connector and JRE versions for the corresponding Delphix Dynamic Data Platform versions.

Delphix dynamic data platform version	Windows connector version	JRE version
4.2	1.2.0	1.7.0_71 (4.2.5.1)
4.3	1.3.0	1.8.0_40 (4.3.5.1)
5.1.0.0-5.1.4.0	1.4.0	1.8.0_40
5.1.5.0-5.1.9.0	1.5.0	1.8.0_112
5.2.0.0-5.2.2.0	1.9.0	1.8.0_131 (5.2.2.1)

<b>Delphix dynamic data platform version</b>	<b>Windows connector version</b>	<b>JRE version</b>
5.2.3.0-5.2.4.0	1.10.0	1.8.0_162
5.2.5.0-5.3.3.0	1.12.0	1.8.0_202
5.3.4.0	1.13.0	1.8.0_202
5.3.5.0	1.14.0	1.8.0_202
5.3.6.0-5.3.7.0	1.15.0	1.8.0_202
5.3.8.0-6.0.0.0	1.16.0	1.8.0_202
6.0.1.0-6.0.4.0	1.17.0	OpenJDK 8u242
6.0.5.0-6.0.8.0	1.18.0	OpenJDK 8u262-b10
6.0.9.0-6.0.10.0	1.20.0	OpenJDK 8u282-b08
6.0.11.0	1.21.0.0	OpenJDK 8u302-b08
6.0.12.0	1.22.0.0	OpenJDK 8u302-b08
6.0.12.1	1.22.0.0	OpenJDK 8u302-b08
6.0.13.0	1.23.0.0	OpenJDK 8u302-b08
6.0.13.1	1.23.0.0	OpenJDK 8u302-b08
6.0.14.0	1.23.0.0	OpenJDK 8u302-b08
6.0.15.0	1.24.0.0	OpenJDK8u332-b09
6.0.16.0	1.24.0.0	OpenJDK8u332-b09
6.0.17.0	1.27.0.0	OpenJDK 8u345-b01
7.0.0.0	1.27.0.0	OpenJDK 8u345-b01

Delphix dynamic data platform version	Windows connector version	JRE version
8.0.0.0	1.27.0.0	OpenJDK 8u345-b01
9.0.0.0	1.28.0.0	OpenJDK 8u362-b09
10.0.0.0	1.29.0.0	OpenJDK 8u362-b09

The following table details the .Net connector version compatibility for the corresponding Windows Connector versions.

.Net connector version	Windows connector version
3.5	1.17.0 and earlier
3.5 and 4.0+	1.18.0 and higher

File checksum / hashes

The following table provides the MD5 and SHA256 file hash for recent Delphix versions, in the instance that a security policy requires an exception for software installation.

Delphix dynamic data platform version	Connector version	MD5 Hash	SHA256 Hash
6.0.0.0	1.16.0	84616c4f86c0d871127feb26b9b8bd52	bc2e5e4b26c33d739f7be12f53637979481e1371325e0b5c7645462f6cf5f4f3

### Source environment operating system compatibility

Source environments can be running any supported Windows operating system version. There are no compatibility requirements between the source environment's operating system and that of the target environments. For more information, see [Overview of Setting Up SQL Server Environments](#)

### Staging and target environment operating system version compatibility

The operating system version on the target environment that will contain the virtual databases must be equal to or higher than that on the staging target.

### Source and staging environment SQL server version compatibility

The SQL Server version on the staging environment must be equal to that on the source environment.

#### **Provisioning to higher SQL versions when the source is SQL server 2005**

For SQL Server 2005, direct provisioning to higher SQL Server versions is only supported for provisioning to SQL Server 2012 or higher. You can first provision a VDB to SQL Server 2005 and then upgrade it to a higher version by following the steps outlined in [Upgrading SQL Server VDBs](#)

### Supported SQL server backup software

Delphix currently supports the following software for dSource backups:

- SQL Server native backups - all formats, including but not limited to
  - Striped
  - Compressed
  - Append
  - Overwrite
- Veritas NetBackup
  - Delphix currently supports NetBackup v7.7.3, v8.0, and v8.1.
  - The version of the NetBackup client on the staging environment must be the same as that on the source.
  - If the dSource is backed up with NetBackup, the source and staging environments must have a NetBackup client installed. VDB target environments do not need to have NetBackup installed.
  - Logsync (point-in-time provision) is currently not supported.
  - See [Linking a dSource from a NetBackup SQL Server Backup](#) for more NetBackup requirements and additional information about NetBackup.
- Commvault
  - Delphix currently supports Commvault v11.
  - The version of Commvault SQL Agent on the staging environment must be the same as that on the source.
  - If the dSource is backed up with Commvault, the source and staging environment must have Commvault SQL Agent installed. VDB target environments do not need to have Commvault SQL Agent installed.
  - Commvault SQL Agent on staging environment must be registered to the CommServe server, which is managing source database backups.
  - Logsync (point-in-time provision) is currently not supported.
  - See [Linking a dSource from a Commvault SQL Server Backup](#) for more Commvault requirements and additional information about Commvault.
- Quest/NetVault LiteSpeed
  - Delphix currently supports LiteSpeed v5.0.0.0 to v8.9.

- The LiteSpeed version on the staging environment must be the same or higher than that on the source.
- If the dSource is backed up with LiteSpeed, the source and the staging environments must also have LiteSpeed installed.  
VDB target environments do not need to have LiteSpeed installed.
- On source SQL Server Instance, the dSource user must be granted execute privilege on extended stored procedure master.dbo.xp\_sqlightspeed\_version.
- Red Gate SQL Backup Pro
  - Delphix currently supports SQL Backup Pro v7.3 to v7.6 and v10.0.
  - The version of SQL Backup Pro on the staging environment must be the same as that on the source.
  - On source SQL Server Instance, the dSource database user must be granted execute privilege on extended stored procedure master.dbo.sqbutility.

If the dSource is backed up with SQL Backup Pro, the source and the staging environments must have SQL Backup Pro installed.

VDB target environments do not need to have SQL Backup Pro.

Source and provisioning environment SQL server compatibility matrix

When provisioning a VDB, the SQL Server version on the target should be equal to or higher than that on the source.

	Provisioning target environment					
	SQL Server 2012	SQL Server 2014	SQL Server 2016	SQL Server 2017	SQL Server 2019	SQL Server 2022
<b>Source Environment</b>						
<b>SQL Server 2012</b>	X	X	X	X	X	X
<b>SQL Server 2014</b>		X	X	X	X	X
<b>SQL Server 2016</b>			X	X	X	X
<b>SQL Server 2017</b>				X	X	X
<b>SQL Server 2019</b>					X	X
<b>SQL Server 2022</b>						X

## Overview of requirements for SQL Server environments

### SQL Server staging hosts and databases

This document identifies the requirements for interactions between the Delphix Engine and SQL Server environments and outlines the set of system tables to which we currently require access.

### Delphix SQL Server architectural diagram - Traditional pull architecture

This diagram depicts the environments and hosts with which the Delphix Engine interacts. Each type of environment has different requirements, which are described below.

### Delphix SQL Server architectural diagram - Staging push architecture

This diagram depicts the Staging and target hosts with which the Delphix Engine interacts. Note that the Delphix Engine does not interact with the Source Database. For more details on the Staging Push mechanism, see [Staging Push Mechanism with SQL Server](#) and [Staging Push Implementation for SQL Server](#).

SQL server source hosts and databases

Source host requirements

Windows servers that will be added as Source Environments must meet the following requirements:

Source Host Requirement	Explanation
<p>To allow Delphix-initiated backups, the service account running each SQL Server instance (the Instance Owner) should be one of:</p> <ul style="list-style-type: none"> <li>• A domain user (e.g. MYDOMAIN\accountname ) (RECOMMENDED)</li> <li>• A Managed Service Account or Group Managed Service Account ( MYDOMAIN\accountnameundefined ) (requires Windows 2012 and later, and SQL Server 2008R2 or later)</li> <li>• The LOCAL SYSTEM account ( NT AUTHORITY\SYSTEM )</li> <li>• The NETWORK SERVICE account ( NT AUTHORITY\NETWORK SERVICE )</li> </ul>	<p>Backups initiated by the Delphix Engine (Delphix Managed Backups or manual snapshots which request a backup) will fail if the service account cannot access backups created by the Source database instance</p>
<p>The source host, proxy and staging environments must have appropriate cross-domain trust relationships</p>	<p>For more information on these requirements, see the document <a href="#">Delphix in Multi-domain Windows Environments.</a></p>

Recommended source Windows user requirements

Aligning to our zero-trust approach, “Delphix OS” user permissions on the Source can now be configured with the least privilege necessary from previous super-user “Backup Operator” requirements.

Recommended Source Windows User Requirements	Explanation
<p>Have the "Log on as batch" privilege on the source host</p>	<p>This permission is required for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on</p>
<p>Have read permission for "Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurePipeServers\winreg" on the source host</p>	<p>This permission is required to have access to the remote registry. Delphix uses this privilege to discover SQL Server instances and gather system details, using Windows remote registry access.</p>

Recommended Source Windows User Requirements	Explanation
Be a member of the Users group on the Staging Host	In order to discover and query SQL Server instances as the Source Windows User, scripts are run on that user at the Staging Host.
Have the "Log on as batch" privilege on the Staging host	This permission is required for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <a href="#">Source Database Login Requirements</a> section below.

This recommended permission requires editing the registry on each Source host(s) so that membership of the Backup Operators group is not required. The Backup Operators group confers additional permissions that are not used by Delphix, such as being able to shut down the host.

#### Deprecated source Windows user requirements

Source Windows User Requirement	Explanation
Be a member of the Backup Operators group on the Source Host	Delphix uses this privilege to discover SQL Server instances and gather system details, using Windows remote registry access.
Be a member of the Users group on the Staging Host	In order to discover and query SQL Server instances as the Source Windows User, scripts are run on that user at the Staging Host.
Have the "Log on as batch" privilege on the Staging host	We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <a href="#">Source Database Login Requirements</a> section below.

#### Source database login requirements

The Delphix Engine requires SQL Server logins to be created on each SQL Server instance that the Delphix Engine will communicate with:

- A database login for Environment discovery and monitoring, specified when Adding an Environment. This must be a Windows Authentication login for the Source Windows User configured in the previous section.
- A database login for dSource (Source Database) monitoring and interaction, specified when Linking a dSource. This user can be:

- The same as the Source Windows User;
- A different Windows Authentication login (this user must also have Log on as a Batch Job privileges on the Staging host); or
- A SQL Authentication login

These users must have the following permissions on each instance:

Object	Privileges Required	dSource User	Environment User	Purpose
Server	CONNECT SQL	Y	Y	Access to the SQL Server instance
Database: master	db_data reader	Y	Y	Access to information about attached databases
Database: msdb	db_data reader	Y		Access to the backup history
Each user database to be linked	PUBLIC	Y		Delphix will periodically run queries to check the current size of the database
Each user database to be linked	db_back upoperat or	Y		Optional: Required for backups to be initiated by Delphix (using Delphix Managed Backups, or when Delphix initiates a backup during a manual Snapshot)
Server	VIEW ANY DEFINITI ON	Y	Y	Optional: Required for the discovery of databases in Availability Groups
Server	VIEW SERVER STATE	Y	Y	Optional: Required for the SnapSync and discovery of Availability Groups
Object: master.dbo.s qutility	EXECUTE	Y		Optional: Required when using backups created by Red Gate SQL Backup

Object	Privileges Required	dSource User	Environment User	Purpose
Object: master.dbo.xp_sqliightspeed_version	EXECUTE	Y		Optional: Required when using backups created by Quest LiteSpeed for SQL Server

List of source tables accessed by the Delphix engine

Using the db\_datareader permission, the Delphix Engine accesses the following system tables in the master and msdb databases on the source host:

System table	Justification
master.sys.databases	Used to determine the name and recovery model of databases within discover SQL Server instances
master.sys.availability_groups	Used for discovering all the availability groups within an Availability Group source environment.
master.sys.availability_group_listeners	Used for discovering all the availability group listeners within an Availability Group source environment. <ul style="list-style-type: none"> <li>• A requirement for dSource linking of SQL Server clustered databases (replicas) is to provide an AG (Availability Group) listener for AG cluster source discovery. This is implemented on AG cluster source discovery as a failsafe if AG cluster source database authentication configuration change down the line, ensuring the Delphix engine has a way to reach the cluster and continue certain operations.</li> </ul>
master.sys.availability_databases_cluster	Used for discovering all the availability group clusters within an Availability Group source environment.
master.sys.availability_replicas	Used for discovering all the availability group replicas within an Availability Group source environment.
master.sys.database_files	Used to determine the size of databases and whether filestream is enabled for a database
master.sys.dm_exec_requests	Used to enable Delphix to report backup operation progress
master.sys.master_files	Used to determine the primary file of a database

System table	Justification
master.sys.filegroups	Used to determine the filegroups of a database so that Delphix can configure VDBs with the same filegroups
msdb.dbo.backupset	Used to determine new backups that have been taken. This table is regularly queried to find out if a new backup image has been taken and needs to be synchronized with Delphix.
msdb.dbo.backupmediafamily	Used to determine the physical device names of the backup files comprising a backup.

### SQL server staging hosts and databases

#### Staging host requirements

Windows servers which will be added as Staging Environments must meet the following requirements:

Staging Host Requirement	Explanation
<p>The service account running each SQL Server instance (the Instance Owner) must be one of:</p> <ul style="list-style-type: none"> <li>• A domain user (e.g. <code>MYDOMAIN\accountname</code>) (RECOMMENDED)</li> <li>• A Managed Service Account or Group Managed Service Account (<code>MYDOMAIN\accountname\$</code>) (requires Windows 2012 and later, and SQL Server 2008R2 or later)</li> <li>• The LOCAL SYSTEM account (<code>NT AUTHORITY\SYSTEM</code>)</li> <li>• The NETWORK SERVICE account (<code>NT AUTHORITY\NETWORK SERVICE</code>)</li> </ul>	<p>Access to existing database backups for Snapshots and Validated Sync operations will fail if the service account cannot access backups created by the Source database instance.</p>
<p>The source host, proxy and staging environments must have appropriate cross-domain trust relationships</p>	<p>For more information on these requirements, see the document <a href="#">Delphix in Multi-domain Windows Environments</a>.</p>

Staging Host Requirement	Explanation
<p>The edition of the installed SQL Server instance(s) must support all database features used by linked Source databases</p>	<p>SQL Server may raise an error during some dSource operations if the Staging SQL Server Instance does not support features used by the Source Database.</p> <p>This is most easily addressed by using the same edition of SQL Server as the Source database.</p> <p>Features in use on the Source database can be checked using the <code>sys.dm_db_persisted_sku_features</code> dynamic view.</p>
<p>Must have both the Source and Staging Windows Users configured as local Windows users</p>	<p>See the sections <i>Source Windows User Requirements</i> and <i>Staging Windows User Requirements</i> for more detail.</p>
<p>Delphix Connector software is installed and running</p>	<p>See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.</p>
<p>Recommended iSCSI Registry settings must be in place</p>	<p>See <a href="#">Requirements for Windows iSCSI Configuration</a> and <a href="#">Knowledge Base Article KBA1251</a> for instructions on applying these settings*.</p> <p>*Please note that in 6.0.x, these performance settings are subject to change based on further tuning efforts by Delphix Engineering.</p>
<p>sqlcmd command line utility must be installed on the servers hosting VDBs and staging databases. The utility should be in the Delphix operating system user's PATH environment variable.</p>	<p>Delphix does not run sqlcmd (or any other process) directly on the source SQL Server instance. It runs sqlcmd on the staging/connector host.</p>

### Staging Windows user requirements

The Delphix Engine needs a Windows domain user — for example, `MYDOMAIN\delphix_os` — to be specified when adding Staging environments to the Delphix Engine. This user must have the following permissions:

Staging User Requirement	Explanation
<p>Be a member of the Windows "Local Administrators" group on the Staging Host</p>	<p>We require this permission for mounting iSCSI LUNs presented by the Delphix Engine to the staging and target hosts. Microsoft utilities used by the Delphix Engine, such as diskpart, <a href="#">require membership of this group</a>.</p>
<p>Have the "Log on as batch" privilege on the Staging host</p>	<p>We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).</p>

Staging User Requirement	Explanation
Be able to access existing backups from the Source Database	<p>If accessing existing native, Red Gate, or LiteSpeed backups, the following permissions are required:</p> <ul style="list-style-type: none"> <li>The Staging Windows User and the service account running SQL Server must both have permission to access the database backups via SMB (Windows file sharing)</li> <li>The Staging Windows User and the service account running SQL Server must both have NTFS Permissions to access the database backups</li> </ul> <p>Separate documents describe requirements if <a href="#">Linking a dSource from a NetBackup SQL Server Backup</a> or <a href="#">Linking a dSource from a Commvault SQL Server Backup</a>.</p>
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	<p>These requirements are described in the <a href="#">Staging Database Login Requirements</a> section below.</p>

### Staging database login requirements

The Delphix Engine requires a Windows Authentication login to be created for the Staging Windows User on each SQL Server instance that the Delphix Engine will communicate with, with the following permissions:

Object	Privileges Required	Delphix OS User (Windows Login)	Purpose
Server	CONNECT SQL	Y	Access to the SQL Server instance
Server	sysadmin	Y	<p>The staging and target databases are managed and administered completely by Delphix. Our functionality requires many administrative operations on those databases and requires full access to them.</p> <p>Since database ownership can be changed by customers as part of configuring virtual databases, we require the sysadmin role to continue to administer the databases.</p>

### SQL server target hosts and databases

#### Target host requirements

Windows servers which will be added as Target Environments must meet the following requirements:

Target Host Requirement	Explanation
Delphix Connector software is installed and running	See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.
Recommended iSCSI Registry settings must be in place	See <a href="#">Requirements for Windows iSCSI Configuration</a> and <a href="#">Knowledge Base Article KBA1251</a> for instructions on applying these settings.
The edition of the installed SQL Server instance(s) must support all database features used by linked Source databases	SQL Server may raise an error during some dSource operations if the Staging SQL Server Instance does not support features used by the Source Database.  This is most easily addressed by using the same edition of SQL Server as the Source database.  Features in use on the Source database can be checked using the <code>sys.dm_db_persisted_sku_features</code> dynamic view.
sqlcmd command line utility must be installed on the servers hosting VDBs and staging databases. The utility should be in the Delphix operating system user's PATH environment variable.	Delphix does not run sqlcmd (or any other process) directly on the source SQL Server instance. It runs sqlcmd on the staging/connector host.

Target Windows user requirements

The Delphix Engine needs a Windows domain user — for example, `MYDOMAIN\delphix_os` — to be specified when adding Target environments to the Delphix Engine. This user must have the following permissions:

Target User Requirement	Explanation
Be a member of the Windows "Local Administrators" group on the Target Host	We require this permission for mounting iSCSI LUNs presented by the Delphix Engine to the staging and target hosts. Microsoft utilities used by the Delphix Engine, such as diskpart, <a href="#">require membership of this group</a> .
Have the "Log on as batch" privilege on the Target Host	We require this permission for remote PowerShell execution. This privilege can be assigned through the Local Security Policy (Local Policies → User Rights Assignment → Log on as batch job).
Be able to login to each SQL Server instance that the Delphix Engine will communicate with	These requirements are described in the <i>Target Database Login Requirements</i> section below.
Delphix Connector software is installed and running	See <a href="#">Installing the Delphix Connector Service on the Target Database Servers</a> for instructions on installing the Delphix Connector.

Target database login requirements

The Delphix Engine requires a Windows Authentication login to be created for the Target Windows User on each SQL Server instance that the Delphix Engine will communicate with, with the following permissions:

Object	Privileges Required	Delphix OS User (Windows Login)	Purpose
Server	CONNECT SQL	Y	Access to the SQL Server instance
Server	sysadmin	Y	<p>The staging and target databases are managed and administered completely by Delphix. Our functionality requires many administrative operations on those databases and requires full access to them.</p> <p>Since database ownership can be changed by customers as part of configuring virtual databases, we require the sysadmin role to continue to administer the databases.</p>

Supported Roles for Failover Cluster Instances and Always On Availability Groups

Failover Cluster Instances and Always On Availability groups cannot be used as Staging Environments, and VDBs cannot be provisioned into Availability Groups.

 When adding a Failover Cluster Instance or Always On Availability Group, all nodes of the cluster must meet the requirements described in this document.

The following table shows how different SQL Server instance types should be added from the Add Environment screen:

Color		Supported?		
Y		Yes		
N		No		
		Environment Role		
Instance Type	Added As	Source Environment	Staging Environment	Target Environment
Standalone Instance	Standalone	Y*	Y	Y
Failover Cluster Instance (FCI)	Standalone	Y*	N	N

		Environment Role		
Failover Cluster Instance (FCI)	Cluster	N	N	Y
Always On Availability Group (AG)	Cluster	Supported	N	N **

\* Databases that are participating in Availability Groups will not be discovered during the discovery of a Standalone environment.

\*\* VDBs cannot be provisioned into availability groups. However, SQL Server instances that participate in an Availability Group can also be added as Standalone Instances.

#### Using a Failover Cluster Instance as both Source and Target

A Failover Cluster Instance added as an environment once (as either a Source or Target environment) cannot be used as both a Source and Target.

If this is required, the environment can be added twice:

- Once as a Standalone Source environment
- Once as a Cluster Target environment

The Standalone Source environment can be used for linking dSources, and the Cluster Target environment is used for provisioning VDBs.

As suggested by the Best Practice note earlier in this article, this is not a recommended configuration. Where possible, SQL Server failover cluster instances that the Delphix Engine will use as a target should not be used to host databases other than Delphix VDBs.

#### Requirements for failover cluster target environments

The following additional requirements exist for Windows Failover Cluster Instances added as Target Environments, to be used for VDB Provisioning.

- You must first add each node in the Windows Failover Cluster individually as a standalone target environment, using a non-clustered address. See [Adding a SQL Server Standalone Target Environment](#).
  - The Delphix Engine may show a warning that it cannot discover the Failover Cluster Instances on each standalone host. This is expected.
- Each clustered SQL Server instance must have at least one clustered disk added to the clustered instance resource group, which can be used for creating mount points to Delphix storage.
  - The clustered drive must have a drive letter assigned to it.
  - The clustered drive must be formatted using the "GUID Partition Table (GPT)" partition style, in order for the Delphix Engine to automatically discover the drive letter as a valid option for the cluster instance. An MBR-formatted disk requires manual verification outside of Delphix that the disk has been correctly added to the MSSQL clustered resource group prior to creating the VDB. When provisioning the VDB, you must manually specify the desired MBR disk, because it will not appear in the Delphix GUI.
  - The clustered drive must be added to the clustered instance resource group as a dependency in the Failover Cluster Manager.
- Each node in the cluster must have the Failover Cluster Module for Windows PowerShell feature installed.

- While running Windows PowerShell as an administrator, enter this command to test that the module is available: `Import-Module FailoverClusters`
- An additional target environment that can be used as a Connector Environment must exist.
  - This environment must **not** be a node in the cluster.
  - This environment should be part of the same Active Directory domain as the cluster.

Additional requirements for azure SQL server availability groups

Microsoft's [tutorial](#) and deployment template for building a *SQL Server AlwaysOn Cluster in Azure* does not include the full range of network connectivity that is available in on-premise deployments.

In addition to the connectivity provided by this template:

- The Staging Server must be able to connect to the **Cluster IP Address** using the RPC / Remote Registry port **TCP 445**; and
- The Availability Group Listener must be configured with a TCP Port, such as the SQL Server default 1433

Connectivity to the Cluster IP Address can be tested using the following PowerShell command. This command should be run from the Staging Server, and specify the Cluster Hostname:

```
New-Object System.Net.Sockets.TcpClient("aodns-fc.mydomain.local", "445")
```

 For Azure clusters, Delphix does not support DNN (Distributed Network Name) at the WSFC level. However, DNN (Distributed Network Name) is supported for creating a SQL AG listener in SQL clustering.

To allow this connectivity on the marketplace template, the following additional steps may be required:

1. On a node of the SQL Server cluster, use PowerShell to define a "probe port". The active cluster node will open this port so that the Azure Load Balancer can detect it.  
`Get-ClusterResource "Cluster IP Address" | Set-ClusterParameter -Name "ProbePort" -Value 59998`
2. From the Failover Cluster Manager, ensure that the Core Cluster Resource has a valid IP address for its subnet (this may be configured with an invalid IP address such as 169.254.1.1).
3. On all nodes of the SQL Server cluster, ensure that the Windows Firewall allows inbound TCP traffic on TCP port 59998.
4. Extend the Azure Load Balancer (sqlLoadBalancer) configuration to route connections to the Cluster IP Address.
  - a. Add a Frontend IP Address for the Cluster IP Address, with an IP address matching that configured for the cluster.
  - b. Add a Health Probe for TCP port 59998.
  - c. Add a Load Balancing Rule for Port 445, using the newly created Frontend IP Address and Health Probe. More complicated Azure AlwaysOn deployments, such as those including multiple networks, may require additional steps to allow this connectivity.
5. The default Availability Group Listener is not configured with a TCP Port. Current versions of Delphix require this to be configured with a valid port number, such as the default port 1433. This can be changed via the AlwaysOn object tree in SQL Server Management Studio:

## Requirements for Windows iSCSI configuration

Windows iSCSI configuration requirements are split into two types. These requirements are needed on both staging and target servers.

1. iSCSI configuration required for operational stability.
2. Optional iSCSI parameters for performance improvement.

**[-]** When target environments are discovered, Delphix will configure the Microsoft iSCSI Initiator Service for Automatic startup.

### iSCSI configuration required for operational stability

The following Microsoft iSCSI Initiator configuration parameters are required for the target and staging Hosts. For details about configuring registry settings, see [How to modify the Windows registry](#)

**[-]** You must reboot the Windows server after changing the iSCSI configuration parameters.

Registry key	Registry value	Type	Data
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\iSCSI\Discovery	MaxRequestHold Time	REG_DWORD	0x384 (900)
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Disk	TimeOutValue	REG_DWORD	0x384 (900)
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Class\{4D36E97B-E325-11CE-BFC1-08002BE10318}\<Instance Number>\Parameters	MaxRequestHold Time	REG_DWORD	0x12C (300)

These settings will improve operational stability for VDBs and staging databases. If these settings are not adjusted, SQL Server may raise errors if VDBs are accessed during a temporary infrastructure outage. Affected VDBs may need to be manually restarted using the Continuous Data Engine.

Delphix Knowledge Base article [KB1251](#) includes scripts to validate or set registry parameters so that they meet current Delphix recommendations.

### Optional iSCSI parameters for performance improvement

The following iSCSI Registry setting may improve the performance of SQL Server dSource and VDB on the staging and target hosts.

Registry Key	Registry Value	Type	Data
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces\<Interface GUID>	TcpAckFrequency	REG_DWORD	0x1 (1)

This setting is recommended for storage networks in Microsoft's TechNet article [iSCSI and the Nagle algorithm](#), described in Microsoft's document [TcpAckFrequency to control the TCP ACK behaviour](#)

In some environments, adjusting this setting may not improve performance compared to Windows defaults. Modifications to this registry parameter should be tested in each environment, to confirm that this provides a performance improvement.

#### Delphix engine validation for Windows iSCSI configuration

Delphix Engine validates the Windows iSCSI Configurations that are set on any supported windows staging and target host with the Delphix recommended configurations while performing the following operations:

1. Add environment operation
2. Refresh environment operation
3. Enable environment operation

#### Prerequisites

1. Supported if you are using Powershell 3.0 or above - If you are on Powershell version below 3.0, then the job will be updated with a warning that the Powershell version on your host is not supported for validating iSCSI parameters.
2. The below alerts are applicable only for staging or target Windows hosts.

#### Additional information

1. Delphix Engine will only validate and will not alter any configuration in the user environment.
2. On update of registry values on the target host to match Delphix recommendations, the faults from the Delphix engine will only be resolved if any of the operations (environment add, refresh or enable) is performed. Delphix engine will not monitor the state of the target host in the background and hence any change will not be picked up unless an operation is triggered. So, the user needs to take action for the change to reflect in faults.
3. On a successful Delphix Engine upgrade, the latest default iSCSI recommendations will be used for validations.

#### Troubleshooting

Severity	Type	Description
Warning	iSCSI configuration parameter values on environment <env-name> do not match Delphix Engine required values.	This single fault and/or job warning is thrown for all mismatched parameters.
Warning	Failed to fetch some iSCSI configuration parameters for the environment <env-name>.	This single fault and/or job warning is thrown for all parameters where Delphix Engine fails to fetch the value at the target host.

Severity	Type	Description
Warning	Failed to fetch some iSCSI configuration parameters for host <env-name> due to time out.	This job warning is raised, if Delphix Engine is unable to get the iSCSI parameters on the host within 5 minutes. No fault thrown at this point.
Warning	PowerShell version 3 (or above) is required for fetching iSCSI configuration parameters.	This job warning is raised if the PowerShell version is below 3 on the host during the validation of the iSCSI parameters. No fault thrown at this point. The validation is skipped.

Identifying the instance number for iSCSI control class initiator drivers

1. From the Windows toolbar, click **Start** and select **Run** from the menu.
2. Type `regedit` in the **Open** field and click **OK**.
3. Go to the following registry key:  
 HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Control\Class\{4D36E97B-E325-11CE-BFC1-08002BE10318}\<Instance Number> where the value of <Instance Number> is the one that shows a **DriverDesc** value of **Microsoft iSCSI Initiator**. Under the registry key, locate and expand the plus (+) sign next to the instance number. In the example below, the value of the instance number is 0002.

1 Value of Instance Number

## Windows iSCSI configuration and limits for target and staging hosts

 Windows Limitation

Windows supports up to 255 iSCSI LUNs maximum. This creates a hard limit on the number of VDBs that can be created because each VDB requires one or more iSCSI connections.

## iSCSI connections - staging

1. dSource linked with Logsync disabled = 1 LUN (DATA)
2. dSource linked with Logsync enabled = 2 LUNs (DATA and ARCHIVE)
3. dSource linked with Logsync disabled and SnapShot started (new COPY ONLY FULL BACKUP) = 3 LUNs (DATA and TEMP)
  - a. Once the SnapShot is completed the TEMP LUN will be destroyed and 1 LUN used
4. dSource linked with Logsync enabled and SnapShot started (new COPY ONLY FULL BACKUP) = 3 LUNs (DATA, ARCHIVE and TEMP)
  - a. Once the SnapShot is completed the TEMP LUN will be destroyed and 2 LUNs used
5. A maximum of ~120 dSources per Staging Target is recommended, assuming an average of 2 LUNs per source, which would mean 240 LUNs would be consumed for normal operation.
  - a. The proposed scenario would leave 13 additional iSCSI connections available for COPY ONLY FULL BACKUPS
  - b. For dedicated staging hosts, we do NOT use a Powershell process for monitoring.

## iSCSI connections - targets

1. VDB normal operations = 1 LUN (DATA)
  - a. No extra mounts required for SnapShot restore or refresh from source Snapsync
2. VDB point-in-time log actions (such as restore, refresh or provision from logs) = 2 LUNs (DATA and SOURCE\_ARCHIVE)
  - a. An extra LUN is not required for Snapsync operations, only Logsync
  - b. Most users do not require enablement of the Logsync feature for MSSQL Sources, because sources in FULL RECOVERY mode create a Snapsync for each log file, providing a significant number of restore points even without retaining the logs.
  - c. Once recovery is completed the SOURCE\_ARCHIVE LUN will be destroyed and 1 LUN used
3. A maximum of ~120 VDB's per Target is recommended
  - a. In 4.x, target host iSCSI connections are less likely to be a limitation while processing costs for Powershell threads may become prohibitive because each target VDB requires a Powershell process for monitoring
  - b. In 5.x, this has been alleviated with a hard limit on Powershell processes

## iSCSI connections - V2P

1. V2P normal operation = 1 LUN (DATA)
  - a. Once the V2P operation is completed the DATA LUN will be destroyed leaving no LUNs used
2. V2P point in time log actions (provision from logs) = 2 LUNs (DATA and SOURCE\_ARCHIVE)
  - a. Once the V2P operation is completed both the DATA and SOURCE\_ARCHIVE LUNs will be destroyed leaving no LUNs used

## Network access requirements for SQL Server

### Network architecture

The diagram *Delphix Virtualizing and Masking SQL Server Network Architecture* below depicts the overall network architecture for Delphix virtualizing and masking SQL Server. In the diagram, each of the arrows represents the direction of a network connection between two nodes. Next to each arrow is a label indicating the network protocol (TCP) and the port number indicating the network service. Also, indicated in red are the recommended network latencies between the major components of the architecture.

**i** You can optionally configure a separate Connector Environment, specifically used to discover databases on the source during Environment creation. You can also use your Staging Target Host to be used as the Connector Environment, as seen in the image below.

*Delphix virtualizing and masking SQL Server network architecture*

*Delphix Virtualizing and Masking SQL Server Network Architecture*

### Ports

Based on the table below, the Windows Network Administrator needs to complete a series of tasks. For each port listed, determine whether it must be opened in your firewall between your Delphix Engine and source or target systems. Work with your Delphix Administrator to understand what requirements are there, and ensure that they have been met before proceeding.

Port	Network Service	Required for virtualization?	Required for masking?	Description and usage
22	SSH	Yes	Yes	Used for accessing command-line interface (CLI) and internal Delphix OS accounts
80	HTTP	Yes	No	Used for GUI console access on Delphix Engine by default, disabled when HTTPS in use
443	HTTPS	Yes	No	Used for GUI console access on Delphix Engine, disabled when HTTP in use
445	SMB	Yes	No	Used for attaching shared folders on Windows. To take a copy-only backup or use Delphix Managed backups, this port is required to allow the source environment access to the staging environment.
1433	JDBC	Yes	Yes	Used for accessing SQL Server databases for queries on data-dictionary. This port is the default, but you can use other ports instead. <b>Note:</b> Port 1433 is required between the Delphix Engine and AG (Availability Group) cluster sources.
3260	iSCSI	Yes	No	Used for network-attached storage (NAS) on Windows database servers
8415	DSP	Yes	No	Used for SQL Server hooks, when enabled. This port needs to be open between the Delphix Engine and the VDB target.
(32768-60999)/9100	Delphix Windows Connector	Yes	No	Used for connecting to the Delphix Connector service installed on Windows target database servers.

Port	Network Service	Required for virtualization?	Required for masking?	Description and usage
50001	iPERF	No	No	Used for network throughput testing with the open-source iPerf package through the Delphix CLI, this is purely optional (but useful) functionality

### AppData port requirements

For unstructured files and AppData port requirements, please visit the [Network and Connectivity Requirements for Windows Environment](#) article.

### Applying network access requirements to Windows cluster configurations

Follow the below points to apply Network Access Requirements to Windows Cluster configurations

- For Target Windows Cluster Environments (running Target Failover Cluster Instances), you need to access TCP 445 of the Windows Cluster Virtual IP from the Staging Server.
- For Source Windows Cluster Environments (running Source Always-On Availability Group databases), you need to access the following:
  - From the Staging Server:
    - TCP 445 of the Windows Cluster Virtual IP
    - The SQL Server port (default TCP 1433) of each SQL Server instance running on the cluster
    - The SQL Server port (default TCP 1433) of all Availability Group Listener Virtual IP addresses that contain Source Databases
  - From the Delphix Engine:
    - The SQL Server port (default TCP 1433) of each SQL Server instance running on the cluster
    - The SQL Server port (default TCP 1433) of all Availability Group Listener Virtual IP addresses that contain Source Databases
- For Source Windows Cluster Environments on Azure, some Azure configuration changes may be required, see [Additional requirements for Azure SQL Server Availability Groups](#) for more details.
- For both Source and Target Windows Cluster Environments, the required connectivity for a standalone host should be configured for every node of the cluster. For example, Delphix Engine should be able to connect to the Delphix Connector service installed on each target windows cluster node listening on the Delphix Connector port configured at installation.

## Managing SQL Server environments and hosts

This section describes the attributes of SQL Server environments such as information for the Delphix Connector and covers the following topics:

- [Overview of setting Up SQL server environments](#)
- [Environment attributes for hosts with SQL server](#)
- [Installing the Delphix connector service on the target database servers](#)
- [Upgrading the Delphix connector](#)
- [Manual discovery for SQL server instances](#)
- [Adding a SQL server source environment](#)
- [Adding a SQL server standalone target environment](#)
- [Adding a SQL server failover cluster target environment](#)
- [Additional SQL server environment topics](#)

## Overview of setting up SQL Server environments

This topic describes the high-level process for adding SQL Server environments, linking SQL Server databases to the Delphix Engine, and provisioning virtual databases.

Block diagram of linking architecture between SQL Server environments and the Delphix Engine

Linking Architecture between SQL Server and Delphix Platform

This block diagram shows the host architecture when creating SQL Server Environments in the Delphix Engine. On the left, the Source Host (in this example a Production Database Server) creates backups to a shared backup location. The Delphix Engine (far right), continuously monitors the source database to determine when new backups are available. When a backup is available, the Delphix Engine will contact the Windows Staging host (center) via the Delphix Connector service. The Staging host will read the backups from the shared backup location and recover them through a Staging Database that is automatically set up on Delphix iSCSI storage. Once recovery is complete, the backup data is incorporated into the Delphix dSource as a new snapshot card, and is available for use.

Block diagram of SQL Server provisioning architecture

This block diagram shows how Delphix provisions VDBs to a Target Environment. The Delphix Engine (left) creates a set of virtual files from a snapshot that becomes the VDB container. These files are presented to the Target host (right) via iSCSI. Delphix calls the Delphix Connector on the Target and initiates the creation of a new database using the Virtual files. Once complete, the Virtual Database is brought online and made available for use.

#### The Delphix connector and environment setup

The Delphix Connector is a Windows service that enables the communication between the Delphix Engine and the Windows target environment where it is installed.

- The directory on which you install the Delphix Connector should have at least 1GB of available space.

This target machine can serve three purposes in a Delphix Engine deployment. It can:

1. Serve as a proxy for database discovery on source hosts.
2. Host a staging database for a linked dSource and run the validated sync process.
3. Host a target environment for provisioning virtual databases (VDBs).

Database discovery is initiated during the environment set up process. When you specify a production source environment that contains the databases you want to manage with the Delphix Engine, you must also specify a

target environment where you have installed the Delphix Connector to act as a proxy for communication with the source environment. This is necessary because Delphix does not require that you install the Delphix Connector software on the production source environment. When you register the source environment with the Delphix Engine, the Delphix Engine uses the Delphix Connector on the proxy environment to discover SQL Server instances and databases on the source. You can then create dSources from the discovered databases. If you later refresh the source environment, the Delphix Engine will execute instance and database re-discovery through the proxy host.

SQL Server dSources are backed by a staging database that runs on a target host. There is no requirement for additional local storage on this target host, as the storage is mounted over iSCSI from the Delphix Engine. At Delphix, we refer to the creation and maintenance of this staging database on the staging host as "validated sync," because it prepares the dSource data on the Delphix Engine for provisioning VDBs later on. After the Delphix Engine creates the staging database, it continuously monitors the source database for new transaction log backups. When it detects a new transaction log backup, it restores that backup to the staging database. The result is a TimeFlow with consistent points from which you can provision a VDB, and a faster provisioning process, because there is no need for any database recovery during provisioning.

When you later provision a VDB, you can specify any environment as a target, including the environment that contains the staging database. However, for best performance, we recommend that you choose a different target environment. The only requirements for the target are:

- It must have the Delphix Connector installed.
- It must have an operating system that is compatible with the one running on the validated host, as described in [SQL Server Support and Requirements](#).

#### Toolkit size and predicted growth

Each of the clients that run from the client-side toolkit generates its own logs. Each client generates 4 different log files, one for each level of logging: info, trace, debug, and error. Each level of logging is restricted to a maximum of 10 logfiles, and these logfiles are capped at 10MB each. Therefore, the Delphix Engine will consume a maximum of 400MB per client-side application. On the source server, there are currently two commonly run client-side applications, SnapSyncClient and the Delphix Connector.

 V2P also generates its own logs, so if you intend to V2P to the source, you should account for an additional 400MB in your upper bound.

Thus, the max amount of growth for the toolkit from logging is 800MB without V2P (or 1.2GB with V2P).

Linking additional dSources does not impact the size of the toolkit on production, aside from the log messages generated during linking, which is included in the calculation above.

On the target server, unlike the source server, there would be only one client – the Delphix Connector, which would occupy around 400 MB maximum storage space. In addition, the Delphix Engine pushes new scripts each time you provision a VDB. This requires < 1MB space.

Therefore, the maximum space occupied by the toolkit directory on the source server is its initial size (~ 400MB) + 800MB = 1.2 GB. While on the target server, the maximum toolkit size is initial size (~ 400MB) + 400 MB + Number of VDBs \* 1MB.

## Environment attributes for hosts with SQL Server

This topic describes the attributes of SQL Server environments such as information for the Delphix Connector. Below you will see a section for common environment attributes shared by all types of environments as well as SQL Server-specific ones.

### Procedure

1. Login to the Delphix Management application.
2. Click Manage.
3. Select Environments.
4. In the Environments panel, click the name of an environment to view its attributes.
5. Next to Attributes, click the Pencil icon to edit an attribute.

### Common environment attributes

Attribute	Description
Environment Users	The users for that environment. These are the users who have permission to ssh into an environment or access the environment through the Delphix Connector. For more information on the environment user requirements, see the Requirements topics for specific data platforms.
Host Address	The IP address of the environment host.
DSP KeyStore Path	The path to the user-managed DSP Keystore.
DSP KeyStore Alias	The lowercase alias to use inside the user-managed DSP Keystore.
DSP KeyStore Password	The password for the user-managed DSP Keystore.
DSP TrustStore Path	The path to the user managed DSP truststore.
DSP TrustStore Password	The password for the user managed DSP truststore.
OS	The name of the host operating system.
Version	The version of the host operating system.
Release	The release of the host operating system.
Time Zone	The timezone of the host operating system.
Total RAM	The amount of RAM on the host machine.

Attribute	Description
Processor Type	The processor type of the host machine.
Traceroute	Traceroute info from target host to Delphix Engine.
Notes	Any other information you want to add about the environment.
Java Development Kit	The currently selected JDK kit will be shown.
Java Development Kit (JDK) Path	Location of the Java Development Kit (JDK) used for the host. Only specified if the feature to provide your own JDK is enabled, otherwise, the defaults are used per our <a href="#">Java Support Matrix</a> .

## SQL server environment attributes

Attribute	Description
Installed Powershell Version	The PowerShell version installed on the windows target host. This is not applicable for Windows source environments.
Delphix Connector Path	The path for the toolkit that resides on the host.
Delphix Connector Port	The port that the connector connects on.
Delphix Connector Version	The Windows Connector version that is installed on the provided host.
.NET Framework Version	The .NET Framework version used for Windows Connector Service.
Delphix Connector Host	The connector host for a windows environment. This is not applicable for Windows target environments.

## Installing the Delphix connector service on the target database servers

This section lists the steps involved in installing a Delphix Connector on your target database server. Installing the Delphix Connector is vital for communication between the Delphix Engine and the targets. A minimum available space of 1GB is a prerequisite to installing the Delphix Connector.

1. From the machine that you want to use as a target, start a browser session and connect to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next to **Environments**, click the **Plus** icon.
5. In the **Add Environment** dialog, select **Windows** from the **operating system** menu.
6. Select **Target**.
7. Select **Standalone**.
8. Click **Next**.
9. Click the download link for the **Delphix Connector Installer**.

The Delphix Connector will download to your local machine.

**Note:** You can also download the Delphix Connector directly by navigating to this URL: `http://<name of your Delphix Engine>/connector/DelphixConnectorInstaller.exe`

10. On the Windows machine that you want to use as a target, run the Delphix Connector installer. Click **Next** to advance through each of the installation wizard screens.

**Note:**

The installer will only run on 64-bit Windows systems. 32-bit systems are not supported.

- a. For **Connector Configuration**, make sure there is no firewall in your environment blocking traffic to the port on the target environment that the Delphix Connector service will listen to.
- b. For **Java Configuration**, to provide your own Oracle Java enter the absolute path to your Oracle JDK and click **Next**. Otherwise, leave the field blank.

**Note:**

The NETWORK SERVICE user requires read and execute permissions on the Oracle JDK, its subfolders, and files.

- c. For **Select Installation Folder**, either accept the default folder or click **Browse** to select another.
- d. For **Choose .NET Framework (Delphix Engine 6.0.5.0 onwards)**, select which version of .NET should be used by the Delphix Connector Windows service. The installer will default to the latest version detected on the system. This selection can be changed afterwards but make sure that chosen .NET framework version should exist in the system.
- e. Click **Next** on the installer final **Confirm Installation** dialog to complete the installation process.
- f. For successful installation a popup will come up stating "**DelphixConnector Installed Successfully**".
- g. Click **Close** to exit the Delphix Connector Install Program.

## Relocating the Delphix connector

There are times when the Delphix Connector installation requires a move to a different directory or drive. It's not a trivial relocation. This requires disabling dSources and/or VDBs, uninstalling the current install and reinstalling to the new location. In addition to this, an upgrade to the Delphix Connector can also be achieved via the uninstall/reinstall methodology, including a change in location. These instructions cover 4.0 through 5.1. The steps are the same up to 5.1.2.0. At that version and forward it is no longer required to use the CLI to change the Delphix Connector location. All one needs to do is refresh the Delphix Connector environment and the new directory location is discovered and updated on the Delphix Engine. In the steps listed below, the example is moving the connector from "C:\Program Files" to "C:\", so the full connector path is "C:\Delphix\DelphixConnector".

1. **Disable** the **dSources** and/or **VDBs** associated to the **DelphixConnector** host. This will unmount the storage from the Windows host, removing the directories, the **dSources** represented by the staging databases, and the **VDBs**.
  - a. **dSource** staging directories are in the form of "guid-staging-xx", where xx is the staging database number
  - b. **VDB** directories are appended with "guid-vdb-xx".
2. When all **VDBs** and **dSources** are disabled and you are ready to move the **DelphixConnector** location, stop the **DelphixConnector** service.
3. Backup the remaining directories as a precaution, in particular, the **logs** directory.
4. Uninstall the **DelphixConnector**, using the instructions from [Uninstall the Delphix Connector](#).
5. Reinstall the **DelphixConnector** to the new location, such as "C:\Delphix\DelphixConnector". Check that the **DelphixConnector** service has started.
6. Modify the new **DelphixConnector** location.
  - a. On Delphix engine versions **prior to 5.1.2.0**, use the CLI to modify the directory

```
i. de4350.dcenter host> select winhost.delphix.com
de4350.dcenter host 'winhost.delphix.com'> update
de4350.dcenter host 'winhost.delphix.com' update *> set toolkitPath="
C:\Delphix\DelphixConnector"

de4350.dcenter host 'winhost.delphix.com' update *> commit
Dispatched job JOB-3203
HOST_UPDATE job started for "winhost.delphix.com".
HOST_UPDATE job for "winhost.delphix.com" completed
successfully.
```

- ii. Refresh the windows environment for the change to take effect.
  - b. On engine versions **5.1.2.0 and higher**, you only need to refresh the windows environment.
7. Enable the **dSources** and/or **VDBs**.

## Replacing self-signed certificates on the Delphix connector

The Delphix Connector relies on a Java Keystore with a self-signed X.509 certificate in order to instantiate SSL. If this certificate does not conform to the customer's business standards, it is possible to run a PowerShell script (ReplaceConnectorKeystore.ps1) to replace the self-signed certificate with a certificate that is signed by a Certificate Authority of their choice (i.e. Verisign).

This script should only be used to replace the self-signed certificate in the Delphix Connector's Java Keystore with a signed certificate. Upon execution, the script will do the following:

1. Validate that a PrivateKeyEntry exists within the input keystore
2. Stop the DelphixConnector service
3. Rename the existing DelphixConnector keystore
4. Import the new keystore
5. Start the DelphixConnector service

### Prerequisites:

1. The Delphix Connector is installed
2. The DelphixConnector.jks file exists at <Drive>:\<path to DelphixConnector>\connector\DelphixConnector.jks
3. The DelphixConnector.properties file exists at <Drive>:\<path to DelphixConnector>\connector\DelphixConnector.properties and has not been tampered with (STOREPASS, KEYPASS, UUID are present)
4. The Java Keytool utility exists at <Drive>:\<path to DelphixConnector>\jre\bin\keytool.exe
5. The script, ReplaceConnectorKeystore.ps1 exists at <Drive>:\<path to DelphixConnector>\connector\ReplaceConnectorKeystore.ps1

### User inputs:

1. A JKS/PKCS#12 formatted keystore containing a PrivateKeyEntry with a signed certificate
2. The alias of the PrivateKeyEntry in the new keystore
3. The password for the new JKS/PKCS#12 keystore
4. The password for the private key in the new JKS/PKCS#12 keystore

### Running the script:

Open up a PowerShell console, and do the following:

1. Navigate to where ReplaceConnectorKeystore.ps1 lives
2. Run .\ReplaceConnectorKeystore.ps1
3. Enter the full path to the new JKS/PKCS#12 keystore
4. Enter the alias of the PrivateKeyEntry in the input keystore
5. Enter the password for the input keystore
6. Enter the password for the private key in the input keystore

### How to check if your Java keystore contains a privateKeyEntry:

```
PS C:\Program Files\Delphix\DelphixConnector\jre\bin> .\keytool.exe -list
-keystore ..\..\connector\DelphixConnector.jks
-storepass <STOREPASS from DelphixConnector.properties file>
Keystore type: JKS
Keystore provider: SUN
Your keystore contains 1 entry
delphixconnector-4ef488a8-85df-4418-b56d-1e61b25c0aa2, Jul 28, 2017, PrivateKeyEntry,
```

```
Certificate fingerprint (SHA1): 67:79:DA:E2:64:7A:74:42:62:CA:13:66:29:16:81:0A:B9:7E:4A:60
```

**Example of a successful keystore replacement:**

```
PS C:\Users\dtully\Documents> .\ReplaceConnectorKeyStore.ps1
Enter the full path to a JKS/PKCS#12 keystore: C:\Program
Files\Delphix\DelphixConnector\jre\bin\test.jks
Enter alias: leaf
Enter keystore password: *****
Enter private key password: *****
Verifying that a PrivateKeyEntry exists in C:\Program
Files\Delphix\DelphixConnector\jre\bin\test.jks
Stopping the Delphix Connector service
Renaming C:\Program Files\Delphix\DelphixConnector\connector\DelphixConnector.jks to
C:\Program Files\Delphix\DelphixConnector\connector\DelphixConnector.jks.old
Importing the keystore into DelphixConnector.jks
[Storing C:\Program Files\Delphix\DelphixConnector\connector\DelphixConnector.jks]
Starting the Delphix Connector service
```

## Uninstalling the Delphix connector service from the target database servers

On occasion, the installed Delphix Connector may become out of date as newer versions of Delphix are released to improve stability or performance.

The following steps can be used to uninstall and reinstall the Delphix Connector as required:

- Uninstall the Delphix Connector
- Download the latest installer from your Delphix Engine
- Reinstall the Delphix Connector

While the Delphix Connector is uninstalled on target/staging environments, dSource and virtual database (VDB) operations (such as validated sync, manual snapshots, and provisioning operations) initiated by the Delphix Engine against those environments will fail.

When working with target/staging environments, or Delphix Engines with a large number of users, to reduce the risk of confusion or failure for other users consider disabling each dSource in the environment. In the case of VDBs, there is no need to disable or shutdown. If SnapSync, refresh or other VDB operations occur during the uninstall/install they can be restarted once the procedure is complete. This prevents the need to incur more downtime.

## Uninstalling the Delphix connector

Before uninstalling the Delphix Connector, the following steps should be performed using the Delphix Management application:

1. Login to the Delphix Management application as an admin. **Note:**  
As a precaution, you can backup the binary directories, such as bin, connector, service, scripts, etc, to a temporary location.
2. Copy the logs directory, since uninstall will remove this directory. VDB or Staging folders can not be moved since the data is an iSCSI data mount. These will not be removed or manipulated during uninstall/reinstall.
3. Verify that no VDB provisioning or refresh operations are currently being performed on the target/staging environments.
4. If the environment being upgraded is a staging environment for any dSources, disable all dSources using this environment.
5. Just prior to disabling dSources, use the following query on each SQL Server instance to verify that no operations are currently running.  
Show Restore Operations

```
SELECT r.session_id, r.command, CONVERT(NUMERIC(6,2), r.percent_complete) AS
[PercentComplete], CONVERT(VARCHAR(20), DATEADD(ms,r.estimated_completion_time,
GetDate()),20) AS [ETACompletionTime], CONVERT(NUMERIC(10,2),
r.total_elapsed_time/1000.0/60.0) AS [ElapsedMin], CONVERT(NUMERIC(10,2),
r.estimated_completion_time/1000.0/60.0) AS [ETAMin], CONVERT(NUMERIC(10,2),
r.estimated_completion_time/1000.0/60.0/60.0) AS [ETAHours], CONVERT(VARCHAR(10
00), (SELECT SUBSTRING(text, r.statement_start_offset/2, CASE WHEN
r.statement_end_offset = -1 THEN 1000 ELSE (r.statement_end_offset-
r.statement_start_offset)/2 END) FROM sys.dm_exec_sql_text(sql_handle)))
FROM sys.dm_exec_requests r
WHERE command IN ('RESTOREDATABASE', 'BACKUPDATABASE', 'RESTORELOG', 'BACKUPLOG')
```

**Note :** If your Windows Server is used as a Staging / Validated Sync Target for one or more linked dSources, uninstalling the connector while a Validated Sync operation (i.e. database restore) is in progress may leave the database in an inconsistent state. Validated Sync operations are not visible in the Delphix GUI, so it is necessary to query the SQL Server instance(s) on this server directly to check whether a restore is in progress.

6. If any operations are in progress, wait for them to complete before disabling dSources. Once complete, disable dSources and proceed with the uninstall.

On the Target/Staging Environment (where the Delphix Connector is being upgraded):

1. From the Windows Services manager, Stop the **Delphix Connector Service**.
2. Via the **Task Manager** verify that the java process associated with the **Delphix Connector** has terminated.
3. From **Control Panel** select **Programs and Features**, then navigate to **Delphix Connector**, right-click it and select **uninstall**.
4. Install the new connector from the downloaded **DelphixConnectorInstaller.msi** or **DelphixConnectorInstaller.exe** file. For more information refer to [Installing the Delphix Connector Service on the Target Database Servers](#).
5. Check the **Delphix Connector** version from the **Programs and Features** list. For more information on Connector versions please refer to [How To Determine Connector Version](#).
6. Check the **Delphix Connector** service is running and set to automatic.
7. Verify your system is now working properly. You may need to manually start any disabled dSources or VDBs from the Delphix UI. For more information refer to [Managing Data Sources and Syncing Data](#).

## Troubleshooting Delphix connector

### Troubleshooting removing the Delphix connector

If there are issues removing the original Delphix Connector please refer to these steps:

- You can remove the DelphixConnector from Control Panel > Program and Features.

### Troubleshooting Delphix connector install

If you experience the following issues when re-installing the Delphix Connector refer to, [Reinstall/Upgrade the Delphix Connector](#).

- Delphix Connector service might disappear from the service console.
- Installation failing with unidentified service error.
- The Delphix connector upgrade failed.
- Manually deleted the Delphix Connector folder to try reinstalling.

### Troubleshooting if the Delphix connector service fails to start

- Check if the Delphix Connector service is available and running on the Staging Host. If it is not running, then start the service.
- If the Delphix Connector service automatically shuts down or has restarting problems, kill the running java process started by Delphix connector and then retry starting the Delphix Connector Service.
- Open a command prompt (cmd) as administrator.
- From the prompt run: `netstat -noba | findstr "9100 java"`. If the connector is still running, the output should be similar to this:

```
C:\Users\username>netstat -noba | findstr "9100 java"
[java.exe]
TCP    0.0.0.0:9100          0.0.0.0:0          LISTENING        1928
[java.exe]
TCP    [::]:9100         [::]:0             LISTENING        1928
[java.exe]
```

The final number on each line is the Process ID (PID) of the Delphix Connector process.

- If there is a java process bound to port 9100 as shown above, but the Delphix Connector still fails to start, you can kill the Java process using the taskkill command:

```
C:\Users\username>taskkill /PID 1928 /F
SUCCESS: The process with PID 1928 has been terminated.
```

Alternatively, you can use Task Manager or Process Explorer to identify and end the correct process/PID and end it from there.

- Start the Delphix Connector service.

If the service still fails to start after performing the above steps, please attempt to reinstall the Delphix Connector. If issues persist, contact Delphix Support for assistance.

### Troubleshooting if installation of third party software results in Delphix connect service to fail to start

- If third party software is installed on the Windows host running Delphix Connector and upon the reboot, Delphix Connector doesn't startup, please uninstall the Software and revert the host back to the state it was in before the software deployment and then check if the Delphix Connector service starts

- If it doesn't start check the steps in the section "The Delphix Connector service fails to start".
- If the service still doesn't start please open a Support case with Delphix for further investigation.

## Upgrading the Delphix connector

The installed Delphix Connector may become outdated as newer versions of Delphix are released to improve stability or performance.

Upgrading the Delphix connector is a two-step process, which includes

- [Uninstalling the Delphix connector](#)
- [Installing the Delphix connector](#)

While the Delphix Connector is uninstalled on target/staging environments, dSource and virtual database (VDB) operations (such as validated sync, manual snapshots, and provisioning operations) initiated by the Delphix Engine against those environments will fail.

When working with target or staging environments or Delphix Engine with a large number of users to reduce the risk of confusion or failure for other users consider disabling each dSource in the environment. In the case of VDBs, there is no need to disable or shut down. If SnapSync, refresh or other VDB operations occur during the uninstall/install they can be restarted once the procedure is complete. This prevents the need to incur more downtime.

**If you are using the certificate that is signed by a certificate authority on the Delphix connector**, you can use either of the following ways:

1. After upgrading the Delphix connector, re-execute the steps of [Replacing Self-signed Certificates on the Delphix Connector](#).
2. If you want to use the existing certificates, make sure to follow the below steps:
  - Before uninstalling, you must back up `DelphixConnector.jks` file and properties such as `Keystore`, `Keypass`, `Storepass` and `UUID` from `DelphixConnector.properties` file to a temporary location.
  - Uninstall the Delphix connector.
  - Install the Delphix connector.
  - Stop the Delphix connector service.
  - You can now copy the backed-up .jks file and properties.
  - Paste the backed-up .jks file inside the installation directory and the properties to the `DelphixConnector.properties` file.
  - Ensure that the `Keystore`, `Keypass`, `Storepass` and `UUID` properties are kept unchanged, and `Keystore` property must point to the correct installation directory.

**Note** : For example, if the Keystore is `C:\Program Files\Delphix\Delphix Connector\connector\DelphixConnector.jks`, make sure to place this .jks file in the same path as mentioned in Keystore.

**If you are using windows connector host authentication**, you can use either of the following ways:

1. After upgrading the Delphix connector, re-execute the steps for [windows connector host authentication](#).
2. If you want to use the existing configuration of windows connector host authentication, make sure to follow the below steps:
  - Before uninstalling, you must back up `DelphixConnector.jks` file and properties such as `Keystore`, `Keypass`, `Storepass` and `UUID` from `DelphixConnector.properties` file to a temporary location.
  - [Uninstall the Delphix connector](#) and then
  - [Install the Delphix connector](#).
  - Stop the Delphix connector service.

- You can now copy the backed-up .jks file and properties.
- Paste the backed-up .jks file inside the installation directory and the properties to the `DelphixConnector.properties` file.
- Ensure that the `Keystore`, `Keypass`, `Storepass` and `UUID` properties are kept unchanged, and `Keystore` property must point to the correct installation directory.

 For example, if the Keystore is `C:\\Program Files\\Delphix\\Delphix Connector\\connector\\DelphixConnector.jks`, make sure to place this .jks file in the same path as mentioned in Keystore.

## Manual discovery for SQL Server instances

Occasionally, SQL Server instances cannot be automatically discovered due to a problem in the Windows registry or if the instance is not running at that time. These SQL Server instances can be discovered using manual discovery.

### Manually adding a SQL Server instance

To manually add a SQL Server instance

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments** and select the **Databases** tab.
4. Click the **Add Instance** button and enter the following details:
  - a. To allow linking and/or provisioning, select **Enabled**.
  - b. If this environment will be used as a staging environment, select **Enabled**.
  - c. Selecting **Enabled** for Fulltext Installed allows users to do full-text searches.
  - d. Add as a **Failover Cluster Source**: When this is Enabled users are asked to enter the Server name.  
**Note:** This option is only applicable when adding a SQL Server failover cluster instance as a source, it is not available for clusters as a target.
  - e. **Name**: Not currently used.
  - f. **Port**: Used for IPC connection to the instance.
  - g. **Installation path and instance owner**: Installation path of SQL Server. Not currently used.
  - h. **Internal version**: The internal version of the SQL Server. This is important during linking and provisioning as the compatible instance is identified based on the internal version.
  - i. **Version**: the SQL Server Version required for adding a source instance. **Note:** If the wrong version is entered, Delphix may fail to discover the databases and hence manual discovery may fail.
5. Click **Add**. At this time, if all values are correct, an instance will be created and all its databases will be auto-discovered internally.

 If Delphix Engine is not able to establish a connection using given details, appropriate errors will be displayed and the user will be asked to make the required changes.

### Editing a SQL Server instance

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. In the **Environments** panel, select the **Databases** tab.
5. Click the **Pencil** icon to edit an instance.  
If you are editing an instance which you added, you will be able to edit: - You will be able to edit all fields except the name.
6. Click **Save**.

### Refresh a manually added SQL Server instance

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. In the **Environments** panel, click the **refresh** icon on top.
5. Along with auto-discovered instances, it will now also refresh manually added instances and add/remove its databases, based on the current state of the instance.

- ☐ If Delphix Engine is not able to establish a connection to the instance, then the appropriate warning will be displayed to the user during database discovery.

#### Deleting a manually added SQL Server instance

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. In the **Environments** panel, select the **Databases** tab.
5. You will see a delete icon at the far right of all manually added instances.
6. Click **Delete**. This will delete the instance and all its databases.

- ☐ This operation will fail if the chosen instance has databases that have dependencies such as database being used to provision VDBs etc.

## Adding a SQL Server source environment

This topic describes how to add a SQL Server source environment.

### Prerequisites

- You must have already set up SQL Server target environments, as described in [Adding a SQL Server Standalone Target Environment](#).
  - You will need to specify a target environment that will act as a proxy for running SQL Server instance and database discovery on the source, as explained in [Overview of Setting Up SQL Server Environments](#)
- Make sure your source environment meets the requirements

### Procedure

- Login to the **Delphix Management** application.
- Click **Manage**.
- Select **Environments**.
- Next to **Environments**, click the **Actions** menu and select **Add Environment**.
- In the **Add Environment** wizard, Host and Server tab select:
  - Host OS: **Windows**
  - Host Type: **Source**
  - Server Type:
    - If you are adding a Windows Server Failover Cluster (WSFC), add the environment based on which WSFC feature the source databases use:
      - Failover Cluster Instances Add the environment as a **standalone** source using the **cluster name** or **address**.
      - AlwaysOn Availability Groups Add the environment as a **cluster** source using the **cluster name** or **address**.
    - Otherwise, add the environment as a **standalone** source.
- Click **Next**.
- In the Environment Settings tab select a **Connector Environment**.  
Connector environments are used as proxy for running discovery on the source. If no connector environments are available for selection, you will need to set them up as described in [Adding a SQL Server Standalone Target Environment](#). Connector environments must:
  - have the Delphix Connector installed
  - be registered with the Delphix Engine from the host machine where they are located.
- Enter the **Environment Name**, **Node Address**, **OS Username**, and **OS Password** for the source environment.
- Click **Submit**.

As the new environment is added, you will see multiple jobs running in the Delphix Admin Job History to Create and Discover an environment. In addition, if you are adding a cluster environment, you will see jobs to Create and Discover each node in the cluster and their corresponding hosts. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel. If you don't see it, click the **Actions** menu and select **Refresh All**.

## Adding a SQL Server standalone target environment

This topic describes how to add a SQL Server standalone target environment to the Delphix Engine.

You can use SQL Server targets for three purposes in a Delphix Engine deployment. They can:

- Host a target environment for the provisioning of Virtual Databases (VDBs).
- Host a staging database for a linked dSource and run the validated sync process.
- Serve as a proxy host for database discovery on source hosts.

Regardless of the specific purpose, all Windows targets must have the Delphix Connector installed to enable communication between the host and the Delphix Engine. The instructions in this topic cover initiating the Add Target process in the Delphix Engine interface, running the Delphix Connector installer on the target machine, and then verifying that the target has been added in the Delphix Engine interface.

 When target environments are discovered, Delphix will configure the Microsoft iSCSI Initiator Service for Automatic startup.

### Prerequisites

- Make sure that your target environment meets the requirements described in the following sections:
  - [SQL Server Support and Requirements](#)
  - [Requirements for Windows iSCSI Configuration](#)
  - [Receive Side Scaling \(RSS\) for Windows Staging Target and Targets](#)
- The Directory on which you install the Delphix Connector should have at least 1GB of available space.

If you have taken a snapshot on Windows 2012 or an earlier version, the provisioning, linking, or exporting to Windows 2022 will result in disk errors. Windows event logs list these errors. You can ignore these errors or run the `CHKDSK \F` command.

### Procedure

1. From the machine that you want to use as a target, start a browser session and connect to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next to **Environments**, click the **Actions** menu and select **Add Environment**.
5. In the **Add Environment** wizard Host and Server tab, select:
  - a. Host OS: **Windows**
  - b. Host Type: **Target**.
  - c. Server Type: **Standalone**.
6. Click **Next**.
7. In the Environment Settings tab click the download link for the **Delphix Connector Installer**. The Delphix Connector will download it to your local machine.
8. On the Windows machine that you want to use as a target, run the Delphix Connector installer. Click **Next** to advance through each of the installation wizard screens.
 

The installer will only run on 64-bit Windows systems. 32-bit systems are not supported.

  - a. For **Connector Configuration**, make sure there is no firewall in your environment blocking traffic to the port on the target environment that the Delphix Connector service will listen to.
  - b. For **Select Installation Folder**, either accept the default folder or click **Browse** to select another.
  - c. Click **Next** on the installer final 'Confirm Installation' dialog to complete the installation process and then **Close** to exit the Delphix Connector Install Program.

9. Return to the Delphix Management application.
10. Enter the **Environment Name, Host Address, Delphix Connector Port, OS Username, and OS Password** for the target environment.
11. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
12. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
13. Click **Submit**.  
As the new environment is added, you will see two jobs running in the **Delphix Admin Job History**, one to **Create and Discover** an environment, and another to **Create** an environment. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel.

#### Post-requisites

1. On the target machine, in the **Windows Start Menu**, click **Services**.
2. Select **Extended Services**.
3. Ensure that the **Delphix Connector** service has a **Status** of **Started**.
4. Ensure that the **Startup Type** is **Automatic**.

## Adding a SQL Server failover cluster target environment

This topic describes how to add a SQL Server failover cluster target environment to the Delphix Engine.

Adding a failover cluster target environment will discover SQL Server failover cluster instances that are running. You can then provision virtual databases (VDBs) to these failover cluster instances.

### Prerequisites

- You must add each node in the Windows Failover Cluster individually as a standalone target environment using a non-cluster address. See [Adding a SQL Server Standalone Target Environment](#).
  - For a cluster node added as a standalone environment, the Delphix Engine will only discover **non-clustered** SQL Server instances.
  - For a cluster target environment, the Delphix Engine will only discover SQL Server **failover cluster** instances.
- Each clustered SQL Server instance must have at least one clustered disk added to the clustered instance resource group, which can be used for creating mount points to Delphix storage.**
  - The clustered drive must have a drive letter assigned to it.
  - The clustered drive must be formatted using the "GUID Partition Table (GPT)" partition style in order for the Delphix Engine to automatically discover the drive letter as a valid option for the cluster instance. An MBR-formatted disk requires manual verification outside of Delphix that the disk has been correctly added to the MSSQL clustered resource group prior to creating the VDB. When provisioning the VDB, you must manually specify the desired MBR disk, because it will not appear in the Delphix GUI.
  - The clustered drive must be added to the clustered instance resource group as a dependency in the Failover Cluster Manager.
- Each node in the cluster must have the **Failover Cluster Module for Windows Powershell** feature installed.
  - While running Windows PowerShell as an administrator, enter this command to load the module:
 

```
import-module failoverclusters
```
- An additional target environment that can be used as a **Connector Environment** must exist. This environment must NOT be a node in the cluster. See [Adding a SQL Server Standalone Target Environment](#).

Hotfix required for Windows 2008 R2 hosts

The following hotfix is required for Windows 2008 R2 Cluster nodes:

**"0x80070490 Element Not found" error when you enumerate a cluster disk resource by using the WMI MSCluster\_Disk class query in a Windows Server 2008 R2-based failover cluster**

<http://support.microsoft.com/kb/2720218>

Windows Cluster Volume Management Software Requirements Only cluster volumes managed by the native Windows Volume Manager are supported. For example, cluster volumes managed by Veritas VxVM are not supported.

If you use third-party volume management software, create a new LU (recommended to be 10GB in size) and add this LU as a clustered resource to the SQL Server instance using native Windows volume management tools. Assign a drive letter for this LU. You can then use this LU as the volume mount point location for Delphix VDB provisioning.

### Best Practices

SQL Server failover cluster instances that the Delphix Engine will use should not be used to host databases other than Delphix VDBs.

**Cluster environment restrictions**

You cannot use failover cluster target environments as staging environments.

However, for VDB **target hosts**, it is important to use the **same edition** of SQL Server software as the **source database**, so that all features available in the source are also available in the VDB.

Supported roles for each instance type

Failover Cluster Instances, and instances supporting Always On Availability Groups, support a subset of the operations available to Standalone SQL Server instances.

Color		Supported?		
Y		Yes		
N		No		
		Environment Role		
Instance Type	Added As	Source Environment	Staging Environment	Target Environment
Standalone Instance	Standalone	Y	Y	Y
Failover Cluster Instance (FCI)	Standalone	Y	N	N
Failover Cluster Instance (FCI)	Cluster	N	N	Y
Always On Availability Group (AG)	Cluster	Y	N	N

\* Databases that are participating in Availability Groups will not be discovered during the discovery of a Standalone environment.

VDBs cannot be provisioned into availability groups. However, SQL Server instances that participate in an Availability Group can also be added as Standalone Instances.

**Warning:** Using a Failover Cluster Instance as both Source and Target  
 A Failover Cluster Instance added as an environment once (as either a Source or Target environment) cannot be used as both a Source and Target.  
 If this is required, the environment can be added twice:
 

- Once as a Standalone Source environment

- Once as a Cluster Target environment

The Standalone Source environment can be used for linking dSources, and the Cluster Target environment is used for provisioning VDBs.

As suggested by the Best Practice note earlier in this article, this is not a recommended configuration. Where possible, SQL Server failover cluster instances that the Delphix Engine will use as a target should not be used to host databases other than Delphix VDBs.

 If you have taken a snapshot on Windows 2012 or an earlier version, the provisioning, linking, or exporting to Windows 2022 Failover Cluster Target might result in disk errors. In such a case, contact Delphix Customer Support

 **Error**  
The following error may be encountered during the Windows 2022 AG and FCI clusters creation process on VMware ESXi.

```
An error occurred while executing the test.Unable to connect to
<hostname.domainname.com> via WMI. This may be due to networking issues
or firewall configuration href="http://
hostname.domainname.com">hostname.domainname.com>.Invalid namespace
```

This failure is due to `Validate switch enabled Teaming configuration validation`. The workaround is to skip this validation.

## Procedure

1. Click **Manage**.
2. Select **Environments**.
3. Next to **Environments**, click the **Plus** icon and select **Add Environment**.
4. In the **Add Environment** wizard, Host and Server tab select:
  - a. Host OS: **Windows**
  - b. Host Type: **Target**.
  - c. Server Type: **Cluster**.
5. Click **Next**.
6. In the Environment Settings tab specify the environment Name and cluster address of the Windows Failover Cluster.
7. Select a host that is NOT a node in the cluster as the **Connector Environment**.
8. Enter the **OS Username** and **OS Password** for the target environment.
9. Click **Validate Credentials**.
10. Click **Submit** to confirm the target environment addition request.

In the Delphix Engine interface, you will see a new icon for the target environment, and two jobs running in the **Delphix Admin Job History**: one to **Create and Discover** an environment, and another to **Create** an environment. When the jobs are complete, click the icon for the new environment, and you will see the details for the environment.

Example environment

In this example environment, the Delphix Connector was installed on **Connector Environment**, **Cluster Node 1**, and **Cluster Node 2**. Each host was added to Delphix as standalone target environments.

Next, the **Windows Failover Cluster** was added as a Windows Target Cluster environment using the cluster address. **Cluster Node 1** is currently the active node for the SQL Server Failover Cluster resource group. Delphix has exported iSCSI LUs and has created the corresponding Cluster Disk resources for each VDB.

## Additional SQL Server environment topics

This section covers the following topics:

- [Microsoft SQL Server bypass powerShell execution policy](#)
- [Delphix as a backup solution to SQL Server](#)
- [Delphix managed backups on secondary nodes of SQL Server alwaysOn availability group cluster](#)
- [Receive side scaling for Windows staging target and targets](#)
- [Validated sync environment](#)
- [Changing the hostname \(IP address\) or IQN of a SQL Server target or staging host](#)

### Microsoft SQL Server bypass PowerShell execution policy

Hooks are executed with “PowerShell -ExecutionPolicy RemoteSigned” whereas user-configured pre/post sync and pre/post provision PowerShell scripts are executed with “PowerShell -ExecutionPolicy Bypass”. If this PowerShell configuration exceeds the security privileges of business standards, a Group Policy Object can be configured in Windows to manage PowerShell execution policy. If configured, we require that the script execution policy is set to “RemoteSigned”. The primary benefit is that the Group Policy configuration takes precedence and overrides the execution policy set in PowerShell, even if you run PowerShell as an Administrator. Alternatively, using MSSQL hooks instead of pre/post scripts will naturally execute with a “RemoteSigned” execution policy.

Refer to the Microsoft Documentation on Execution Policies for more information: [https://docs.microsoft.com/en-us/powershell/module/microsoft.powershell.core/about/about\\_execution\\_policies?view=powershell-6](https://docs.microsoft.com/en-us/powershell/module/microsoft.powershell.core/about/about_execution_policies?view=powershell-6)

The Group Policy is per machine and will apply to PowerShell 2.0 and later.

## Delphix as a backup solution to SQL Server

### Using Delphix as a backup solution to SQL Server

Delphix provides you the option to automatically manage backups from SQL Server source databases into the Delphix Engine. Prior to Delphix 4.2, users could not link source databases that were backed up by unsupported backup software. In Delphix 4.2, a feature known as Delphix Managed Backups was introduced that allows you to have Delphix take and manage backups from your source database directly into Delphix storage. This is the first step in Delphix becoming a full-featured backup solution for SQL Server databases. When the Delphix Engine manages the backups for a dSource, it takes regular, copy-only full backups of the source database, so activating the feature will not interfere with existing backup management solutions. You can configure the schedule of when the Delphix Engine takes these copy-only full backups by specifying a SnapSync policy for the dSource. You can change the SnapSync policy for a dSource at any time by visiting the policy screen; there, you can either select a new SnapSync policy or modify the current one.

If you use a backup solution that is not supported by Delphix, you cannot use your existing backups to keep your dSources in sync. However, enabling Delphix Managed Backups will overcome this issue by using automatic copy-only full backups to keep dSources in sync. Currently, dSources linked when this feature is enabled will not support LogSync functionality, which means that you can only provision VDBs from snapshots and not from any time between snapshots. Additionally, in the current release, the Delphix Engine cannot take differential or transaction log backups of the source database.

### Linking SQL Server dSources with Delphix managed backups

The **Data Management** page of the link wizard for SQL Server dSources provides the option to enable Delphix Managed Backups.

It possible to enable this feature here at link time or toggle it on after the link for future syncs. If you enable this feature, the dSource can only use copy-only full backups taken by the Delphix Engine to stay in sync with its source; the Delphix Engine will prohibit syncing using existing backups. Checking the **Enabled** box results in the following changes to the **Data Management** page:

- The initial load option is set to a copy-only full backup taken by the Delphix Engine
- The ability to provide a backup path disappears
- A SnapSync policy selection screen appears in the **Policies** page

You can select from the list of existing SnapSync policies if the one you want doesn't exist you will need to create a new one on the **Policies** page under the **Manage** dropdown. Proceeding through the remainder of the link wizard will create a dSource with Delphix-managed backups enabled. You can confirm that a dSource has the feature by selecting the dSource and going to the **Configuration > Data Management** tab after creation and checking the **Delphix Managed Backups** section, as displayed below:

 Delphix\_Admin 

Timeflow	Status	Configuration		
Source	Policies	Data Management	Masking	Hooks
VALIDATED SYNC CONFIGURATION 				
	<b>Delphix Managed Backups</b> Yes			
	<b>Force Compression</b> No			
	<b>Encryption Key</b> Yes			
	<b>Netbackup Ingestion</b> Disabled			
	<b>Commvault Ingestion</b> Disabled			

**To disable/enable this feature after linking:**

Toggling Delphix Managed backups is supported for SQL Server dSources. This means a dSource that was previously created with Delphix Managed Enabled can have regular validated sync and similarly a dSource that had external backups can use Delphix Managed Backups.

To disable Delphix Managed Backups for a specific dSource, select that specific dataset and go to **Data Management** tab under the **Configuration** tab.

Click the edit button and uncheck this feature. Then update all new inputs.

To enable this feature just go to the same edit menu.

Backup compression feature overview

Since Delphix Engine 5.2, the Delphix Engine has allowed compression to be enabled ("forced") for SQL Server backups which use Delphix Managed Backups. Delphix Managed Backups are used to synchronize SQL Server dSources when existing SQL Server backup files cannot be made available to the Staging server, or if a third-party backup vendor is used that is not yet supported by Delphix. For more information on this functionality see [Delphix as a Backup Solution to SQL Server](#) and [Linking a dSource with SQL Server](#).

Backup compression is preferable in the following situations when:

- The default backup compression setting for the Source SQL Server instance is Disabled (0)
- The Source database does not use Transparent Data Encryption (TDE)
- The Source server has available CPU resources to perform compression

Where the compression ratio of a compressed backup exceeds 3:1, this will reduce the amount of data (by half) that must be transferred over the network to perform a backup, resulting in much faster SnapSync operations.

How to enable backup compression

If the SQL Server instance's default backup compression setting is enabled (see Microsoft's document [View or Configure the backup compression default Server Configuration Option](#)), no specific action is required. Backups will automatically be compressed in accordance with this setting.

If backups are not automatically compressed, the Delphix Engine (5.2 and later) can be configured to force compressed backups using the following steps:

- Login to the Delphix Engine's Management interface.
- Open the **Manage > Datasets** screen.
- Locate and select the dSource (using the tree on the left).
- Navigate to the **Configuration > Data Management** pane.
- Click the **Edit** (pencil) icon to modify the Validated Sync settings.

- Select the **Force Compression** checkbox, then the select the Tick icon to save the changes

### Validated Sync Configuration

The change will automatically take effect during the next scheduled Snapshot/SnapSync operation.

#### Delphix managed backups on secondary nodes of alwaysOn availability group cluster

The Always On availability groups feature is a high-availability and disaster-recovery solution that provides an enterprise-level alternative to database mirroring. Introduced in SQL Server 2012 (11.x), Always On availability groups maximizes the availability of a set of user databases for an enterprise. An *availability group* supports a failover environment for a discrete set of user databases, known as *availability databases*, that failover together. An availability group supports a set of read-write primary databases and one to eight sets of corresponding secondary databases. Optionally, secondary databases can be made available for read-only access and/or some backup operations. Some customers prefer using secondary nodes for backup to reduce the load on the primary node while some customers are OK with using the primary node. To provide more flexibility for customers using Always On availability groups with Delphix Managed backups, delphix provides an option to choose backup policy during linking of a dSource.

They can pick one of the following options that describe their backup policy as shown below.

- Primary (**default option**): Backups are taken only on the primary node.
- Secondary Only: Customers who never want to use primary for their backups must choose this option as it ensures backups never go to the primary node. If the secondary nodes are down, the backups fail but do not use primary at all.
- Secondary preferred: As the name suggests, one of the secondary nodes is used for backup. The backup will be taken on primary if none of the secondary nodes can be used for backup. So, customers who want reliable backups even if they are taken on the primary node if required should use this option.

Snapshot

## Understanding snapSync policies

SnapSync policies provide you the ability to specify how frequently the Delphix Engine takes a copy-only full backup of a source database when Delphix Managed Backups are enabled. Selecting an initial SnapSync policy is mandatory at dSource link time. However, you can change the SnapSync policy that the Delphix Engine applies to a dSource at any time by visiting the policy management screen:

1. Click **Manage**.
2. Click **Policies**.

## Policies

**SnapSync**   VDB Snapshot   Retention   VDB Refresh

How often snapshots of a source database are taken for a dSource. + SnapSync

<b>Default SnapSync</b>	🗑️ ✎
Snapshot will be taken <span style="float: right;">US/Pacific UTC -08:00</span> At 03:30 AM, only on Sunday At 03:30 AM, only on Monday ...	
This policy applies to <b>2 group(s)</b> and <b>5 dataset(s)</b> .	
▼	
<b>None</b>	🗑️ ✎
There are no schedules of this policy.	
This policy does not apply to any objects.	
▼	

### Check SnapSync Policy

For dSources that have Delphix-managed backups enabled, the current SnapSync policy will be displayed under the **SnapSync** column. The rows corresponding to dSources that do not use Delphix Managed Backups will be grayed out. Clicking the **current SnapSync policy** for a dSource will display a drop-down menu of existing SnapSync policies along with the option to create a new SnapSync policy. Selecting a SnapSync policy from this list will change the current SnapSync policy for the dSource. When creating a new policy, you will see the following screen:

## SnapSync Policy

- Policy
- Datasets
- Summary

### Policy

The schedule you set for a SnapSync policy determines when snapshots of your source database will automatically be generated. You can use structured values or cron expressions to drive the policy.

**Policy Name**

**Time Zone**

**Timeout**

Timeout in  Minute(s)

**Schedule**

**Sunday** +

Snapshots will be taken at:

↑

:

AM

↓
↑
↓

---

**Monday** +

Snapshots will be taken at:

↑

:

AM

↓
↑
↓

---

**Tuesday** +

Snapshots will be taken at:

↑
↑

### Create New SnapSync Policy

Here, you can configure the frequency with which the Delphix Engine takes backups of your source database. You can modify these schedules at any time by clicking the **Modify Policy Templates** button in the upper right-hand corner of the policy management screen.

The **Timeout** field above specifies how long a SnapSync job is allowed to run before it is terminated. If a SnapSync job exceeds its timeout window, the Delphix Engine discards the new backup and rolls back the dSource to the most recent snapshot.

Delphix managed backups on secondary nodes of SQL Server alwaysOn availability group cluster

The Always On availability groups feature is a high-availability and disaster-recovery solution that provides an enterprise-level alternative to database mirroring. Introduced in SQL Server 2012 (11.x), Always On availability groups maximizes the availability of a set of user databases for an enterprise. An *availability group* supports a failover environment for a discrete set of user databases, known as *availability databases*, that fail over together. An availability group supports a set of read-write primary databases and one to eight sets of corresponding secondary databases. Optionally, secondary databases can be made available for read-only access and/or some backup operations. Some customers prefer using secondary nodes for backup to reduce load on the primary node while some customers are OK with using primary node. To provide more flexibility for customers using Always On availability groups with Delphix Managed backups, delphix provides an option to choose backup policy during linking of dSource.

They can pick one of the following options that describe their backup policy as shown below.

- **Primary (default option):** Backups are taken only on the primary node.
- **Secondary Only:** Customers who never want to use primarily for their backups must choose this option as it ensures backups never go to the primary node. If the secondary nodes are down, the backups fail but do not use primary at all.
- **Secondary preferred:** As the name suggests, one of the secondary nodes is used for backup. The backup will be taken on primary if none of the secondary nodes can be used for backup. So, customers who want reliable backups even if they are taken on the primary node if required should use this option.

Receive side scaling for Windows staging target and targets

Enabling Receive Side Scaling (RSS) on a Windows Target and Staging Target can have a significant improvement in the overall IO throughput to the Delphix Engine and is a best practice. RSS enables network adapters to distribute the kernel-mode network processing load across multiple processor cores in multi-core computers. The distribution of this processing makes it possible to support higher network traffic loads than would be possible if only a single core were to be used.

More information on RSS can be found [here](#).

**ⓘ** Enabling RSS on the network interface will force the network service to restart and will cause a momentary loss of connectivity on that network interface

**ⓘ** Because hyper-threaded CPUs on the same core processor share the same execution engine, the effect is not the same as having multiple core processors. For this reason, RSS does not use hyper-threaded processors.

Steps to implement RSS on Windows

1. From Server Manager/Local Server/Network Connections select the NIC that Delphix will be connecting to.

2. Select Properties and then Configure.

3. From the Property menu on the left, select **Receive Side Scaling**, confirm that it is set to **Enabled**, and select **OK** to close each of the open windows.

## Validated sync environment

This topic describes additional requirements for SQL Server environments that will be used as targets for validated sync. You must configure a staging (Validated Sync) environment as a target, with a few additional requirements.

### Requirements for SQL server validated sync target environments

Each SQL Server target environment used for validated sync must meet these requirements:

- Only standalone target environments can be used as validated sync target environments. Windows Failover Cluster target environments and SQL Server Failover Cluster instances cannot be used.
- The SQL Server instance must be the same version as the instance hosting the source database. For more information about compatibility between different versions of SQL Server, see [SQL Server Support Matrix](#).
- The owner of the SQL Server instances on the target environment that are used for the staging databases must have SMB read access to the location containing the backup images of the source databases.
- If the source database is backed up with third-party backup software like LiteSpeed or Red Gate SQL Backup Pro, you must install the backup software on both the source and the validated sync environment. For backup software compatibility requirements, see [SQL Server Support Matrix](#).

### Add the validated sync environment

The order is important. Add the validated sync environment as the first step in setting up the SQL Server topology.

1. From the machine that you want to use as a target, start a browser session and connect to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next to **Environments**, click the **Actions** menu and select **Add Environment**.
5. In the **Add Environment** wizard Host and Server tab, select:
  - a. Host OS: **Windows**
  - b. Host Type: **Target**.
  - c. Server Type: **Standalone**.
6. Click **Next**.
7. In the Environment Settings tab click the download link for the **Delphix Connector Installer**. The Delphix Connector will download to your local machine.
8. On the Windows machine that you want to use as a target, run the Delphix Connector installer. Click **Next** to advance through each of the installation wizard screens. The installer will only run on 64-bit Windows systems. 32-bit systems are not supported.
  - a. For **Connector Configuration**, make sure there is no firewall in your environment blocking traffic to the port on the target environment that the Delphix Connector service will listen to.
  - b. For **Select Installation Folder**, either accept the default folder, or click **Browse** to select another.
  - c. Click **Next** on the installer final 'Confirm Installation' dialog to complete the installation process and then **Close** to exit the Delphix Connector Install Program.
9. Return to the Delphix Management application.
10. Enter the **Environment Name, Host Address, Delphix Connector Port, OS Username, and OS Password** for the target environment.
11. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
12. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
13. Click **Submit**.

As the new environment is added, you will see two jobs running in the **Delphix Admin Job History**, one to **Create and Discover** an environment, and another to **Create** an environment. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel.

## Changing the hostname (IP address) or IQN of a SQL Server target or staging host

This topic describes how to change the hostname (IP address) or iSCSI Qualified Name (IQN) of a Windows Target or Staging host.

By default, Windows servers generate an IQN based on the hostname assigned to it. Changing the hostname will change the host IQN as well. Because the Delphix Engine exports storage for dSources and VDBs to Windows hosts using iSCSI, changes to the Windows hostname must be made according to the following procedure. If you have set a non-default IQN on a Windows Target or Staging host, and want to change that IQN, you must follow these procedures.

- Changing the hostname or IQN of a Windows target or staging server requires that you modify the iSCSI Initiator configuration on the Windows host. Doing so incorrectly can cause failures in dSources, VDBs, or non-Delphix users of iSCSI on the Windows host.

The instructions in this topic describe how to change the IQN using the `iscsicli` command-line utility. Because many people are less familiar with the `iscsicli` utility, the instructions also include information for using the iSCSI Initiator graphical user interface.

Failing to carefully follow the steps below in sequence can cause availability issues for your dSources and VDBs. If you have questions about the following instructions, [please contact Delphix Support for help](#).

1. Disable the dSources.
2. Disable the VDBs. **Note:**  
If your Windows server has dSources or VDBs from more than one Delphix Engine, you will need to disable the dSources and VDBs on each Delphix Engine.
3. Remove any remaining persistent volumes from the Windows server. From the Server Manager\Tools\iSCSI **Initiator** configuration tool, use the options available in the **Volumes and Devices** tab. or, Follow these steps to use the `iscsicli` command-line utility: List the persistent volumes.

```
PS C:\> iscsicli reportpersistentdevices
Microsoft iSCSI Initiator Version 6.1 Build 7601
Persistent Volumes
"\\?\storage#volume#{bb38add1-d03f-11e1-8767-005056b37fe6}
#0000000008010000#{53f5630d-b6bf-11d0-94f2-00a0c91efb8b}"
"C:\Program Files\Delphix\DelphixConnector\564d6fbb-df9d-e90b-00f1-
da37b17011d3-staging-15\ARCHIVE\"
[...]
```

The operation completed successfully.

- a. Volumes with a "normal" path correspond to mounted volumes. For example, `C:\Program Files\Delphix` is a normal path. If you see any normal paths in the output, be sure you have disabled all of the VDBs and dSources.
- b. Volumes with a path beginning `\\?\` correspond to unmounted persistent volumes. Remove each of them:

```
PS C:\> iscsicli RemovePersistentDevice
"\\?\storage#volume#{bb38add1-d03f-11e1-8767-005056b37fe6}
#0000000008010000#{53f5630d-b6bf-11d0-94f2-00a0c91efb8b}"
```

- c. Alternatively, if all of the persistent devices are for unmounted volumes, you can remove them all at once with this command:

```
PS C:\> iscsicli clearpersistentdevices
```

4. Remove all of the persistent targets. From the Server Manager\Tools\iSCSI Initiator configuration tool, use the options available in the **Favorite Targets** tab. or, Follow these steps to use iscsicli command-line utility:
- List persistent targets:

```
PS C:\> iscsicli ListPersistentTargets
```

- Remove the appropriate persistent targets. Below is sample output listing the persistent targets:

```
PS C:\> iscsicli ListPersistentTargets
[...]
Target Name           : iqn.2008-07.com.delphix:02:02843619-12c4-e4d2-8
041-f5c56a647bc2
Address and Socket    : 10.43.5.45 3260
Session Type         : Data
Initiator Name       : Root\ISCSIPRT\0000_0
Port Number          : <Any Port>
Security Flags       : 0x0
Version              : 0
Information Specified: 0x20
Login Flags          : 0x0
Username             :
[...]
```

Warning: Misleading Help for RemovePersistentTarget Command

The help for iscsicli `RemovePersistentTarget` is misleading:

```
iscsicli RemovePersistentTarget <Initiator Name> <TargetName>
                                <Port Number>
                                <Target Portal Address>
                                <Target Portal Socket>
```

<Initiator Name> and <Target Name> show up in the listing and should be taken directly from there. <Port Number> can be taken from the listing output, but a \* should be used if <Any Port> is listed. <Target Portal Address> and <Target Portal Socket> are shortened to `Address` and `Socket` in the `ListPersistentTargets` output. The term `Socket` in both places is what is more typically referred to as a `port`.

- Use the `RemovePersistentTarget` command to remove the target, as shown in this example:

```
PS C:\> iscsicli RemovePersistentTarget Root\ISCSIPRT\0000_0 iqn.2008-07.c
om.delphix:02:02843619-12c4-e4d2-8041-f5c56a647bc2 * 10.43.5.45 3260
```

5. Log out of any sessions.

From the Server Manager\Tools\iSCSI Initiator configuration tool, use the options available in the **Targets** tab to log out. Selected a connected session under **Discovered Targets**, and then click **Disconnect**. or, Follow these steps to use the iscsicli command-line utility: List the sessions.

```
PS C:\> iscsicli sessionlist
Session Id : fffffa8003fb0018-4000013700000001
Initiator Node Name : iqn.1991-05.com.microsoft:10-43-1-200.ad.delphix.com
Target Node Name : (null)
Target Name : iqn.2008-07.com.delphix:02:02843619-12c4-e4d2-8041-f5c56a647bc2
[...]
```

- a. Log out from the target.

```
PS C:\> iscsicli logouttarget fffffa8003fb0018-4000013700000001
```

6. Change the hostname (IP address) or IQN in the Delphix engine.
  - a. If you are changing the hostname, follow the instructions in the [Microsoft TechNet](#) article "Rename the Computer."
 

**Note** : Note that if the computer is on a domain, you will need a domain administrator to perform the rename or re-add the computer to the domain depending on the version of Windows it is running.
  - b. To use the Delphix Setup application, go to **Manage** → **Environments** screen and select the Target host. To modify the Host Address for the environment, use the Edit (Pencil) icon next to the **Attributes** panel. Update the Host Address to reflect the new IP address, and then use the **Save (Tick)** icon to confirm the change. This will automatically trigger an action to Refresh the Environment. The refresh process includes steps to configure the iSCSI Target and verify that it is reachable.
  - c. If you are changing the IQN only, change it through the Microsoft iSCSI Initiator GUI following the instructions in the [Microsoft iSCSI User Guide](#).
7. Wait for the computer to finish rebooting.
8. Verify the new IQN in the iSCSI initiator.
 

**Note** : If you are using the default IQN and have changed the hostname (IP address), the IQN should include the new hostname.
9. Refresh the environment on the Delphix Engine.
10. Re-enable the dSources.
11. Re-enable the VDBs.
12. Using the iscsi cli command-line utility, verify that the sessions on the Windows server are using the new IQN.

```
PS C:\> iscsicli sessionlist
Microsoft iSCSI Initiator Version 6.1 Build 7601

Total of 1 sessions

Session Id : fffffa8003f77018-4000013700000004
Initiator Node Name : <NEW IQN>
[...]
```

## Linking data sources and syncing data with SQL Server

Creating a dSource will ingest data from the source and create a dSource on the engine. The dSource is an object that the Continuous Data Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools.

This section covers the following topics:

- [Linking a dSource from a SQL server: an overview](#)
- [Linking data sources with SQL server](#)
- [Staging push implementation for SQL server](#)
- [Data management settings for SQL server data sources](#)
- [Additional SQL server dSource topics](#)

## Linking a dSource from a SQL Server: An overview

When linking a dSource from a SQL Server source database, Delphix offers several different methods of capturing backup information:

- Delphix Managed Backups, where the Delphix Engine schedules and initiates the backups from the source database, and captures them
- SQL Server Managed Backups, where the SQL Server source database schedules and initiates backups and the Delphix Engine captures them
  - Full backups
  - Full or differential backups
  - Transaction log backups (with LogSync disabled)
  - Transaction log backups (with LogSync enabled)

Delphix Managed Backups are conceptually a lot simpler to explain, but they can be considered less desirable because they might be viewed as intrusive. SQL Server Managed Backups are explained in two sections:

- the initial load of the dSource from the source database
- subsequently keeping the dSource synchronized with the source database.

Below is a brief explanation of how these three different modes of operation work.

### Delphix managed backup mode

When the **Enabled** checkbox for Delphix Managed Backups is selected, the Delphix Engine will initiate a COPY\_ONLY full backup of the source database for the initial load of the dSource. Thereafter, the Delphix Engine will initiate COPY\_ONLY full backups of the source database using the schedule specified by the selected SnapSync Policy. If SnapSync Policy is set to None, the Delphix Engine will not automatically initiate COPY\_ONLY backups, but you can initiate them manually using the snapshot (camera) icon.

When the **Force Compression** checkbox for Delphix Managed Backups is selected and the backups are not compressed, the Delphix Engine will take a compressed copy-only full backup of the source database and this will take effect during the next scheduled Snapshot or SnapSync operation.

- COPY\_ONLY backup files are written to the Delphix storage that has been mounted on the staging server. Delphix does not require space on the source or staging servers to hold the backup files.

You must also select the Staging Environment and the SQL Server instance onto which the backups will be restored.

### SQL server managed backup modes

#### Initial load of the dSource

When the Delphix Managed Backups option is left unchecked (*default*), the Delphix Engine will initiate a backup only when the user selects to initiate a COPY\_ONLY full backup that the Delphix Engine will use to keep the dSource in sync with the source database.

For the initial load of the dSource, you can choose one of the following:

- have the Delphix Engine initiate a COPY\_ONLY full backup
- use the most-recent existing full or differential backup (*default*)
- use a specific existing full or differential backup identified by its `backup_set_uuid`

- Simple Recovery Model

If the source database is using a simple recovery model, using a new full COPY\_ONLY backup initiated by the Delphix Engine is not supported for the initial load of a dSource.

After the initial load, you need to select the Backup Paths and tell the Delphix Engine where to look for backups of the source database.

- If **Autodiscover** is selected, the exact path used to take the backup from the source database will be determined by querying by the source database instance. If this option is used, the Delphix Engine should take backups to a UNC path (Windows file share) so that they are accessible to the Staging Server.
- If custom paths are specified, the Delphix Engine will query the source database instance, identify the filename of the source backup, and then recursively search the specified Backup Paths for this filename. These paths should also be UNC paths (Windows file share) which are accessible to the Staging Server.

The path used to restore backups must be readable by the Windows server hosting the staging instance, using the staging environment's configured Environment User.

The Delphix Engine supports source database backups that SQL Server creates natively, as well as backups created by Quest/Netvault LiteSpeed, Red Gate SQL Backup Pro, Veritas NetBackup, and Commvault. For more information, see the topic [SQL Server Support Matrix](#).

Once you have decided how the dSource will be initially loaded, select the staging environment and the SQL Server instance onto which the backups will be restored. NetBackup and Commvault backups are not on local storage and therefore the Backup Paths will just be ignored. See [Linking a dSource from a NetBackup SQL Server Backup](#) and [Linking a dSource from a Commvault SQL Server Backup](#) for more information.

 The staging instance opens the backup file for reading and may hold a lock on it when restoring the backup on the staging database. A new source database backup, initiated with the **Append to the existing backup set** option, may fail as SQL Server will not be able to open the locked backup file to append a new backup to it.

Keeping the dSource synchronized with the source database

Next, specify how the Delphix Engine will capture subsequent backups of the source database.

The selected Validated Sync mode determines how often the Delphix Engine will check for new backups, and which type of backups it will check for. You can always force synchronization with the source database by enabling **Validated Sync Mode** from the **Data Management** tab available under the **Configuration** tab for the selected dSource.

Validated sync and logSync

When you link a source database into the Delphix Engine, a staging database will still be required if the Validated Sync is not enabled, as described in [Overview of Setting Up SQL Server Environments](#). In this process, the Delphix Engine continuously monitors the source database for new full and differential backups if the source database is using a **simple** recovery model, or transaction log backups if using a **full** recovery model. This will also depend on the selected backup mode. When it detects a new backup, it restores that backup to the staging database with the storage residing in Delphix. The result is a TimeFlow with consistent points from which you can provision a VDB, also known as snapshots.

Snapshots accumulate over time. To view a snapshot:

1. From the **Datasets** panel, click the **group** containing the dSource.
2. Select **dSource**.
3. Click the **TimeFlow** tab.

Each snapshot is displayed and includes some information about the captured database along with Snapshot database change number (SCN for Oracle and LSN for SQL Server). You can scroll through these cards to select the one you want, or you can enter a date and time to search for a specific snapshot.

Summary of validated sync modes

This table summarizes each mode of Validated Sync, displaying how often the Delphix Engine will poll to check for new backup files when it creates snapshots for the dSource, and whether point-in-time restores for provisioning and refreshing virtual databases (VDBs) is possible or not.

Validated Sync Mode	Polling Interval	Snapshot for each FULL backup	Snapshot for each DIFF backup	Snapshot for each TLOG backup	Allows Point-in-time Restores	Notes
<b>Delphix Managed Backups</b>	N/A	N	N	N	N	Takes COPY_ONLY full backups according to SnapSync schedule. For more information on this option, see <a href="#">Delphix as a Backup Solution to SQL Server</a> .
<b>Transaction log backups (LogSync DISABLED)</b>	1-minute	N	N	Y	N	Log backups are not collected if: <ul style="list-style-type: none"> <li>• There are gaps in the sequence of log backups (a break in the "log chain")</li> <li>• The available log backups do not include any changes since the last successful Delphix snapshot</li> </ul>
<b>Transaction log backups (LogSync ENABLED)</b>	1-minute	N	N	Y	Y	Log files consume additional space on the Delphix Engine and are managed according to the defined retention policy for logs. For NetBackup and Commvault backups, Point-in-time restores are not supported.

<b>Full or differential backups</b>	1-minute	Y	Y	N	N	
<b>Full backups</b>	1-minute	Y	N	N	N	
<b>None</b>	Manual only	N	N	N	N	Only retrieves backups when you initiate a manual snapshot.

**i Timeflow cards**

The Delphix Engine will create a Timeflow card for each backup it restores to the staging server. For example:

- A database in Full backups Validated Sync mode, and daily backup configured on the dSource, would receive one Timeflow card per day
- A database in Full or differential backups sync mode, with one daily backup and two differential backups per day, would receive three Timeflow cards per day
- A database in Transaction log backups sync mode, with a log backup every 15 minutes, would receive 96 TimeFlow cards per day

## Linking data sources with SQL Server

Linking a dSource will ingest data from the source and create a dSource object on the engine. The dSource is an object that the Continuous Data Engine uses to create and update virtual copies of your database. As a virtualized representation of your source data, it cannot be managed, manipulated, or examined by database tools.

For an overview of all dSource related actions, please [Managing Data Sources and Syncing Data](#).

When linking a dSource from a SQL Server source database, Delphix offers several different methods of capturing backup information:

- SQL Server Managed Backups, where the SQL Server source database schedules and initiates backups and the Delphix Engine captures them
  - Full backups
  - Full or differential backups
  - Transaction log backups (with LogSync disabled)
  - Transaction log backups (with LogSync enabled)
- Delphix Managed Backups, where the Delphix Engine schedules and initiates the backups from the source database, and captures them

### Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Click the plus icon and select **Add dSource**.
4. In the **Add dSource** wizard, select the source database with the correct environment user-specified.
5. Select user type for source database authentication and enter the login credentials. Enter username and password for Database user or Domain (Windows) user. For Environment User, select a source environment user from the dropdown list and click **Next**.
6. Enter a name and select a group for your dSource.  
Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. Select the **Data Management** settings needed. For more information, [Data Management Settings for SQL Server Data Sources](#).
8. Select the Staging environment and SQL Instance that will be used to manage the staging database used for validated sync of the dSource.
9. Select any policies for the new dSource.
10. Enter any scripts that should be run on the **Hooks** page.
11. Review the dSource Configuration and Data Management information, and then click **Submit**.

## Staging push implementation for SQL Server

This topic provides implementation details of Staging Push for SQL Server. Staging Push eliminates the need of accessing the customer's production environment and hence the dependency on it. For end-users with a wide variety of architectural requirements such as an unsupported backup appliance, complex ingestion requirements, and supporting alternate replication methods, Staging Push increases flexibility by ensuring that Delphix can work with most of these unique requirements while maintaining Delphix standard product support.

Staging Push gives end-users control over some Staging DB processes so that the nuanced, staging-based ingestion can be orchestrated externally. It will give control of the staging database to the end-user to pull from any backup provider (as a part of this, you'll be responsible for keeping the Staging DB in sync with the production database). Staging database files will be stored on Delphix Storage. Delphix will still be the one snapshotting the underlying data files, and gathering the metadata required to provision from the snapshot.

The below steps show how to create a dSource using the Staging Push mechanism.

### Procedure

1. Login to the **Delphix Management** application.
2. Navigate to **Manage > Datasets**.
3. Click the plus icon and select **Add dSource**.
4. On the Preparation tab, click **Next**.
5. From the **dSource Type** tab, select the **Staging Push** option and click **Next**.
6. From the **dSource Configuration** tab, enter the following dSource configurations, also shown in the screenshot below, and click **Next**. **dSource Name** - This name will be available on the Delphix Engine interface. **Database Name** - This is the name of the staging database that is created on the staging host after linking. It is suggested to use the word "staging" while assigning a name to the staging database as this will help to distinguish it from other end-user databases.

## dSource Configuration

Target a group from your Datalist or create a new group

### dSource Name

### Database Name ?

### Target Group

[Add Dataset Group](#)

### Notes

7. From the **Data Management** tab, select the staging environment and repository details. The staging environment is where the staging database will be hosted and a repository is a container for the SourceConfigs objects. Each environment in Delphix can contain any number of SQL Server instances and each SQL Server instance can contain any number of databases.
8. Select any policy for the new dSource. SnapSync policy is used as a default policy for taking snapshots. For more details on SnapSync policy, see [Policies for Scheduled Jobs](#).
9. Enter any script that should be run on the **Hooks** page. For staging push dSources, a restore backup script can be added as a part of the hooks script to automate backup restore. Refer to the below section for more details.
10. Review the Staging Push dSource Configuration and Data Management information, and then click **Submit**.

### Restoring backups

After linking and before taking a snapshot, if the user wants to align the staging database with the source database automatically they can do so by providing the restore script in the hook, as shown below. They can also manually restore a database backup on the staging host.

First backup restoration needs to be a full backup with the REPLACE keyword.

## Prerequisites

When restoring the backup, make sure that all the database files are present at the mounting location.

The mounting location is available as **Mount Base** under the **Configuration** tab of the newly created dSource.

The screenshot shows the Dsource Configuration tab with the following details:

Source	Policies	Masking	Hooks
<b>STAGING DATABASE</b> <b>Name</b> Dsource1 <b>Size</b> 200.00MB <b>Version</b> MS Sql 13.2.5233.0 <b>Mount Base</b> C:\Program Files\Delphix\DelphixConnector\564d18cc-f930-62d6-3bff-b86b9dbc959f-staging-8 <b>Recovery Model</b> FULL		<b>STAGING ENVIRONMENT</b> <b>Name</b> sg-win2019tgt <b>OS</b> Windows (Windows) <b>Timezone</b> America/Los_Angeles,PST-0800 <b>Repository</b> SQL2016 <b>User</b> qa-ad\delphix	

## Procedure

Manually restore a backup on the staging host or provide the restore script in the hook script. A sample pre-sync hook for native backup is shown below. It also lists the following keywords.

- NORECOVERY - Keeps the database in restoring state.
- REPLACE - Overwrites existing database created during linking with whichever source database that is in the backup set and is getting restored.
- MOVE - Restores the data and log file to the specified locations.
- BACKUP\_FILE\_LOCATION - The location of the backup file of the source database from where the backup is restored and it should be accessible from the staging host. For example, \\10-43-89-18\Backup\sp.bak.

Sample hook to illustrate restore script usage for restoring backups

```
#
# Copyright (c) 2022 by Delphix. All rights reserved.
#
#Set-Variable UTF8_CODEPAGE 65001 -option readonly
```

```

#Set-Variable UTF8_ENCODING "System.Text.UTF8Encoding" -option readonly
# Uncomment the following log to turn on debugging
# Set-PSDebug -Trace 2;
$DSOURCE_HOST = $env:STAGING_INSTANCE_HOST
$DSOURCE_PORT = $env:STAGING_INSTANCE_PORT
$DSOURCE_INSTANCE = $env:STAGING_INSTANCE_NAME
$CONNECT_STRING = "$DSOURCE_HOST\$DSOURCE_INSTANCE,$DSOURCE_PORT"
$DSOURCE_NAME = "$env:STAGING_DATABASE_NAME"
$DataDbFilePath = "$env:STAGING_MOUNT_BASE"
$SQL_SCRIPT= "RESTORE DATABASE $DSOURCE_NAME FROM DISK = '\\BACKUP_FILE_LOCATION'
WITH NORECOVERY, REPLACE, MOVE N'<Source_db_name>' TO '$DataDbFilePath\DATA\db\
$DSOURCE_NAME.mdf', MOVE N'<Source_db_name>_log' TO '$DataDbFilePath\DATA\db\" +
$DSOURCE_NAME + "_log.ldf"
function die {
    Write-Error "Error: $($args[0])"

    # run exit handler, if defined
    if (Get-Command -type Function -name atExit 2> $null) {
        atExit
    }
    exit 1
}

function verifySuccess {
    if (!$?) {
        die "$($args[0])"
    }
}

### Restore database.

echo $SQL_SCRIPT
Sqlcmd -b -S $CONNECT_STRING -U sa -P <PWD> -Q $SQL_SCRIPT
verifySuccess "Failed to restore backup"

# Uncomment the following line to turn off debugging
# Set-PSDebug -Trace 0;

exit 0

```

## Snapshot

The first snapshot is created as a part of dSource creation and contains data and log files within the Delphix created mount point.

-  The first snapshot created is of an empty database and does not contain any source database's data. (Unless a source backup was restored via a pre-sync hook. In that case, the initial snapshot will be that of source backup and won't be empty).

## Prerequisites

- The database should be present on the staging host.

- The DATA directory should be mounted.
- The DB files should be present on Delphix mounted DB directory. For example, `C:\Program Files\Delphix\DelphixConnector\ec2197b2-e0c6-48d2-bd14-265e6fa9b5ab-staging-1\DATA\db`
- The database should be in Restoring state.
- No other restore operation should be in progress on the staging database.

#### SnapSync criteria

- Delphix tries to fetch the last restored backup. If no backup is found, the snapshot is skipped with a warning.
- If a snapshot already exists for the backup in the current timeflow, the snapshot is skipped with a warning.

Snapshots display the Staging Host timezone, as opposed to Linked dSources, where snapshots display the Source Host timezone. Here, the Staging timezone is displayed for Staging Push as we don't have the Source host to fetch the timezone information. This functioning might change in the future.

Perform the following steps to take a snapshot:

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource created using the Staging Push mechanism to Snapshot.
4. Click the **Camera** icon.
5. From the Snapshot dialog box, select **Yes**.
6. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the Snapshot you just created. You can now proceed to provision the VDB using the snapshot.

#### Disabling and enabling the dSource

When a disabled dSource is later enabled, it will resume communication and incremental data updates from the staging database according to the original policies and data management configurations that you set.

#### Procedure

Disabling a dSource will stop further operations on the Delphix Engine related to the staging dSource.

1. Login to the Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **dSource** you want to disable.
5. In the upper right-hand corner, from the **Actions** menu (...) select **Disable**.
6. In the Disable dialog select **Disable**.

When you are ready to enable the dSource again, from the Actions menu (...) select **Enable**, and the dSource will continue to function as it did previously.

Keep a note of the following:

- During enable, if there exists a database with the same staging database name as the user entered and it is not Delphix managed, or if it is but Delphix Engine is unable to drop it, the enable operation will not be terminated.
- Storage mounting will be attempted for the dSource and a new job event `SKIP_ATTACH_OPERATION` will be displayed. This means the job is updated with a warning and attach operation is skipped. The enable operation will be marked as successful.  
**Note** : Customers can drop the database that is outside Delphix or that wasn't dropped and try again the disable/enable option.

- Delphix will attempt to mount the staging database's storage during the enable job. Even if the attach job fails, the storage will remain mounted (if Delphix was able to successfully mount it) and the enable job will be marked as successful.

#### Unlink(Detach)/link(attach) a dSource

Each dSource contains metadata that associates it with the staging database, as well as the data it has ingested from the staging database in the form of snapshots up to that point. It is possible to detach, or unlink, a dSource from its staging database.

- A detached dSources can still be used to provision a virtual database (VDB).
- You can re-link the staging push dSource with a different staging database name than before. In that case, the staging database will be created with the new name provided. However, DB file names will remain the same as before.
- Delphix Engine supports converting existing Linked dSource to Staging push dSource and vice versa.

#### Unlinking or detaching a dSource

1. Login to the **Delphix Admin** application.
2. Click **Manage**.
3. Select **My Datasets**.
4. Select the **database** you want to unlink.
5. From the Actions ... tab, click **Unlink**.
6. Click **Yes** to confirm.

#### Attaching a previously detached dSource

1. Login to the **Delphix Admin** application.
2. Click **Manage**.
3. Select **My Datasets**.
4. Select the **database** you want to link.
5. From the Actions ... tab, click **Link dSource**. Select **Staging Push** and enter **staging database Name**, select **Staging Environment** and **Staging Repository**.

## Link dSource ✕

---

**dSource Type**

Linked dSource  
Staging Linked to a source database

Staging Push  
Customer managed staging database

**Staging Database Name**

**Staging Environment**

**Staging Repository**

---

6. Click **Link to confirm**.

#### Limitations

1. Restore backups fails on staging database due to mount issues. When a critical threshold is enforced due to Delphix storage and later resumed successfully, a transactional log will not be applicable on the staging database directly. A generic warning will be displayed for the resume job only for staging push dSources on the Delphix interface that after the mount, the user might face issues in restoring a transaction log. SQL server error when restoring the Tlog after resume:

```
Msg 4320, Level 16, State 3, Line 13
```

The file " SourceDB4\_log " was not fully restored by a database or file restore. The entire file must be successfully restored before applying this backup set.

Msg 3013, Level 16, State 1, Line 13

RESTORE LOG is terminating abnormally.

**RESOLUTION:** Full or differential backup will be successfully restored.

2. Attach operation fails during the Enable operation.

If the attach operation fails for staging push dSource, any exception is consumed and the enable operation is marked as a success.

For example, if DB files were changed for the staging database but a snapshot was not taken on the Delphix engine and disable was performed directly, the enable will succeed with an attach failure that will be shown as a warning. The previous DB files will be available on the mount path.

**RESOLUTION:** The customer can apply a full restore at this point to bring the database in restoring mode before trying to run a sync.

3. Point-in-Time provisioning is not supported.
4. The sub-directory structure for DB files is not supported.

For example, if a staging database is restored with DB files inside another folder within the DB directory ( C:

\Program Files\Delphix\DelphixConnector\ec2197b2-e0c6-48d2-

bd14-265e6fa9b5ab-staging-1\DATA\db\folder1\sp.mdf, C:\Program

Files\Delphix\DelphixConnector\ec2197b2-e0c6-48d2-bd14-265e6fa9b5ab-

staging-1\DATA\db\folder1\folder2\sp\_log.ldf ), then operations such as to enable, relink, VDB provisioning, and export will fail.

5. The validated sync process is not supported for Staging Push dSources.
6. Staging database states other than Restoring such as ReadOnly, StandBy, and Online are not supported. If a database is in any of these unsupported states, dSource will go into the Cannot Monitor state on the Delphix Engine interface, and Sync operation will fail.

## Data management settings for SQL Server data sources

Each dSource has its own data management settings, which can be configured during the linking workflow as well as in the configuration page for that dSource.

You can configure data management settings to improve overall performance and match the needs of your specific server and data environment.

The following settings are available for SQL Server data sources:

Setting	Explanation
Managed Backups	When enabled, the Delphix engine will take full backups of the database, per the dSource's SnapSync policy, and validated sync will be disabled. Existing backups cannot be used to synchronize the dSource when backups are managed by Delphix.
Recovery Model	The current recovery model of the source database. Three recovery models exist simple, full, and bulk-logged. This is not configurable from Delphix but can be changed within the source's database settings.
Initial Load	<ol style="list-style-type: none"> <li>1. Delphix will take a copy-only full backup of your source database.</li> <li>2. Use the most recent full or differential backup (default).</li> <li>3. Use a specific full or differential backup.</li> </ol>
Backup Paths	<p>These are the locations where Delphix will be looking for backups for ingestion.</p> <p>Select Autodiscover to have the Delphix Engine automatically locate the backups by querying the msdb database in the SQL instance.</p> <p>Otherwise, for each path, please specify the top level of a particular backup path since the Delphix Engine will recursively search for the backup file in all subdirectories beneath the specified path.</p>
Validated Sync Mode	<p>Determines the types of backups validated sync will use to generate snapshots.</p> <ol style="list-style-type: none"> <li>1. Transaction log backups. <ol style="list-style-type: none"> <li>a. LogSync adds log files from the source database to the dSource, allowing you to provision a virtual database (VDB) from a specific point in time or LSN for SQL Server databases.</li> </ol> </li> <li>2. Full or Differential backups.</li> <li>3. Full backups.</li> <li>4. None.</li> </ol>
Staging Environment	This environment will host the staging database used for validated sync.

<b>Setting</b>	<b>Explanation</b>
Repository	A repository is a container for the SourceConfigs objects. Each environment can contain any number of repositories, and repositories can contain any number of source configurations. A repository typically corresponds to a database installation. Whereas source configurations typically correspond to the databases.
Encryption Key	The encryption key to be used when restoring encrypted backups. If the source database is backed up using LiteSpeed or RedGate with password-protected encryption, you can supply the encryption key that the Delphix Engine should use to restore those backups.
NetBackup Ingestion	Enables ingestion from a NetBackup source.
Commvault Ingestion	Enables ingestion from a Commvault source.

## Additional SQL Server dSource topics

This section covers the following topics:

- [Changing the staging target environment for a SQL Server dSource](#)
- [Upgrading a dSource after a SQL Server upgrade](#)
- [Linking a dSource from a commvault SQL Server backup](#)
- [Linking a dSource from a netBackup SQL Server backup](#)
- [Restoring SQL backups stored in Azure cloud storage](#)
- [Working with SQL Server snapshots](#)
- [Detaching and re-attaching SQL Server dSources](#)

## Changing the staging target environment for a SQL Server dSource

This topic describes how to change the staging target environment for a SQL Server dSource.

### Prerequisites

The dSource for the staging database must be disabled before you can change the staging target environment. Follow the steps in *Enabling and Disabling SQL Server dSources* in [Managing Data Sources and Syncing Data](#) to disable the dSource.

### Procedure

1. Click **Manage**.
2. Select **Datasets**.
3. Select the **dSource** for which you want to change the staging target environment.
4. Click the **Configuration** tab to view the **Staging Environment**.
5. Click the **Pencil** icon next to **Staging Environment**.
6. Edit the target server and the SQL Server instance on the server to use for staging.
7. Click the **Check** icon to save your changes.

## Upgrading a dSource after a SQL Server upgrade

This topic describes how to upgrade dSources after a SQL Server database upgrade.

There are two ways to upgrade a Source database:

- Perform an Upgrade installation of SQL Server, upgrading the Source and Staging SQL Server instances in-place
- Perform a fresh installation of the new SQL Server version, and migrating the databases to the new instance

The steps required to support this in the Delphix Engine are different depending on method chosen. The required steps are outlined in the sections below.

### In-place SQL Server upgrade

1. **Disable** all dSources on the instance being upgraded
2. Following Microsoft's procedures, perform an upgrade of the Source SQL Server instance
3. Following Microsoft's procedures, perform an upgrade of the Staging SQL Server instance to the same version as the Source
4. Refresh the Source and Staging environments in the GUI
5. **Enable** the dSources being upgraded

### Migrate databases to newer instance

#### Prerequisites for database migration

- Record the configuration data for each dSource being upgraded, including the Database User, Database Password (if applicable), and Validated Sync configuration. This will be needed to re-link the dSource.
- Following Microsoft's procedures, install a new Source SQL Server instance with the new SQL Server version.
- Ensure that a Staging SQL Server instance is available, running the same SQL Server version as the new Source SQL Server instance.
- **Add** or **Refresh** the Environment containing the new SQL Server instance(s), using the steps in [Adding a SQL Server Source Environment](#) and [Adding a SQL Server Standalone Target Environment](#).

 The refresh/rediscover operations do not affect the operations of any dSources or VDBs on the environment.

#### Migration steps

1. Navigate to the **Manage** → **Datasets** screen.
2. For each dSource being upgraded:
  - a. Select **Unlink dSource** from the **Actions menu (...)**
3. Following Microsoft's procedures, migrate the Source database to the new Source SQL Server instance.
4. Commence a new **Full** database backup of each upgraded Source database
5. From the **Manage** → **Environments** screen, **Refresh** the new Source Environment. The migrated databases should be detected and visible from the Environment's **Databases** tab.
6. Navigate to the **Manage** → **Datasets** screen.
7. For each dSource that was upgraded:
  - a. Select **Link dSource** from the **Actions menu (...)**
  - b. Locate the upgraded Source database using the Source Environment, **Installation and Database** drop-down boxes
  - c. Select a compatible Staging Environment and Staging Repository
  - d. Configure the **Database Authentication** using values that are appropriate for the new Source database
  - e. Click **Link** to begin linking the dSource

- f. Reconfigure any dSource settings using the dataset's **Configuration** tab
- g. Use the **Snapshot** button to take a snapshot using the upgraded database backup

## Linking a dSource from a commvault SQL Server backup

### Customer requirements:

- Delphix currently supports Commvault v11. The version of Commvault SQL Agent on the staging environment must be the same as that on the source.
- The TCP port 8415 must be open from the staging host to the Delphix Engine.
- If the dSource is backed up with Commvault, the source and staging environments must each have the SQL Agent installed.
- Both SQL Agents (on source and staging) should be registered with Commvault Server mentioned during linking.
- The install path's 'Base' directory of Commvault SQL Server Agent on the staging host, must be part of the PATH environment variable as we need to access the Commvault CLI. This is typically located at <Commvault install path>\Base.
  - There are two PATH environment variables. One is for the current logged in user and the other is a global System variable. Since the Delphix Connector runs under the "Network Service" account and spawns the Commvault commands, changes need to be done to the System variable as well.
  - After the Commvault binaries are added to both the system and user PATH environment variables, the Delphix Connector service must be restarted in order for the new process to reflect the changes made to the PATH environment variable.
  - After making the changes to the PATH, login as the Delphix operating system user and try running "qlogin -sso -gt" to confirm the user can execute Commvault commands and authenticate to the Commvault server.
- Since SSO is used from Commvault CLI to login to the CommServe server from the staging environment, SSO should be enabled.
- Active Directory domain should be configured and configured staging environment user should be given required permissions to restore the database on staging client.
- In the CommServe server, the staging client should be configured with a user who has required permissions to restore the database on the staging environment. User account configuration can be done as explained in Commvault documentation at [User Account Configuration for the SQL Server Agent](#).
- Only transaction logs, incremental, and database full backups are currently supported.

### Linking with commvault backups:

To link a dSource and use Commvault, follow the steps to add the environments as earlier, and make sure all the requirements listed above are met. Going through the linking wizard on the **Data Management** page, select **Show advanced**.

## Add dSource

We validate whether the source and staging clients exist in the CommServe server and the Commvault SQL Agent on staging client is registered to the CommServe server. To run the validation commands following login command with SSO option is used to login into CommServe Server:

```
qllogin -sso -gt
```

#### LogSync for SQL server dSources

Logsync (point-in-time provisioning) is currently not supported for Commvault transaction logs. However, LogSync can still be enabled if Commvault ingestion is enabled. LogSync for backups taken with other backup providers that support LogSync will work as before.

#### Enabling commvault for previously created dSources

On an already created dSource go to **Configure > Data Management** and click edit (pencil button). Enable Commvault Ingestion and add all the configuration as necessary.

Linking an availability group database with commvault

Linking with an Availability Group (AG) source works similar to as described above, however, the source client name provided in the Commvault configuration should be the MSSQL AG Client name as in the CommServe server.

General notes/troubleshooting

- Commvault backups are not on local storage and therefore while ingesting backups taken using Commvault, Backup Paths provided in configuration will be ignored.

## Linking a dSource from a netBackup SQL Server backup

### Customer requirements

- The version of NetBackup client on the staging environment must be the same as that on the source.
- The TCP port 8415 must be open from the staging host to the Delphix Engine
- Backups must be taken via an MS-SQL-Server type policy with an INSTANCE client list type. (value is 15, and 1 respectively) Only transaction logs, incrementals, and database full backups are currently supported.
- The master server and source client servers' clocks must be within a minute of each other (timezones can be different).
- Any backups that Delphix needs to ingest for a dSource must be taken to one NetBackup master server using one NetBackup SQL Server client. A multiple master server setup for one dSource is not supported.
- If the dSource is backed up with NetBackup, the source and staging environments must each have the NetBackup client installed.
- Both clients (on source and staging) during installation must be setup with the master server and the source and staging instances must be registered.
- The install path's bin directory of the SQL Server NetBackup client on the staging host must be part of the system PATH as we need access to dbbackex.exe and bplist.exe. This is typically located at
- If you have modified the PATH, then please restart the Delphix connector service otherwise the linking process won't be able to pick the changed system PATH environment variable.
- Configure redirected restores on the master server between the source NetBackup Client and the staging NetBackup Client
  - [https://www.veritas.com/support/en\\_US/doc/17221771-126559330-0/v113535700-126559330](https://www.veritas.com/support/en_US/doc/17221771-126559330-0/v113535700-126559330)

### Linking with netBackup backups

To link a dSource and use NetBackup, follow the steps to add the environments as before, and make sure all requirements listed above are met. Going through the linking wizard on the **Data Management** page, select **Show advanced**.

We use these names to query bplist using these options:

- When validating the master and client servers we expect that at least one NetBackup MS-SQL-Server type backup had been taken with this pair in the last two days. Validation will fail otherwise.

Using NetBackup config parameters or templates

When restoring we create a batch file based on information we find on the backup. Batch files can be customized with non-default and additional options using config templates.

[https://www.veritas.com/content/support/en\\_US/doc/123947690-126579517-0/id-SF930853806-126579517](https://www.veritas.com/content/support/en_US/doc/123947690-126579517-0/id-SF930853806-126579517) explains which parameters in the batch file can be edited outside of these blacklisted keywords:

- ALTCLIENT
- BROWSECLIENT
- DATABASE
- DUMPOPTION
- ENABLESERVICEBROKER
- ENDOPER
- MOVE
- NBIMAGE
- NBSERVER
- OBJECTNAME
- OBJECTTYPE
- RECOVERED STATE
- RESTOREBEFOREMARK
- RESTOREBEFOREMARK AFTERTIME
- RESTOREOPTION
- RESTOREPAGES
- PARTIAL
- PAGE Any key that is used outside of what is documented may cause the restore to fail with unknown errors.

If the **Configure NetBackup Config Template** is checked, the page after **Data Management** becomes **NetBackup Config Template**.

**Add dSource**

**Preparation**

**Source**

**dSource Configuration**

**Data Management**

**NetBackup Config Template**

**Policies**

**Hooks**

**Summary**

**NetBackup Config Template**

Select template

Default

Table Text

Name	Value
No Rows To Show	

Cancel Back Next Submit

This page allows this dSource's specific config parameters to be updated, either by adding rows to the table or inputting them as text input (key=value).

- For config params/templates, the 'value' will be injected into the script as is so if the value of the parameter needs to be a String, quotes should be included with 'value'.

If creating a new set of config parameters while linking each dSource seems unnecessary, a config template can be specified. However, that is only possible via the CLI. To do that, log onto the CLI using the Delphix admin user/ password and go to **database > templates**. Make sure to create the new template with sourceType set to MSSqlLinkedSource.

Example:

Then when linking, select the template created. (In this screenshot it would be **NetBackup**) If any edits are made to a selected template while linking, this will create a new set of config parameters for the specific dSource and will

not edit the actual template. Config parameters added to a specific dSource will be ignored if the dSource has a config template selected.

LogSync for SQL server dSources

LogSync can still be enabled if NetBackup ingestion is enabled however Point-in-Time provisioning is currently not supported for NetBackup transaction logs. LogSync for backups taken with other backup providers that support LogSync will work as before.

Enabling NetBackup for previously created dSources

On an already created dSource go to **Configure > Data Management** and click edit (pencil button). Enable NetBackup Ingestion and add all the configuration as necessary.

### Netbackup Ingestion ⓘ

Enabled

### NetBackup Config Template

Configure NetBackup Config Template

### Master Name

### Source Client Name

Validate

If **NetBackup Config Template** is set to **Default** then the params will be empty. Go to the CLI to update the config params.

```

Password:
ip-10-110-238-136> cd source
ip-10-110-238-136 source> select Biscuit
ip-10-110-238-136 source 'Biscuit'> update
ip-10-110-238-136 source 'Biscuit' update *> edit mssqlNetbackupConfig
ip-10-110-238-136 source 'Biscuit' update mssqlNetbackupConfig *> set configParams.BLOCK_SIZE=6
ip-10-110-238-136 source 'Biscuit' update mssqlNetbackupConfig *> ls
Properties
  type: MSSqlNetbackupConfig
  configParams:
    BLOCK_SIZE: 6 (*)
  configTemplate: (unset)
  masterName: nbu-80-master.delphix.com
  sourceClientName: ln-win2012src.dlpxdc.co
ip-10-110-238-136 source 'Biscuit' update mssqlNetbackupConfig *> commit

```

Like above, to create a config template, create the template first so that during this update that specific template can be selected in the drop-down.

Delphix Managed Backups must be disabled before NetBackup can be enabled. To disable Delphix Managed Backups for a specific dSource, select that specific dataset and go to **Data Management** tab under the **Configuration** tab.

Linking an availability group database with NetBackup

Linking with an AG source works similarly however the source client name inputted to the NetBackup config should be the windows cluster name rather than the client name that takes the backup.

General notes/troubleshooting

- If a restore fails and the staging environment’s NetBackup client job log shows no attempted restores, it is likely that you need to log onto the environment using the staging user provided to Delphix. This article

explains that the user profile is created on the first login and that NetBackup requires it to restore. [https://www.veritas.com/support/en\\_US/article.100032299](https://www.veritas.com/support/en_US/article.100032299)

- Through observation, we've noticed that the block size of the restore batch file must be equal to or less than what was used when backing up the dump. We default to the blocksize to what the backup was taken with but the config param/template can include BLOCK\_SIZE to change. We won't prevent this but it's up to the user to set it correctly. Editing this field is generally not recommended for this reason.
- NetBackup backups are not on local storage and therefore the Backup Paths will just be ignored.

## Restoring SQL backups stored in Azure cloud storage

### Need for supporting SQL backups stored in Azure cloud storage

Currently, you can restore the SQL backups that are stored locally on the staging host, or on the network path, or on the backup servers with third-party vendors such as Commvault or Netbackup. At the same time, there are users that are having their native SQL backups on Azure Cloud Storage.

Delphix now supports restoring native SQL backups from Azure Cloud Storage. This enables users who are moving to Azure to use direct backups from the Azure Storage containers instead of third-party vendors.

These backups support the following.

- This is supported by SQL Server 2016 and above
- All backup modes
  - Full backups
  - Differential
  - Transaction log backups Logsync (point-in-time provisioning) is currently not supported. However, LogSync can still be enabled if Azure backup is being ingested. LogSync for SQL native backups that are present on Disk will work as before.
- Striped backups All backup files are to be entirely present on the Azure Cloud and no part of a backup should be present outside of Azure Cloud.
- Validated Sync
- Azure Storage authentication mode This backup solution uses a shared access signature token authentication method to authorize access to the blob data.

### Workflow architecture

#### *Restoring SQL Backup from Azure Cloud Storage*

## Workflow Steps

- **User takes backup:** You need to take the SQL native backup directly to the Azure Cloud using SQL [Backup to URL](#). Performance can be improved by enabling COMPRESSION while taking the backup. If the backup size is large, it should be striped into multiple files.

```
BACKUP DATABASE [SourceDB4]
to URL = 'https://idea1201.blob.core.windows.net/ideal1201container/source.bak'
```

- **Authentication to authorize access to the blob data:**

You must create a [SQL Credential](#) on the staging host for the following cases.

- Create using SAS authentication token as Access Key authentication is currently not supported.
- Create for each Azure container where the backup files are expected to be stored.
- Create on each SQL instance where restore has to be performed.

```
CREATE CREDENTIAL [ https://idea1201.blob.core.windows.net/
ideal1201container] (this is the Azure Container URL)
WITH IDENTITY = 'SHARED ACCESS SIGNATURE',
SECRET =
'sv=2019-12-12&ss=bfqt&srt=c&sp=rwdlacupx&se=2021-01-19T14:18:04Z&st=2021-
01-19T06:18:04Z&spr=https&sig=DBLZnu0VQTaXUwY9IgBEqNbSk';
(provide the SAS token here)
```

- **Run queries on Staging host:** Delphix Engine uses this credential to run the following queries [Restore](#), [Restore Headeronly](#), and [Restore Filelistonly](#) on the staging host.
- Irrespective of whether auto-discovery is selected or not, if an Azure backup is being ingested, its location will be fetched from the `msdb.dbo.backupmediafamily` table on the source host and it will be restored on the staging host. Hence, it is necessary that the backup files are present on the same blob URL where the backup was originally taken. This is different from the usual native backups to the disk.

- In SQL native disk backup,
  - If auto-discovery is on, the backup path is fetched from `msdb.dbo.backupmediafamily` table on the source host.
  - If auto-discovery is off, Delphix Engine uses the custom path(s) specified by the user.
 If any native Azure backup is found, Delphix Engine will always try to restore it.
  - This is similar to the user taking backups using multiple backup vendors.
  - In that case, Delphix Engine tries to restore all backups, irrespective of the backup vendor.

## Unsupported features

The following features and functionalities are currently not supported.

- Third-party backup vendors
- Point-in-time provisioning
- Access key authentication method for Azure backups
- Support for SQL Server versions below SQL 2016
- Moving backup files across Azure containers
- Moving a backup from disk to cloud
- Striped backups - Backup files that are partially present on Azure Cloud and partially on another device.
- Managed identity

## Working with SQL Server snapshots

This section lists the steps to take a snapshot and delete the same.

Taking a snapshot creates a new snapshot entry in the Oracle dSource's Timeflow. You can use either **Snapshot (Default)** or **Snapshot with Parameters** option for taking the snapshot.

### Snapshot (Default)

Perform the following steps to take a snapshot:

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the **Camera** icon. Alternatively, click the arrow next to the Camera icon and select **Snapshot (default)**.
5. From the Snapshot dialog box, select **Yes**.
6. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the Snapshot you just created.
7. To delete the snapshot, select the snapshot you just created, and from the Actions menu (...), select **Delete Snapshot**.
8. From the **Delete Snapshot** dialog box, select **Delete**.
9. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just deleted.

### Snapshot with Parameters

Perform the following steps to take a snapshot:

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the arrow next to the Camera icon and select the **Snapshot with Params...** option.
5. From the Snapshot dialog box, select one of the following:
  - a. **Force Full Backup** - If you select this option, then the Delphix Engine will perform an incremental backup by default. You must select this option only when a full backup is required. Full and Incremental backups consume the same space on the Delphix Engine.
  - b. **Double Sync** - Selecting this option will perform a SnapSync operation as normal. After the first SnapSync is successful, the Engine will immediately perform a second SnapSync without waiting for the Log Files required for the first SnapSync to be made consistent. This is most useful when performing the initial SnapSync ( or when "Force Full Backup" is selected ) on a very large database that would lead to a large number of archive logs being required to make the SnapSync consistent. Provisioning from a SnapSync that requires excessive recovery is typically time-consuming.
  - c. **Do Not Resume** - If a failure is encountered during the initial SnapSync, the Delphix Engine can resume the SnapSync at a later date. This option will cause the engine to not resume, but rather to start the initial SnapSync over again.
6. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the Snapshot you just created.
7. To delete the snapshot, select the snapshot you just created, and from the Actions menu (...), select **Delete Snapshot**.
8. From the **Delete Snapshot** dialog box, select **Delete**.
9. Navigate to the **Timeflow** tab and click **View: All snapshots** to verify the snapshot you just deleted.

## Detaching and re-attaching SQL Server dSources

Each dSource contains metadata that associates it with the source database, as well as the data it has ingested from the source database in the form of snapshots up to that point. It is possible to detach, or unlink, a dSource from its source database. This breaks the association with the source database without affecting the data within the Delphix Engine. Detached dSources and their source databases have these properties:

- A detached dSources can still be used to provision a virtual database (VDB).
- You can re-link the source database as a different dSource.

### Prerequisites

A dSource can only be attached to a new data source once it has been unlinked.

### Detaching a dSource

1. Login to the **Delphix Management** application as a user with **OWNER** privileges on the dSource, group, or domain.
2. Click **Manage**.
3. Select **Databases**.
4. Select the **database** you want to unlink or delete.
5. From the **Actions** menu (...) select **Unlink**. A warning message will appear.
6. Click **Unlink** to confirm.

#### Rebuilding Source Databases and Using VDBs

In situations where you want to rebuild a source database but retain the existing dSource, you will need to detach the original dSource and create a new one from the rebuilt data source.

1. Detach the dSource as described in the procedure on this page.
2. You cannot attach a dSource with the same name as a dSource that is already attached. If you intend to give the new dSource the same name as the original one, rename the detached dSource.
  - a. At the top of the **Configuration** tab, next to the dSource's name, click the **Edit** (pencil) icon.
  - b. After renaming the dSource, click the green **checkmark**.
3. Create the new dSource from the rebuilt database.

You will now be able to provision VDBs from both the detached dSource and the newly created one, but the detached dSource will only represent the state of the source database prior to being detached.

### Attaching a previously detached dSource

You can only re-attach databases that represent the same physical database.

1. Login to the **Delphix Management** application as a user with **OWNER** privileges on the dSource, group, or domain.
2. Click **Manage**.
3. Select **Databases**.
4. Select the database you want to re-attach.
5. From the **Actions** menu (...) select **Link dSource**.
6. Select the environment and database that represents the source to which you would like to re-attach.
7. Select an appropriate staging environment, and choose the credentials that should be used to authenticate to the source database.
8. Click **Link** to link the dSource to the new source database.
9. Once linking is complete, use the **Configuration > Data Management** tab to set up an appropriate **Validated Sync** configuration.

### Attaching a previously detached dSource using CLI

You can only re-attach databases that represent the same physical database.

1. Login to the **Delphix CLI** as `delphix_admin` or a user with `OWNER` privileges on the dSource, group, or domain.
2. Select the dSource by name using `database select <dSource Name>`.
3. Run the `attachSource` command.
4. Set the source config you want to attach to, using `set source.config=<Source Database Unique Name>`. Source configs are named by their database unique name.
5. Set any other source configuration operations as you would for a normal link operation.
6. Run the `commit` command.

## Provisioning and managing virtual databases with SQL Server

Virtual databases are a key data management concept for Delphix. In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment. From a dSource, you can select a snapshot or point in time to create a VDB. SQL Server VDBs each have their own configuration settings.

This section covers the following topics:

- [Overview of SQL server virtual databases](#)
- [Provisioning a SQL server VDB](#)
- [V2P with a SQL server VDB](#)
- [Additional SQL server VDB topics](#)
- [CDC support in SQL server](#)
- [MSSQL V2P file mapping](#)

## Overview of SQL Server virtual databases

Virtual databases are a key data management concept for Delphix, explained in [Provisioning and Managing Virtual Databases](#). In order to create or provision a virtual database, you will need a linked dSource from a source host and a compatible target environment, as described in the overview for [Managing Environments and Hosts](#) and [Overview of Requirements for SQL Server](#).

From a dSource, you can select a snapshot or point in time to create a VDB. SQL Server VDBs each have their own configuration settings as described in Configuration Settings for SQL Server Virtual Databases below. This document describes the steps to provisioning VDBs with SQL Server.

### Procedure

1. In the Datasets panel on the left-hand side, click the group containing the dSource or VDB from which you want to provision and select the dSource or VDB from the provided list.
2. From the TimeFlow tab, select a snapshot to provision from. To provision from a specific point in time from dSources with LogSync enabled, use the open LogSync button.
3. Click to open the Provision VDB wizard, and select a compatible Target Environment for the new SQL Server VDB
4. On the Target Configuration page, you may customize the VDB. For a list of available configuration options, see [Configuration Settings for SQL Server Virtual Databases](#) below.
5. Select a Snapshot Policy for the VDB.
6. If the VDB should be masked during provisioning, enable Masked Provisioning by selecting an option on the Masking page
7. Enter any operations that should be run on the Hooks page.
8. Review the VDB Configuration and Summary, and then click Submit.

When provisioning starts, you can review the progress of the job by selecting the VDB and clicking on the Status tab, or by selecting System and viewing the Jobs page.

Alternatively, you can see this in the Actions Sidebar. When provisioning is complete, the VDB will be included in the group you designated and listed in the Datasets panel.

### Configuration settings for SQL server virtual databases

Each VDB has its own data management settings, found during the provisioning workflow as well as in the configuration page for that VDB. When you create a SQL ServerVDB, Delphix copies most configuration settings from the dSource and uses them to create the VDB. However, you can customize these with the following settings:

Setting	Explanation
Recovery Model	The current recovery model of the source database. By default, this value is set to SIMPLE. You must set it explicitly during provisioning.
Auto VDB Restart	Enabling this option will automatically restart this VDB whenever its target host is rebooted.
Change Data Capture (CDC)	Indicate whether this virtual source should be enabled for CDC.

### Configuration settings for SQL Server virtual databases

Database configuration settings for a SQL Server virtual database can be provided as a key-value pair. Currently, there is support for the below-mentioned configuration parameter(s). These parameter(s) can be added in a configuration template and then applied to virtual databases.

The following parameters are available for SQL Server VDBs:

VDB Configuration Parameters	Value	Explanation
READ_COMMITTED_SNAPSHOT	ON/OFF	Enables the READ_COMMITTED_SNAPSHOT isolation database option on the virtual database. By default, this option is set to OFF.

### VDB config templates

A VDB config template is a list of database configuration parameter names and values that you can save on the Delphix Engine to use at a later time.

### Creating a VDB config template via GUI

1. Log into the **Delphix Management** application as an engine administrator.
2. Click **Manage**.
3. Select **VDB Config Templates**.
4. Click the  icon next to the **VDB Config Temp...** and select **New Template** to create a new template.
5. In the **New Template** dialog window, enter the name for the new template, the parameters that you want to provide, and select the template type from the available options.

## New Template

✕

---

Name

Template Type

MSSQL Virtual Source
▾

Notes

Cancel

Create

6. Click **Create**.

Updating a VDB config template via GUI

1. Log into the **Delphix Management** application as an engine administrator.
2. Click **Manage**.
3. Select **VDB Config Templates**.
4. Select the template from the left-side pane that you need to update.
5. Click on the **pencil** icons next to the parameters to edit an existing VDB template.
6. To add a new parameter, click the **plus** icon, and enter a name and value of the parameter.

7. Click the  button to save the changes or click the  button to discard the changes that you made.

You can apply a VDB Config Template to a VDB during the provisioning process, which copies the values from the template. Any subsequent changes to the template will be reflected in the VDB when that VDB is refreshed/rewinded. During provisioning, you can specify configuration parameters directly or copy them from a VDB Configuration Template. Once set, the Delphix Engine will use these parameters whenever the VDB is refreshed/rewinded, even if you change the original template.

## Provisioning a SQL Server VDB

This topic describes how to provision a virtual database (VDB) from a SQL Server dSource.

### Prerequisites

- You must have already linked a dSource from a source database, as described in [Linking a SQL Server dSource](#) or have already created a VDB from which you want to provision another VDB.
- You must have already set up Windows target environments and installed the Delphix Connector on them, as described in [Adding a SQL Server Standalone Target Environment](#).
- Make sure that you have the required privileges on the target environment.
- If you are provisioning to a different target environment than the one where the staging database has been set up, make sure that the two environments have compatible operating systems. For more information on the staging database and the validated sync process.
- If using Change Data Capture (CDC):
  - The SQL Server instance on which the VDB is being provisioned or exported must support CDC.
  - The *SQL Server Agent* for the instance must be running otherwise adding a CDC capture and cleanup jobs will fail.

### Procedure

 When provisioning or refreshing a SQL Server VDBs, both the DB\_CHAINING and TRUSTWORTHY database parameters will be disabled (even if they were enabled on the dSource).

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select a **dSource**.
5. Click **Timeflow** tab.
6. Next to a snapshot select the  Provision VDB icon. The **Provision VDB** panel opens.
7. Select a **target environment**.
8. On the **Target Configuration** page, specify a **Mount Path**.
9. On the **Configuration** page, do the following:
  - a. Under **Target Group**, select a Target Group for the VDB.
  - b. Enter a database name.
  - c. Under Recovery Model, click the drop-down list to select a recovery model. You can choose one of the following:
    - i. Simple - This option is recommended and selected by default. It allows SQL Server to automatically mark parts of its transaction log file for re-use if they are not in use.
    - ii. Full - This option lets you take the responsibility for taking backups and log backups of the VDB to an external location.
    - iii. Bulk Logged - This option lets you take the responsibility for taking backups and log backups of the VDB to an external location.
  - d. Specify any **Pre Scripts** or **Post Scripts** that should be used during the provisioning process. For CDC users, it is recommended that VDB Post Start hooks be configured to automatically start these jobs on successful provisioning.
 

**Note** : It is advised to use a Post Start hook as it is executed in all VDB operations like provision, refresh, rewind, disable/enable. Also, CDC jobs get deleted whenever we disable a VDB. The Post Start hook will add the CDC jobs again on enabling the VDB.
  - e. Under VDB configuration, enable **Auto VDB Restart** to allow the Delphix Engine to automatically restart the VDB when it detects the target host reboot.
  - f. To enable **Change Data Capture (CDC)**, select the Enable checkbox.

- g. To enable VDB configuration parameters, select the **VDB Configuration Parameters** checkbox. This step displays a new page to either select an existing template or set configuration parameters. **Note** : READ\_COMMITTED\_SNAPSHOT is the only parameter that can be defined here, and the allowed values are OFF and ON. To do so, perform the following steps on the **VDB Configure Parameters** page:
  - i. Click the plus icon to add a new key-value pair as a new template for the configuration parameters.
  - ii. OR, From the **Select Template** dropdown list, select an existing configuration template to be applied on the VDB. Applied VDB Config Template will be displayed under the **Configuration** tab in the dataset and will remain editable.

- h. Click **Next**. **Note** : CDC documentation For more information see:
  - [About Change Data Capture](#)
  - [Enable and Disable Change Data Capture](#)
- 10. Under **Policies**, select a **Snapshot Policy** for the VDB and click **Next**.
- 11. Under **Masking**, select **Mask this VDB** checkbox to mask your data during provisioning and then select one of the following masking options:
  - a. Select an existing masking job
  - b. Masking Job is not currently available for the selected data type, please mask using script(s) instead. If you select this option, you should define a Configure Clone script in the Hooks step to mask the dataset.

12. Under **Hooks**, specify any Hooks to be used during the provisioning process. For more information, see [Hooks for SQL Server](#).
13. Click **Next**.
14. The final summary tab will enable you to review your configurations.
15. Click **Submit**.

When provisioning starts, the VDB will appear in the **Datasets** panel. Select the VDB and navigate to the **Status** tab to see the progress of the job. When provisioning is complete, you can see more information on the **Configuration** tab.

 You can select a SQL Server instance that has a higher version than the source database and the VDB will be automatically upgraded. For more information about compatibility between different versions of SQL Server, see [SQL Server Support Matrix](#).

### Provisioning by snapshot or logSync

When provisioning by snapshot, you can provision to the start of any particular snapshot, either by time or LSN.

 You can take a new snapshot of the dSource and provision from it by clicking the **Camera** icon.  
Provisioning By Snapshot

Provisioning By Snapshot	Description
Provision by Time	You can provision to the start of any snapshot by selecting that snapshot card from the <b>TimeFlow</b> tab, or by selecting and entering a value in the time entry fields. The values you enter will snap to the beginning of the nearest snapshot.
Provision by LSN	You can use <b>Provision by LSN</b> control to open the LSN entry field. Here, you can type or paste in the LSN to which you want to provision. After entering a value, it will "snap" to the start of the closest appropriate snapshot.

## V2P with a SQL Server VDB

This topic describes how to perform the Virtual to Physical (V2P) process with a SQL Server virtual database (VDB).

### Procedure

1. Log into the **Delphix Management** application.
2. Click **Manage** and select **Datasets**.
3. Select the dSource or VDB you want to export.
4. Select the snapshot of the dSource or VDB state you want to export.
5. If you want to export the state of the database from a specific point in time, select the **LogSync** icon and then select the point in time from which you want to create the export.

6. From the actions menu (...) select **Virtual to Physical**.
7. Select the target environment.
8. Enter the **Target Directory** for the export. The target environment should have been added to Delphix previously and should meet all target host requirements, see [Overview of Requirements for SQL Server Environments](#) for more information on user requirements for target environments. The target directory you enter here must exist in the target environment and the Delphix operating system user listed under the environment must have permission to write to it.
9. Select the checkbox to enable or disable the option **Open database after Recovery**. If you select to **disable** this option, you can use the scripts that are created in the target environment to manually recover the database at a later time. See [Manually Recovering a Database after V2P](#) for more information.
10. Click **Show Advanced** to customize the target directory layout or to enable Change Data Capture (CDC) on the exported database. See [Customizing Target Directory Structure for Database Export](#) for more information.
11. Click **Next**.
12. Select whether you want to have an email sent to you when the export process completes, and then click **Submit**.

### Post-requisites

If you have selected disable for **Open database after Recovery**, then follow the instructions in [Manually Recovering a Database after V2P](#) to complete the V2P process.

## Additional SQL Server VDB topics

This section covers the following topics:

- [Renaming a SQL Server VDB via CLI](#)
- [Upgrading SQL Server VDBs](#)
- [Extended properties for SQL Server VDBs](#)
- [File permissions for SQL Server VDBs](#)
- [Deleting a SQL Server VDB](#)

## Renaming a SQL Server VDB via CLI

This topic describes how to change the database name on the SQL Server Instance for VDB through the Delphix CLI.

**i** Database name on SQL Server vs. VDB name on Delphix  
 The database name is what you would see the SQL Server instance on the Target in SQL Server Management Studio or sys.databases. It is also the database name in the **Configuration** tab in Delphix. The name of the VDB is an internal name within Delphix Engine and does not need to be the same as the database name on Target. This is found on the **Status** tab of Delphix.

### Prerequisites

- The VDB must be running on the target environment.
- The SQL Server instance on the target environment where the VDB is located must be up and reachable.

### Procedure

1. Select the **source** associated with the VDB and disable the VDB.

```
delphix> source "vexample"
delphix source 'vexample'> disable
delphix source 'vexample' disable *> commit
```

2. Select the source **config** associated with the source.

```
delphix source "vexample" > get config
vexample
delphix source "vexample" > /sourceconfig "vexample"
delphix sourceconfig "vexample" >
```

3. Update the **databaseName** to the new name.

```
delphix sourceconfig "vexample" > update
delphix sourceconfig "vexample" update *> set databaseName=newDBName
delphix sourceconfig "vexample" update *> commit
delphix sourceconfig "vexample" >cd
```

4. Enable the VDB.

```
delphix> source "vexample"
delphix source 'vexample'> enable
delphix source 'vexample' enable *> commit
```

## Upgrading SQL Server VDBs

This topic describes how to upgrade a SQL Server VDB to a higher version of SQL Server instance.

### Procedure for VDB in-place upgrade

1. Remove any VDB Refresh Policy assigned to the VDB.
2. Upgrade the target SQL Server instance.
3. Refresh the target environment.

### Procedure to upgrade a VDB to a new SQL instance

1. Refresh all environments.
2. Login to the **Delphix Management** application.
3. Click **Manage**.
4. Select **Datasets**.
5. Select the **VDB** to be upgraded.
6. From the **Actions** menu (...) select **Disable**.
7. Click **Disable** to confirm.
8. From the **Actions** menu (...) select **upgrade**. The **Upgrade Database** window will open.
9. Select the **SQL Server instance** to which you want the VDB to upgrade.
10. Click **OK**.
11. Enable the VDB. (See the *Enabling and Disabling SQL Server VDBs* section in [Provisioning and Managing Virtual Databases](#).)
12. Repeat steps 5 to 12 for each VDB you want to upgrade.

## Extended properties for SQL Server VDBs

### Extended properties and how to view them

This topic describes extended properties on VDBs that you can use to track the origin of VDBs through SQL Server tools on target servers.

These are the extended properties:

Property	Description
<code>dlpx_server_name</code>	Address of the Delphix Engine hosting the VDB
<code>dlpx_server_uuid</code>	UUID of the Delphix Engine hosting the VDB
<code>dlpx_source_id</code>	Internal reference of the VDB

You can find these properties in the following locations:

- For a VDB using the SQL Server Management Studio tool: under the Extended Properties page of the Properties window
- Using the `sp_dlpx_vdbinfo` stored procedure.
  - To install and run this stored procedure, run the SQL code contained in `<Delphix Connector install path>\etc\sp_dlpx_vdbinfo.sql`.

### File permissions for SQL Server VDBs

When provisioning a VDB, the Delphix Engine modifies the "access control lists" (ACLs) of database and log files to help prevent unintentional data loss through file deletion. Files could be deleted, for example, if there is an attempt to DROP a VDB directly through SQL Server management studio or other native SQL Server tools.

The Delphix Engine updates each database and log file ACL to include a deny-delete "access control entry" (ACE) for the user account running the SQL Server instance.

You can still drop VDBs directly through SQL Server tools. However, a warning message will be displayed, and the files will remain on the volume that the Delphix Engine exports. This file deletion prevention also applies to attempts to remove files from a database using the ALTER DATABASE .. REMOVE FILE command.

If a VDB is inadvertently dropped, you can reattach the database using SQL Server tools.

If you attempt to delete a database or log file and then try to add a file of the same name, this may fail because the original file was prevented from being deleted by the deny-delete ACE.

If you intend to delete the files from the volume that the Delphix Engine provides, you can change the ACLs on the files using the `icacls` command:

```
icacls <file> /remove <SQL Server instance account>:deny(D)
```

Accounts other than the SQL Server instance account will not be prevented from deleting the VDB database and log files.

## Deleting a SQL Server VDB

### Procedure

 Deleting a VDB is an unrecoverable operation. Proceed only if you want to permanently destroy the unique data that was created in the VDB.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **VDB** that you want to delete.
5. From the Actions menu (...) select **Delete**.
6. If stopping or starting the VDB requires particular credentials for the target environment other than those of the default environment user:
  - a. Check **Provide Privileged Credentials**.
  - b. Enter the **username** and **password**.
  - c. Click **Validate Credentials**.
7. Click **Delete** to confirm that you want to delete the VDB.

If the VDB was currently active, the Delphix Engine will shut it down, unmount all filesystems from the target environment, and finally delete the VDB itself.

### Using force delete

Deleting unused or outdated objects should be a regular part of Delphix Engine administration. This is especially important to prevent low space errors, which can cause the Delphix Engine to stop. The Delphix Engine holds a maximum of 400 objects.

1. Log into the **Delphix Management** application.
2. Select **Resources > Storage Capacity**.
3. Next to the object you want to delete select the **Trashcan**.
4. In the Delete dialog select **Force Delete**. Oracle users will have the option to provide additional credentials.

### Delete Dataset Child VDB ✕

Are you sure you want to delete dataset "Child VDB"?

Force Delete

Provide privileged credentials

Cancel Delete

5. Click Delete.

#### Dependencies

If there are dependencies on the snapshot, you will not be able to delete the snapshot free space; the dependencies rely on the data associated with the snapshot. These items are displayed with a lock icon next to the name.

## Delete Dataset dbdhcp1

### Unable to delete dataset dbdhcp1

**Dataset dbdhcp1 is locked due to the following dependencies:**

VDB "C3" has been provisioned from it

VDB "C1" has been provisioned from it

**Dataset C3 is locked due to the following dependencies:**

VDB "C4" has been provisioned from it

VDB "C6" has been provisioned from it

Self Service template "JSDataTemplate(C3)" has a reference to it

**Dataset C4 is locked due to the following dependencies:**

VDB "C5" has been provisioned from it

Self Service container "JSContainer(C4)" has a reference to it

**Dataset C1 is locked due to the following dependencies:**

VDB "C2" has been provisioned from it

Copy to Clipboard

Close

Deleting a VDB associated with a self-service container

As shown below if a VDB is associated with a Self-Service container, the delete option will not show.

The screenshot displays the 'Vrh7\_2TM' dataset in the 'Timeflow' view. The interface includes tabs for 'Timeflow', 'Status', and 'Configuration'. A dropdown menu is open over the 'Timeflow' view, showing options: 'Undo Refresh or Rewind', 'Disable', 'Upgrade', 'Migrate', and 'Delete'. The 'Timeflow' view shows a list of snapshots for 'AUG 2, 2019' (3 Snapshots total). The snapshots are:

- 2:09 PM Refresh (Refresh Point)
- 2:07 PM Snapshot
- 2:02 PM Snapshot (Starting Point)

The right-hand panel shows 'Dataset Details' with the following information:

- STORAGE USED**
- Snapshots**
- Dataset Storage**: 205.00KB
- Total Engine Storage**: 21.80GB
- LOCATION & LINEAGE**
- Environment**: Oracle-Target
- Parent**: rh74db02
- Self-Service Containers**: Test01-C

A red arrow points from the 'Starting Point' label in the snapshots list to the 'Self-Service Containers' section in the metadata panel.

Users will need to first delete the container and then delete the VDB. Refer to [Delphix Self-Service Data Container Activities](#).

## CDC support in SQL Server

Provisioning CDC enabled virtual databases

Please see [Provisioning a SQL Server VDB](#).

Viewing or updating CDC your configuration

CDC configuration used while provisioning would be saved and used for subsequent Refresh and Rewind operations on the VDB. This configuration can be viewed/updated after the VDB has provisioned, in the ‘Source’ tab under the **Configuration**’section of the VDB.

Exporting CDC enabled physical databases

1. In the Configuration page of the wizard, open the Advanced section and Select the ‘**Enable**’ option under ‘Change Data Capture (CDC)’

## Virtual to Physical

Simple

Open Database After Recovery

Hide advanced

**Data Directory**  
data

**Archive Directory**  
archive

**Temp Directory**  
temp

**External Directory**  
external

**Script Directory**  
script

**Change Data Capture (CDC)** ⓘ  
 Enable

2. CDC capture and cleanup jobs have to be added and CDC metadata has to be upgraded (if exporting is done from a lower database version to SQL2016 and above), manually on exported databases.

## General notes/troubleshooting

- Make sure the SQL Server instance on which the VDB is being provisioned or exported, supports CDC.
- Make sure 'SQL Server Agent' for the instance is running otherwise adding CDC capture and cleanup jobs will fail.

## MSSQL V2P file mapping

### Introduction

This article describes how to customize file path mappings when performing a Virtual to Physical (V2P) operation for MSSQL databases. During the V2P process, it could be required to create mappings between the files and directories existing on the staging host, as well as files and directories created on the target. For example, putting all of the transaction log files that exist on the staging environment into a folder on the target machine.

The **Configuration** section of the process has name fields that can be specified for the database and directories, as shown in the screenshot below.

- Database Name: V2PDatabase
- Target Directory: C:\temp
- Data Directory: data
- Archive Directory: archive
- Script Directory: script
- Temp Directory: temp
- External Directory: external

### Virtual to Physical

**Configuration**

Ensure that the Database Name and Target Directory are defined appropriately for the physical database that will be created, and select the desired Recovery Model.

**Database Name**

**Target Directory**

Target Directory path is combined with other directories such as Data Directory, Archive Directory, Temp Directory, etc to build the full path for data files, archive logs, temp files, etc.

**Recovery Model**

Open Database After Recovery

Hide advanced

**File Mapping**  
 Configure File Mapping

**Data Directory**

**Archive Directory**

**Temp Directory**

**External Directory**

**Script Directory**

**Change Data Capture (CDC) <sup>®</sup>**  
 Enable

When working with File Mappings, the data file names affect everything that follows. These data files, including log files and File Streams folders, inherit file names from the dSources and VDBs by default (e.g., SourceDB2.mdf, SourceDB2\_log.ldf, File\_Stream, etc.). Users have control over the data files that are part of the dSource and VDB snapshots.

Archive log files go directly into the **C:\temp\archive** directory. If provided, the V2P process automatically appends the target directory and data directory to the data file names, as shown in an example list below.

- C:\temp\data\SourceDB2.mdf
- C:\temp\data\SourceDB2\_log.ldf
- C:\temp\data\File\_Stream

### Pattern matching

Pattern Matching rules can be used to create full path names for data files and control files. These rules have take this format: **source-regex-expression-KEY ? target-replacement-VALUE**. Multiple rules can be used and are applied successively. In addition, multiple rules with the same source key are allowed.

### File mapping options

#### Example 1

For this example, the ultimate goal is to perform a V2P operation that has the following data file File Mappings:

- C:\temp\SourceDB2\data\SourceDB2.mdf
- D:\temp\SourceDB2\logFiles\SourceDB2\_log.ldf
- E:\temp\SourceDB2\fileStream\SourceDB2\_File\_Stream

The default behavior can be changed to modify the target directory, modify the data directory, or modify the individual file location

- Modify the target directory.
- Modify the data directory.
- Modify the individual file location by using File Mapping.

To modify the location of each file, select **Configure File Mapping** in the **Advanced** tab of the Configuration page.

#### Virtual to Physical

Click the + button to add a new File Mapping or fetch all of the available data files that can be modified by simply clicking **Validate** with an **empty** File Mapping list, as shown in the screenshot below.

Virtual to Physical

The screenshot shows the 'File Mapping' configuration page. On the left, a vertical navigation menu includes 'Target Environment', 'Configuration', 'File Mapping' (highlighted with a blue dot), and 'Summary'. The main content area is titled 'File Mapping' and features a search bar with 'Find' and 'Replace' labels. Below the search bar is a table with three columns: 'Current', 'New', and 'Copy to Mapping Rules'. The table contains the following entries:

Current	New	Copy to Mapping Rules
SourceDB2.mdf	C:\temp\SourceDB2\data\SourceDB2.mdf	<input type="checkbox"/>
SourceDB2_log.ldf	C:\temp\SourceDB2\data\SourceDB2_log.ldf	<input type="checkbox"/>
File_Stream	C:\temp\SourceDB2\data\File_Stream	<input type="checkbox"/>

A 'Validate' button is located at the bottom right of the table area.

When modifying the file location for the received files, the **Copy to Mapping Rules** option copies the current (source location) and new (target location) to File Mapping, or the values can be entered manually to Find and Replace. The steps below are to follow.

1. Since the new (target location) of the SourceDB2.mdf would appended to **C :**  
**\temp\SourceDB2\data\SourceDB2.mdf** (a combination of **C:\temp\SourceDB2** (target directory), **data** (data directory), and **SourceDB2.mdf** (file name)), applying File Mapping is not necessary.
2. Copy the SourceDB2\_log.ldf file using the **Copy to Mapping Rules** option.
3. Place the SourceDB2\_log.ldf file into the **D : \temp\SourceDB2\logFiles\SourceDB2\_log.ldf** location.
4. Configure **Replace** to **D : \temp\SourceDB2\logFiles\SourceDB2\_log.ldf** and then select **Validate** to see the results.

Virtual to Physical

This screenshot shows the 'File Mapping' configuration page after the second step. The 'Find' field is empty, and the 'Replace' field now contains the path **D:\temp\SourceDB2\logFiles\SourceDB2\_log.ldf**. The table below shows the updated mapping:

Current	New	Copy to Mapping Rules
SourceDB2.mdf	C:\temp\SourceDB2\data\SourceDB2.mdf	<input type="checkbox"/>
SourceDB2_log.ldf	D:\temp\SourceDB2\logFiles\SourceDB2_log.ldf	<input type="checkbox"/>
File_Stream	C:\temp\SourceDB2\data\File_Stream	<input type="checkbox"/>

The 'Validate' button remains at the bottom right.

5. Similarly, to move **File\_Stream** to **E : \temp\SourceDB2\fileStream\SourceDB2\_File\_Stream**, provide the mapping as shown below.

Virtual to Physical

6. Select **Validate** between each new entry, in order to verify that data files are being mapped as expected.
7. The File Mappings build upon one another, so all the provided File Mapping Rules are applied sequentially to each source file in order to generate a target file location.
8. Once all the files are located as desired, select **Next** to continue the provision process.
9. The **Summary** page will show the modifications to **Target Directory** and **Database Name** directories, and will show that **Customized File Mapping** was defined.
10. After V2P completes, login to the target server and verify that the data files were mapped correctly.

Example 2

In this example, several rules are applied to the source file path for **SourceDB2.mdf**. Note that the rules are applied in sequential order, as shown in the screenshot below.

1. Applying the rule **Source?McLaren** results in: **C:\temp\data\McLarenDB2.mdf**
2. Applying the rule **McLaren?Ferrari** results in: **C:\temp\data\FerrariDB2.mdf**
3. Applying the rule **FerrariDB2?FerraiNew** results in: **C:\temp\data\FerraiNew.mdf**
4. Applying the rule **Source?no** results in an error, because **Source** is no longer found in the pathname.

## Virtual to Physical

- Target Environment
- Configuration
- File Mapping**
- Summary

### File Mapping

+

Find	Replace
Source	McLaren
McLaren	Ferrari
Source	No
FerrariDB2	FerrariNew

File mappings [Find="Source", Replace="No"] does not match any of the source paths.  
Provide different mapping rules.

During the pattern matching process, various errors can be generated. Some of these errors are described below.

1. **No match for specified mapping rules** When none of the rules match a source file
2. **Invalid regex pattern specified for path mapping** An invalid regex rule mapping error
3. **File Extension Mismatch** A modified file extension or folder to file conversion error
4. **Duplicate target Paths** When the same target path is created for multiple source files

The [java.regex.util class article](#) (redirect to [docs.oracle.com](https://docs.oracle.com)) shows the regular expression syntax and constructs recognized by the Delphix Engine pattern-matching operations.

## Hooks for SQL Server

### Overview

This topic describes the use of hook operations with dSources created from SQL Server source databases and virtual databases (VDBs) that are created from SQL Server dSources or other VDBs.

**Hooks** are Windows Powershell code executed on:

1. The staging target host before or after the manual snapshot of a dSource.
2. The VDB target host before and after the provision, refresh, rewind, snapshot, start or stop of a VDB.

#### Powershell version

While creating a hook, a user can provide the PowerShell version (default version or version 2) in the field "Operation Type" and this PowerShell version will be used to execute the hook script. Here, the default version is the version of PowerShell installed on the target host.

Hooks can be specified in the wizard used during the creation of a VDB, or modified afterward by navigating to the Configuration > Hooks tab. Hooks can also be set using the Delphix command-line interface (CLI) or REST Web API.

Each hook operation represents a user-configurable action that the Delphix virtualization engine will execute. You can configure the custom hook code to fail if they encounter an unexpected error. The failure of a hook operation will cause the enclosing operation to fail.

The Windows environment user for the dSource or VDB runs the "Powershell" executable, which runs the specified PowerShell script on the Staging or VDB Target host. The Delphix Engine captures and logs all output of the script and displays it if a failure occurs.

The intent of hook operations are customization of the data contents or configuration of a dataset while it is being manipulated. Actions performed by hooks effectively become an integrated part of the sync operations of a dSource or the provision, refresh, rewind, snapshot, start, or stop actions for that VDB.

Hooks are mainly used for pre- and post-provisioning operations. For example, you can use hooks to:

- Back up test data before refresh and rewind
- Back up data after provisioning
- Reset configuration settings from production to non-production settings after provisioning
- Create logins for dev/qa users who do not have privileges on production databases
- Sync logins on the target that are cloned from the production database
- Back up configuration data from the database

For more information on Hook Operations, see [SQL server hook operation notes](#)

## Hook operation templates

You can use operation templates to store commonly used operations, which allows you to avoid repeated code entry when an operation is applicable to more than a single hook, dSource, or virtual dataset. You can manage templates through the Delphix Management application.

You can also create templates from existing hooks by exporting the hooks in the Delphix Management application.

While creating a hook template, the user can provide the PowerShell version (default version or version 2) in the field "Type" and this PowerShell version will be used to execute the hook's script created from this template. Here, the default version is the version of PowerShell installed on the target host.

## New Template ✕

---

**Name**

**Type**

System Shell Command

Bash Shell Command

Expect Script

PowerShell Script (with default version)

PowerShell Script (with version 2)

**Description**

**Content**

---

Cancel
Create

The existing template's PowerShell version can be changed by using Delphix CLI only because UI currently does not support this feature.

### Windows environment variables

When a hook is executed, Delphix will set specific Windows environment variables to provide context, such as the name of the current host, the name of the SQL Server instance and port, and the name of the database. For more information, see [SQL server hook operation notes](#)

## Python script to migrate hooks from PowerShell version 2 to host's default PowerShell version.

### Overview

With 6.0.3.0, the Delphix Engine will use the default PowerShell version installed on the host (hereinafter referred as default PowerShell) to perform all its operations, also the new hooks and hook templates can be created using the default PowerShell. The existing hooks and hook templates on the engine will continue functioning using PowerShell version 2, and there will be an option to migrate them to use default PowerShell.

The article intends to introduce a Python script that can be used to migrate all the hooks and hook templates on the engine to default PowerShell. The motivation behind writing the script is to save the manual effort required in doing the migration via the UI or CLI.

[Link to download the script.](#)

### Requirements for running the script

The requirements for running the script are as follows, they are the same as running any Python script in general.

1. The machine where the script is run should have Python installed.
  - a. Relevant link: <https://www.python.org/downloads/>
  - b. The script is supported for both Python 2 and Python 3 release.
2. The machine where the script is run should have the 'delphixpy' Python package installed.
  - a. Relevant link: <https://pypi.org/project/delphixpy/>
  - b. [python.org](#) documentation on installing packages and creating Python environments: [Installing packages using pip and virtual environments.](#)
  - c. If the package is already installed, it should be upgraded to the latest version, the minimum *delphixpy* version required to run the script is 1.11.3.0
3. The Delphix Engine should be accessible from the machine where the script is run since the script makes API requests to the Delphix Engine to perform the migration,
  - a. The easiest way to verify the same is to use the **ping** command.

### Functionalities of the script

1. The script can migrate the hooks and hook templates in the Delphix Engine to run with default PowerShell.
2. The script can also migrate the hooks and hook templates back to PowerShell version 2.
3. It is possible to migrate only the hooks or only the hook templates.
4. If **INSTALLEDPOWERSHELL** feature flag is enabled on the Delphix Engine, the script will disable the same.

### The script parameters and usage

Script parameter	Description	Type	Possible values	Default value
--help	Displays the description and usage details of the parameters for the script on the terminal	Optional	Not applicable	Not applicable
--engine-addr	The Delphix Engine host address.	Required	Not applicable	Not applicable

Script parameter	Description	Type	Possible values	Default value
--sys-admin-usr	The username for System Administrator user to log into the Delphix Engine.	Required	Not applicable	Not applicable
--sys-admin-pwd	The password for System Administrator user to log into the Delphix Engine.	Required	Not applicable	Not applicable
--admin-usr	The username for Delphix Administrator user to log into the Delphix Engine.	Required	Not applicable	Not applicable
--admin-pwd	The password for Delphix Administrator user to log into the Delphix Engine.	Required	Not applicable	Not applicable
--hook-ps-version	Migrates all the hooks to PowerShell Version two.	Optional	default, ps2	default
--hook-templ-ps-version	Migrates all the hook templates to PowerShell Version two.	Optional	default, ps2	default
--migrate-only	Migrates only the hook or only the hook templates.  Input "hooks" for migrating only the hooks, whereas input "templates" for migrating only the hook templates	Optional	hooks, templates, hooks-and-templates	hooks-and-templates
--debug	In case there is an error executing the script, prints the Python stack trace required for debugging.	Optional	Not applicable	Not applicable

#### Command examples

1. Displaying the description and usage details of the parameters for the script on the terminal

```
python <path to the script> --help
```

2. An example command for migrating all the hook and hook templates to default PowerShell version:

```
python <path to the script> --engine-addr engine.delphix.com --sys-admin-usr
sysadmin --sys-admin-pwd sysadmin --admin-usr admin --admin-pwd delphix
```

3. An example command for migrating all the hook and hook templates to PowerShell version 2:

```
python <path to the script> --engine-addr engine.delphix.com --sys-admin-usr
sysadmin --sys-admin-pwd sysadmin --admin-usr admin --admin-pwd delphix --hook-
ps-version ps2 --hook-templ-ps-version ps2
```

Please note that this will migrate all the hooks and hook templates in the Delphix Engine to PowerShell version two, the script does not have the functionality to perform the migration for specific hooks or hook templates.

4. An example command for migrating only the hook templates:

```
python <path to the script> --engine-addr engine.delphix.com --sys-admin-usr
sysadmin --sys-admin-pwd sysadmin --admin-usr admin --admin-pwd delphix --
migrate-only templates
```

5. An example command for running the script in debug mode:

```
python <path to the script> --engine-addr engine.delphix.com --sys-admin-usr
sysadmin --sys-admin-pwd sysadmin --admin-usr admin --admin-pwd delphix --debug
```

#### Common errors while running the script:

1. If the Delphix engine is not accessible from the machine where the script is run, the connectivity test run by the script prior to running the migration will fail, and the following error will be thrown:

```
Error occurred while connecting to the engine via the given Delphix System
Administrator user:
[Errno 8] nodename nor servname provided, or not known
```

```
Error occurred while connecting to the engine via the given Delphix
Administrator user:
[Errno 8] nodename nor servname provided, or not known
```

The connectivity test run by the script prior to running the migration will fail if the value of the required parameters provided is not correct, and the following error will be thrown:

```
Error occurred while connecting to the engine via the given Delphix
Administrator user:
HTTP status was 401 when doing POST '{"username": "admin", "password": "blah",
"type": "LoginRequest", "target": "DOMAIN"}' to '/resources/json/delphix/login':
{"type":"ErrorResult","status":"ERROR","error":{"type":"APIError","details":{"I
nvalid username or password.,"action":"Try with a different set of
credentials.,"id":"exception.webservices.login.failed","commandOutput":null,
"diagnoses":[]}}
```

- 
2. If for some reason, the script execution stops in between before migrating all the hooks and hook templates, it's perfectly fine to run the script again; each time the script is run, the hooks and hook templates will be migrated to the specified PowerShell version.

## SQL Server hook operation notes

### SQL Server clusters

When linking from, or provisioning to cluster environments, hook operations will not run once on each node in the cluster. Instead, the Delphix Engine always runs all hooks on the instance primary node.

### Run PowerShell operation

The Run PowerShell operation executes a PowerShell script on a Windows environment. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output of the script. If the script fails, the output is displayed in the Delphix Management application and command-line interface (CLI) to aid in debugging.

If successful, the script must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

### Example of a run PowerShell Operation

You can input the full command contents into the Run PowerShell operation.

```
$removedir = $Env:DIRECTORY_TO_REMOVE

if ((Test-Path $removedir) -And (Get-Item $removedir) -is [System.IO.DirectoryInfo])
{
    Remove-Item -Recurse -Force $removedir
} else {
    exit 1
}
exit 0
```

### SQL server environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set environment variables so that the user-provided operations can use them to access the dSource or VDB.

### dSource environment variables

Environment Variables	Description
<code>SOURCE_INSTANCE_HOST</code>	The hostname of linked instance for the dSource
<code>SOURCE_INSTANCE_PORT</code>	Port of linked instance for the dSource
<code>SOURCE_INSTANCE_NAME</code>	Name of linked instance for the dSource
<code>SOURCE_DATABASE_NAME</code>	Name of database linked for the dSource

## Staging variables

We have the following environment variables applicable to Staging Push dSources.

Environment Variables	Description
STAGING_INSTANCE_HOST	The hostname of the staging instance
STAGING_INSTANCE_PORT	Port number of the staging instance
STAGING_INSTANCE_NAME	Name of the staging instance
STAGING_DATABASE_NAME	Name of the staging database
STAGING_MOUNT_BASE	Mount path for the staging push dSource
STAGING_DATA_DB_FILE_PATH	Filepath of the staging database

## VDB environment variables

Environment Variables	Description
VDB_INSTANCE_HOST	The hostname of linked instance for the VDB
VDB_INSTANCE_PORT	Port of linked instance for the VDB
VDB_INSTANCE_NAME	Name of linked instance for the VDB
VDB_DATABASE_NAME	Name of database linked for the VDB

## Error handling for SQL server PowerShell scripts

If a pre-script or post-script encounters an unrecoverable error during execution, the Delphix Engine expects the script to return with a non-zero exit code or the error will not be detected. The **Powershell -File** prefix and **exit \$LASTEXITCODE** suffix are required to pass the script's exit code up to the layer calling the script.

- Delphix does not perform error checking on PowerShell hook scripts. The script should perform error checking and logging, and return a non-zero exit code to indicate the script's failure. Failure to return a non-zero exit code when appropriate means that Delphix will think the hook script succeeded and mark

the VDB provision/refresh/rewind job as a success, when it should be seen as a failure. This is especially important when masking data is part of the hook – the VDB should not be released to users when the hook failed to mask data.

PowerShell gives you a few ways to handle errors in your scripts:

- Set `$ ErrorActionPreference` . This only applies to PowerShell Cmdlets. For scripts or other executables such as `sqlcmd` , PowerShell will return with exit code 0 even if there is an error, regardless of the value of `$ErrorActionPreference` . The allowable values for `$ErrorActionPreference` are :
  - `Continue` (default) – Continue even if there is an error
  - `SilentlyContinue` – Acts like Continue with the exception that errors are not displayed
  - `Inquire` – Prompts the user in case of error
  - `Stop` : Stops execution after the first error
- Use exception handling by using traps and try/catch blocks to detect errors and return with non-zero exit codes
- Use custom error handling that can be invoked after launching each command in the script to correctly detect errors. The following example shows how you can use the function `verifySuccess` to detect whether the previous command failed, and if it did print, print an error message and return with an exit code of **1**.

```
function die {
    Write-Error "Error: $($args[0])"
    exit 1
}
function verifySuccess {
    if (!$?) {
        die "$($args[0])"
    }
}
Write-Output "I'd rather be in Hawaii"
verifySuccess "WRITE_OUTPUT_FAILED"
& C:\Program Files\Delphix\scripts\myscript.ps1
verifySuccess "MY_SCRIPT_FAILED"
```

## Using pre- and post-scripts with SQL Server dSources

### Overview

This topic describes the use of pre- and post-scripts with dSources that are created from SQL Server source databases.

Pre-scripts and post-scripts are Windows PowerShell code executed on the Staging Target host before and after a SnapSync of a dSource. You can specify pre- and post-scripts in the wizard for creating a dSource, or you can modify them afterward by navigating to the Configuration > Standard tab. You can also set pre- and post-scripts using the Delphix command-line interface (CLI) or REST Web API.

The Delphix Engine executes a pre-script on the Staging Target host prior to the SnapSync of a dSource. If it is an initial snapshot, or manual snapshot by selecting the snapshot button on the GUI, the pre/post scripts do not get executed for dSources. Since the dSource resides within a restoring database in the SQL instance on the Staging Target host, the script can perform queries on the instance if a database account is available.

Hooks do allow for a pre/post snapshot hook, but the pre/post scripts do not

A post-script is executed after the SnapSync on a dSource completes. If the post-script fails, the provision, refresh, or rewind operation will also fail with an error message, and a fault will be created on the dSource.

 Pre/Post hooks allow for pre/post snapshot hooks for which there is no equivalent in the old pre/post scripts. Pre/Post scripts are run during validated sync, for which there is no equivalent hook operation today. Pre- and post-scripts are supported for backward compatibility with older versions of the Delphix Engine.

### Associating scripts with a dSource

Pre- and Post-scripts can be associated with a dSource in one of two ways:

#### During the dSource linking process

1. Login to the **Delphix Management** application.
2. In the top menu bar, click **Manage**.
3. Select **Datasets**.
4. Select the **Plus** icon and then select **Add dSource**.
5. In the **Hooks** tab of the **Add dSource** wizard, select the Plus icon to add new **Pre Script** and **PostScript** hooks.
6. Enter the calling syntax of the Windows PowerShell script into either or both of the appropriate fields.
  - a. The calling environment is used during linking, as shown in the **Environment Details** panel of the Delphix environment (**Manage > Environments**)
  - b. Four (4) environment variables will be populated with the name of the Delphix dSource, the SQL Server instance name and port, and the SQL Server database
  - c. name.

#### After linking, using the configuration tab of the datasets details page

1. Login to the **Delphix Management** application.
2. In the top menu bar, click **Manage**.
3. Select **Datasets** to display the SQL Server dSources and VDBs.
4. Select a SQL Server **dSource** from the listed **Datasets** in the left-hand navigation bar.
5. Click the **Configuration** panel, select the Hooks sub-tab.
6. By selecting a Plus icon you can create hooks from a template or create a new hook.

 **VDel\_JLP** 

---

Timeflow                      Status                      Configuration

---

Source                      Policies                      Data Management                      Masking                      Hooks

No operations
- ▼ **Post Refresh**  
No operations
- ▼ **Pre Rollback**  
No operations

**Configure Clone**

**DESCRIPTION**  
Operations performed on initial provision and after a refresh.

**OPERATION ORDERING**

---

No operations for this hook point.

7. Enter the calling syntax of the Windows Powershell script into either or both of the appropriate fields
  - a. The calling environment is that of the **primary Environment User account**, as shown in the **Environment Details** panel of the Delphix environment (**Manage > Environments**)
  - b. Four (4) environment variables will be populated with the name of the VDB, the SQL Server instance name and port, and the SQL Server database name.
  - c. Select the **Create** to accept the change.

Execution context for SQL server scripts

For dSources, pre- and post-scripts are executed in the context of the staging host user that was provided when linking.

## Using pre- and post-scripts with SQL Server VDBs

### Overview

This topic describes the use of pre- and post-scripts with virtual databases (VDBs) that are created from SQL Server dSources.

Pre-scripts and post-scripts are Windows PowerShell code executed on the VDB target host before and after the provision, refresh, or rewind of a VDB. You can specify pre- and post-scripts in the wizard for creating a VDB, or you can modify them afterward by navigating to the Configuration > Standard tab. You can also set pre- and post-scripts using the Delphix command-line interface (CLI) or REST Web API.

The intent of these scripts is a customization of the data contents or configuration of a VDB while it is being manipulated. Actions performed by pre-scripts and post-scripts effectively become an integrated part of the provision, refresh, or rewind actions for that VDB.

The pre-script executes during the initial provision of a VDB. During refresh and rewind, the PowerShell script referenced in a pre-script is executed after the VDB has been stopped and unmounted, but before the new VDB is mounted. If the pre-script fails, the refresh or rewind operation will also fail with an error message.

During provision, refresh, and rewind, the PowerShell script referenced in a post-script is executed after the Delphix engine has mounted and started the VDB. If the post-script fails, the provision, refresh, or rewind operation will also fail with an error message, and a fault will be created on the VDB.

You can use a pre-script to capture configuration file settings, but not the contents of the soon-to-be recreated VDB; a pre-script executes too late to access the VDB which has already been shut down and unmounted. This makes pre-script functionality much less useful than hook operations like Pre-Refresh.

You can use a post-script to run data transformation operations on newly-provisioned, newly-refreshed, or newly-rewound VDBs. These operations include data masking and setting non-production account passwords in place of cloned production passwords.

 Pre- and post-scripts are an older customization mechanism for SQL Server virtual databases. They have been replaced by hook operations, which have been the standard customization mechanism on all other data platforms.

Pre- and post-scripts are supported for backward compatibility with older versions of the Delphix Engine. Delphix encourages everyone to use Hooks for customizing SQL Server VDBs for future implementations, if possible.

### Associating scripts with a VDB

Pre- and Post-scripts can be associated with a VDB in one of two ways:

During the VDB provisioning process

1. Log in to the **Delphix Management** application/
2. In the top menu bar, click **Manage**.
3. Select **Datasets** to display the SQL Server dSources and VDBs.
4. From the listed **Datasets** in the left-hand navigation bar, select a SQL Server **dSource** or **VDB**.
5. Click the **TimeFlow**.
6. Click **Provision**.
7. In the first **Target Environment** step of the **Provision VDB** wizard, there are fields for **Pre Script** and **Post Script**.
8. Enter the calling syntax of the Windows PowerShell script into either or both of the appropriate fields.

- a. The calling environment is that of the **primary Environment User account**, as shown in the **Environment Details** panel of the Delphix environment (**Manage > Environments**)
- b. Four (4) environment variables will be populated with the name of the VDB, the SQL Server instance name and port, and the SQL Server database name.

After provisioning, using the configuration tab of the Datasets details page

1. In the **Datasets** panel, click the virtual dataset.
2. Click the **Configuration** tab.
3. Within the **Configuration** tab, click the **Hooks** tab.
4. Select the **hook** to edit.
  - a. Click the **Plus** icon to add a new operation.
  - b. Select the **type of operation** or click  to load a hook operation template.
  - c. Click the **text area** and edit the contents of the operation.
  - d. To remove an operation from the list, click the **Trash** icon on the operation.
  - e. When you have set all hook operations, click the **checkmark** to save the changes. The current operations at this hook will be displayed. To edit this list of operations, click the **Pencil** icon in the top right-hand corner of the tab.

### Execution context for SQL server scripts

For VDBs, pre- and post-scripts are executed in the context of the environment user that was selected during the VDB provision and not the primary environment user. The primary environment user can change over time, all VDB operations are done using the user that was initially selected.

### Error handling for SQL server PowerShell scripts

If a pre-script or post-script encounters an unrecoverable error during execution, the Delphix Engine expects the script to return with a non-zero exit code. Otherwise, the error will not be detected.

PowerShell gives you a few ways to handle errors in your scripts:

- Set `undefinedErrorActionPreference`. The allowable values for `$ErrorActionPreference` are:
  - `Continue` (default) – Continue even if there is an error
  - `SilentlyContinue` – Acts like Continue with the exception that errors are not displayed
  - `Inquire` – Prompts the user in case of error
  - `Stop` : Stops execution after the first error
- Use exception handling by using traps and try/catch blocks to detect errors and return with non-zero exit codes

- Use custom error handling that can be invoked after launching each command in the script to correctly detect errors. The following example shows how you can use the function `verifySuccess` to detect whether the previous command failed, and if it did print, print an error message and return with an exit code of **1**.

```
function die {
    Write-Error "Error: $($args[0])"
    exit 1
}
function verifySuccess {
    if (!$?) {
        die "$($args[0])"
    }
}
Write-Output "I'd rather be in Hawaii"
verifySuccess "WRITE_OUTPUT_FAILED"
& C:\Program Files\Delphix\scripts\myscript.ps1
verifySuccess "MY_SCRIPT_FAILED"
```

## Using hostChecker to validate target database servers

### Prerequisites

Make sure that your source and target environments meet the requirements.

### Procedure to validate target environments

1. Verify with your System Administrator that the Delphix Connector has been installed in all Target environments.
2. Login to the Windows target host using the **Windows user account** that the System Administrator configured as a Delphix target user.
3. Open **Windows Powershell** using the **Run as Administrator** option.
4. Execute the **host checker script** by running:

```
<Delphix Connector installation folder>\etc\dlpx-host-checker.ps1
```

5. Select a path where a report file will be saved, such as **C:\temp\delphix-host-checker-report.txt**.
6. Select the **default** option of **Target Host**.
7. Read the output of the checks.
8. The error or warning messages will explain any possible problems and how to address them. Resolve the issues that the HostChecker describes. Do not be surprised or undo your work if more errors appear the next time you run HostChecker; the error you just fixed may have been masking other problems.
9. Repeat steps 4–7 until all the checks return no errors or warnings.

### Tests run

Test	SQL Server Source	SQL Server Target	Description
<b>Check Powershell Version</b>	X	X	Verifies that Powershell 2.0 or greater is installed
<b>Check OS User Privileges</b>	X	X	For target hosts, verifies that the operating system (OS) user has administrative rights. For source hosts, verifies that the OS user can successfully perform remote registry access from the target host to the source host.
<b>Check host settings</b>	X	X	Verifies that the Delphix Engine can discover host environment details from the Windows registry.
<b>Check SQL Server instance discovery</b>	X	X	Verifies that the Delphix Engine can discover SQL Server instances.

Test	SQL Server Source	SQL Server Target	Description
<b>Check SQL Server instance login permission</b>	X	X	For target hosts, verifies that the Windows OS user can be used to log in to the SQL Server instances. For source hosts, verifies that the supplied SQL Server login credentials can be used to log in to the SQL Server instances.
<b>Check database discovery</b>	X	X	Verifies that the Delphix Engine can discover SQL Server databases.

### Additional options

Run the following to view additional HostChecker options:

```
d\px-host-checker.ps1 -?
```

## SAP HANA environments and data sources

**i** Starting 6.0.8.0 and HANA plugin version 6.0.0, Delphix provides you with a vSDK-based solution. **Delphix highly recommends their users to use this HANA Staged (vSDK-based) plugin over the existing HANA Direct (Lua-based) plugin.** Currently, the Lua-based HANA plugin 4.3.1 and earlier versions are also supported. Please refer to [HANA Release Notes](#) for supported versions. For Lua-based HANA plugin documentation, refer to [Delphix Engine 6.0.7.0 Documentation](#) and the earlier versions.

This section covers the following topics:

- [SAP HANA Overview](#)
- [Delphix Architecture](#)
- [SAP HANA 2.0 Plugin Installation](#)
- [SAP HANA 2.0 Plugin Tools](#)
- [Quick Start Guide for HANA plugin](#)
- [SAP HANA Support and Requirements](#)
- [Managing SAP HANA Environments and Hosts](#)
- [Linking Data Sources and Syncing Data with SAP HANA](#)
- [Provisioning and Managing VDBs from SAP HANA dSources](#)
- [SAP HANA Hook Operations](#)

## Delphix architecture

The Delphix HANA plugin is based on a staging architecture, i.e. the linking process and SnapSync requires a staging environment. The staging environment is a HANA DB server host that leverages storage allocated directly on the Delphix Engine using NFS, and it must contain an instance of SAP HANA that is higher or matches the same version of the Source. To create a dSource on a staging server, a full backup would be required. The Recover command deposits its backup data onto the mounted storage area. The Delphix Engine snapshots the Staging server and the snapshots can be provisioned out to one or more target servers.

To create a dSource on a staging server, a full backup of one particular tenant database is required. With this solution, virtualization will be done at the tenant level only. This topic describes the high-level architecture of the Delphix HANA plugin solution.

This solution invokes HANA recovery of database backup files when a user selects to create a dSource on the staging server. The necessary backups/logs are created outside of Delphix and must exist before dSource creation.

Virtual databases can only be provisioned from a dSource (inheriting the state of the dSource).

The following is the high-level Delphix architecture with SAP HANA.

*Delphix for HANA Architecture*

There are two mechanisms to create dSource on the staging server.

- Pull architecture, where the HANA plugin pulls the data into the Delphix provided mount location.
- Staging Push architecture, where the user pushes the data into the Delphix engine.

## HANA plugin with pull architecture

In Delphix HANA with Pull architecture, dSource is created using External backups which must be a HANA Native backup (ie: no support for third-party Backup tools). With External backups, the first dSource snapshot must include a Full backup, but can optionally include one or more incremental or differential backups. Subsequent dSource snapshots can be based upon additional incremental or differential backups (This will require a full backup along with incremental/differential backups, as recovery in Hana always requires a full backup).

HANA plugin supports an External backup, also known as Native Backups. Native backup implies that the backups are written in native storage format to local storage without a third-party backup tool.

The dSource creation operation invokes the HANA database recovery of the relevant HANA backup files. HANA database recovery can be a lengthy process. The duration of recovery time is subject to the size of the database being recovered. After completion of HANA recovery, the HANA instance will contain the newly recovered dSource tenant.

VDB provision operations from a dSource snapshot do not require HANA database recovery and can occur very quickly.

Failure to follow this recommendation diminishes the key value proposition for HANA, which is agility. Below are the recommended tiers:

- **dSource:** A virtual HANA database constructed by recovery.
- **Virtual Database (VDB):** A copy of a specific dSource snapshot, cloned using Delphix technology. These copies are fast to create with a small initial storage footprint. VDBs are the recommended workbench for developers. Multiple VDBs can exist from a single dSource. Each VDB corresponds to a dSource snapshot.

## SAP HANA plugin with staging push architecture

Starting Delphix Engine version 6.0.12.0 and HANA plugin version 6.2.0, a new data ingestion mechanism has been introduced that will help users to push data into the Delphix provided mount point on their own.

The previous versions of the HANA plugin were based only on the Pull approach and it was difficult to support the different ingestion mechanisms as it required a lot of effort to analyze, code, and develop the solution. With the Staging Push mechanism, data ingestion can be achieved with minimum effort.

Few points to be noted about the Staging Push mechanism.

- dSource creation creates an empty mount point on the staging host
- User managed backup and restore

## Operational best practice

- Construct a dSource using the backup files. Construct multiple VDBs descended from the dSource.
- Create a meaningful object name.
- Create Dataset Groups that help delineate to which tier an object belongs.

- Segregate user targets (where VDBs reside) from the staging where HANA recovery must take place to create the dSource.
- Provision end-user VDBs, so that they can be created, refreshed, and rewound quickly.
- Layer VDBs to perform any common post-recovery operations to further streamline provisioning steps.
- Closely monitor and manage the quantity and lifespan of dSource and VDB snapshots, since each can consume additional Delphix storage.

### Benefits of HANA plugin

- Virtualization of individual tenant databases instead of the entire system.
- Ability to mix and match virtualized tenants across any HANA system.
- Reduced Storage footprint. VDBs can use significantly less storage when initially provisioned from dSource.
- Relaxes strict requirement of exact HANA version match between source and target, leveraging HANAs ability to recover an earlier version against a more recent version.
- Source backup files can be ingested from a surrogate host without impact to the true production source host.

### Limitations of HANA plugin

- The tenant's name should contain at least one alphanumeric character or one underscore. Also, it should not start with a digit.
- A single quote, double quote, and space characters are not allowed in the password.
- Datasets created using the Lua version cannot be upgraded to the vSDK version.
- Manual cleanup/unmounting would be required after **force delete** operation on any dataset.

## SAP HANA 2.0 plugin installation

The HANA 2.0 Plugin is provided as a zip file on the Delphix download site. Follow the steps below to download the plugin:

1. In the web browser, go to the Delphix [download](#) site.
2. Login to the download site using email and password credentials.
3. Navigate to the required version number of Delphix Engine.
4. Go to the Plugins > HANA > HANA 2.0 > Plugin\_<version\_number>.zip folder and download the zip file.

For initial and upgrade installations refer to the section [Delphix Engine Plugin Management](#) for further details.

## SAP HANA 2.0 plugin tools

Delphix provides the **create\_backup\_metadata.sh** script, which is bundled with the plugin. This script is required to be executed by customer for customer-created HANA backups, which are to be used to create or refresh a dSource. This script can be found at:

```
<path>/scripts/create_backup_metadata.sh
```

This script must be run prior to creating or refreshing a dSource from a customer-created backup. The script is not required for Delphix-initiated backups. The script must be run on the source instance where the source tenant database exists. The script retrieves and persists important metadata about the specific backup set. This information will be used by the plugin during the dSource creation and will then be stored in the metadata section of the dSource.

### Prerequisites

- The script assumes the user has the credentials of the tenant on the source HANA instance.
- The script must be copied to the source host as the operating system user should have access to hdbsql.
- The script must be executable.
- Correct backup files of the source must exist on the source host or the backup files should be accessible from the source host.
- The script should have the write permissions in the directory where the backups have been kept.

You can run the `create_backup_metadata.sh` script in the following two ways.

1. Interactive mode
2. Providing the complete list of parameters (Non-Interactive mode)

### Interactive mode

The mode allows you to input the values to the required/optional parameters one by one on the CLI. See the sample script run example below the Parameters table.

### Parameters

The following table lists the optional and required parameters used by the script.

Parameter	Optional/Required	Description
Please enter the location of the Backup files:	Required	Location of the Backup files For example: <code>/usr/sap/HDB/HDB00/source_backup</code>

Parameter	Optional/Required	Description
If the above provided location of the Backup files is different than the original location where backups were taken then please enter original location, otherwise press enter(OPTIONAL):	Optional	This is the original location where the backup files were created during the dSource creation which can be used later for recovery purposes  Provide this parameter when the location provided at the " <i>Please enter the location of the Backup files:</i> " parameter is different from the location where the backup files are kept now  For example: <code>/usr/sap/HDB/HDB00/backup/data/DB_TEST1</code>
Please enter the location of the Log files(OPTIONAL):	Optional	Location of the Log files  You may use logs for the recovery  For example: <code>/usr/sap/HDB/HDB00/source_log</code>
If the above provided location of the log files is different than the original location where log files were created then please enter original location, otherwise press enter(OPTIONAL):	Optional	This is the original location where the log files were created during the dSource creation which can be used later for recovery purposes  Provide this parameter when the location provided at the " <i>Please enter the location of the Backup files:</i> " parameter is different from the location where the log files are kept now  For example: <code>/usr/sap/HDB/HDB00/backup/log/DB_TEST1</code> (Note that this is not a valid directory)
Please enter the Tenant Database Name:	Required	Name of the tenant database for which backups/logs were created  For example: TEST1
Please enter the SID of the HANA database:	Required	SID of the tenant database for which backups/logs are present  For example: HDB
Enter the Tenant User Name:	Required	Username to connect to the tenant database  For example: SYSTEM
Tenant User Password:	Required	Password to connect to the tenant database
Please enter the Instance Number:	Required	Instance number of the tenant database  For example: 00

### Example

The following example shows an execution of the script with input parameters:

```

hdbadm@ip-10-110-244-207.delphix:/usr/sap/HDB/HDB00> ./create_backup_metadata.sh
Starting create_backup_metadata.sh
Please enter the location of the Backup files:/usr/sap/HDB/HDB00/source_backup

If the above provided location of the Backup files is different than the original location where backups were taken then please enter original location, otherwise press enter(OPTIONAL):/usr/sap/HDB/HDB00/backup/data/DB_TEST1

Please enter the location of the Log files(OPTIONAL):/usr/sap/HDB/HDB00/backup/log/DB_TEST1

If the above provided location of the log files is different than the original location where log files were created then please enter original location, otherwise press enter(OPTIONAL):

Please enter the Tenant Database Name:TEST1

Please enter the SID of the HANA database:HDB

Please enter the Tenant User Name:SYSTEM

Tenant User Password:

Please enter the Instance Number:00
    
```

### Usage

```
./create_backup_metadata.sh
```

### Providing the complete list of parameters

This mode allows you to input the parameter values in a specified order at the run time. See the sample script run example below the Parameters table.

#### Parameters

The following table lists the optional and required parameters in the order that in which you need to pass the parameter values along with the script.

Parameter	Optional/Required	Description
TENANT_DATABASE_NAME	Required	Tenant database name for which the script needs to be run
SID	Required	SID of the HANA database
TENANT_USER_NAME	Required	Username to connect to the tenant database
TENANT_USER_PASSWORD	Required	Password to connect to the tenant database
INSTANCE_NUMBER	Required	Instance number of the HANA database
DATA_BACKUP_PATH	Required	The location where the backups are present
LOG_BACKUP_PATH	Optional	The location where the logs are present

Parameter	Optional/Required	Description
ORIG_DATA_BACKUP	Optional	Original location where these backups were created. Do not provide any value if backups are present at the same location where they were created
ORIG_LOG_BACKUP_PATH	Optional	Original location where logs were created. Do not provide any value if the logs are present at the same location where they were created

### Example 1

The following example shows an execution of the script with input parameter values in the above-specified order.

```
hdbadm@target:/usr/sap/HDB/HDB00> ./create_backup_metadata.sh TEST HDB SYSTEM Delphix_123 00 /usr/sap/HDB/HDB00/source_backup
Starting create_backup_metadata.sh
Checking : /usr/sap/HDB/HDB00/source_backup
```

```
Running the script for TEST tenant
BACKUP ID of latest complete backup: 1633404668463
Metadata information of backup is stored in file: /usr/sap/HDB/HDB00/source_backup/backupTimeInfo
```

If all the mandatory parameters are not provided or parameters are not provided in the specified order, then the plugin will throw an error.

### Example 2

The following example shows an error when all the mandatory parameter values are not provided.

```
hdbadm@target:/usr/sap/HDB/HDB00> ./create_backup_metadata.sh TEST HDB SYSTEM Delphix_123
Starting create_backup_metadata.sh

Incorrect number of parameters provided to the script. Please provide the below parameters to the script or do not pass any parameters which will invoke the script in interactive mode.

TENANT_DATABASE_NAME - Tenant Database name for which script needs to be run.
SID - SID of the HANA Database
TENANT_USER_NAME - User name to connect to the Tenant Database
TENANT_USER_PASSWORD - Password to connect to the Tenant Database
INSTANCE_NUMBER - Instance number of the HANA Database
DATA_BACKUP_PATH - Location where backups are present
LOG_BACKUP_PATH - Location where logs are present. This is an optional field.
ORIG_DATA_BACKUP - Original location where these backups were created. This is an optional field. Do not provide any value if Backups are present at the same location where they were created.
ORIG_LOG_BACKUP_PATH - Original location where logs were created. This is an optional field. Do not provide any value if Logs are present at same location
```

## Quick start guide for SAP HANA plugin

This quick start guide, which is excerpted from the larger User Guide, is intended to provide you with a quick overview of working with HANA database objects in the Delphix Engine. It does not cover any advanced configuration options or best practices, which can have a significant impact on performance. It assumes that you are working in a Lab/Dev setting and attempting to quickly test Delphix functionality. It assumes you will use the VMware Hypervisor.

### Overview

In this guide, we will walk through deploying a Delphix Engine, starting with configuring Source and Target database environments on Windows servers. We will then create a dSource, and provision a VDB.

For purposes of the QuickStart, you can ignore any references to Replication or Masking.

### Deploy OVA on VMware

Use the Delphix-supplied OVA file to install the Delphix Engine. The OVA file is configured with many of the minimum system requirements. The underlying storage for the install is assumed to be redundant SAN storage.

1. Download the OVA file from <https://download.delphix.com>. You will need a support login from your sales team or a welcome letter.
  - a. Navigate to the Delphix Product Releases/<Current Version>/Appliance Images page.
2. Login using the vSphere client to the vSphere server (or vCenter Server) where you want to install the Delphix Engine.
3. In the vSphere Client, click **File**.
4. Select **Deploy OVA Template**.
5. Browse to the OVA file.
6. Click **Next**.
7. Select a **hostname** for the Delphix Engine. This hostname will also be used in configuring the Delphix Engine network.
8. Select the **data center** where the Delphix Engine will be located.
9. Select the **cluster** and the **ESX host**.
10. Select one (1) **data store** for the **Delphix OS**. This datastore can be **thin-provisioned** and must have enough free space to accommodate the 127GB comprising the Delphix operating system.
11. Select four (4) or more **data stores** for Database Storage for the Delphix Engine. The Delphix Engine will stripe all of the Database Storage across these VMDKs, so for optimal I/O performance, each VMDK must be equal in size and be configured **Thick Provisioned - Eager Zeroed**. Additionally, these VMDKs should be distributed as evenly as possible across all four SCSI I/O controllers.
12. Select the **virtual network** you want to use. If using multiple physical NICs for link aggregation, you must use vSphere NIC teaming. Do not add multiple virtual NICs to the Delphix Engine itself. The Delphix Engine should use a single virtual network. For more information, see [Optimal Network Architecture for the Delphix Engine](#)
13. Click **Finish**. The installation will begin and the Delphix Engine will be created in the location you specified.
14. Once the installation has completed, power on the Delphix Engine and proceed with the initial system configuration as described in [Setting Up Network Access to the Delphix Engine](#)

If your source database is 4 TB, you probably need 4 TB of storage for the Delphix Engine. Add at least 4 data disks of similar size for the Delphix VM. For example: for a source database of 4 TB, create 4 VMDKs of 1 TB each.

 For a full list of requirements and best practice recommendations, see [Virtual Machine Requirements for VMware Platform](#)

## Setup network access to the Delphix engine

1. Power on the Delphix Engine and open the Console.
2. Wait for the Delphix Management Service and Delphix Boot Service to come online. This might take up to 10 minutes during the first boot. Wait for the large orange box to turn green.
3. Press any key to access the sysadmin console.
4. Enter `sysadmin@SYSTEM` for the username and `sysadmin` for the password.
5. You will be presented with a description of available network settings and instructions for editing.

### Delphix Engine Network Setup

To access the system setup through the browser, the system must first be configured **for** networking in your environment. From here, you can configure the primary **interface**, DNS, hostname, and **default** route. When DHCP is configured, all other properties are derived from DHCP settings.

To see the current settings, run `"get."` To change a property, run `"set =."` To commit your changes, run `"commit."` To exit **this** setup and **return** to the standard CLI, run `"discard."`

`defaultRoute` IP address of the gateway **for** the **default** route -- **for** example, `"1.2.3.4."`

`dhcp` Boolean value indicating whether DHCP should be used **for** the primary **interface**. Setting **this** value to `"true"` will cause all other properties (address, hostname, and DNS) to be derived from the DHCP response

`dnsDomain` DNS Domain -- **for** example, `"delphix.com"`

`dnsServers` DNS server(s) as a list of IP addresses -- **for** example, `"1.2.3.4,5.6.7.8."`

`hostname` Canonical system hostname, used in alert and other logs -- **for** example, `"myserver"`

`primaryAddress` Static address **for** the primary **interface** in CIDR notation -- **for** example, `"1.2.3.4/22"`

Current settings:

```
defaultRoute: 192.168.1.1
dhcp: false
dnsDomain: example.com
```

```
dnsServers: 192.168.1.1
hostname: Delphix
primaryAddress: 192.168.1.100/24
```

- Configure the `hostname` . If you are using DHCP, you can skip this step.

```
delphix network setup update *> set hostname=<hostname>
```

**Note:**

Use the same `hostname` you entered during the server installation.

- Configure DNS. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set dnsDomain=<domain>
delphix network setup update *> set dnsServers=<server1-ip>[,<server2-ip>,...]
```

- Configure either a static or DHCP address.  
DHCP Configuration

```
delphix network setup update *> set dhcp=true
```

## Static Configuration

```
delphix network setup update *> set dhcp=false
delphix network setup update *> set primaryAddress=<address>/<prefix-len>
```

**Note:**

The static IP address must be specified in CIDR notation (for example, `192.168.1.2/24` )

- Configure a default gateway. If you are using DHCP, you can skip this step.

```
delphix network setup update *> set defaultRoute=<gateway-ip>
```

- Commit your changes. Note that you can use the `get` command prior to committing to verify your desired configuration.

```
delphix network setup update *> commit
Successfully committed network settings. Further setup can be done through the
browser at:
```

```
http://<address>
```

Type "exit" to disconnect, or any other commands to **continue** using the CLI.

- Check that you can now access the Delphix Engine through a Web browser by navigating to the displayed IP address, or hostname if using DNS.
- Exit setup.

```
delphix> exit
```

## Setting up the Delphix engine

Once you set up the network access for Delphix Engine, navigate to the Delphix Engine URL in your browser for server setup.

The welcome screen below will appear for you to begin your Delphix Engine setup.

**DELPHIX SETUP** Setup Help

### Virtualization Setup

**Welcome**

Choose engine type to setup:

Virtualization  
 Masking

This wizard will step you through the setup. During this process you will complete the following:

- Create your password for the default "sysadmin" user
- Set the system time
- Configure network and services
- Configure the storage pool
- Configure proxies, SMTP, and LDAP (these are optional)
- Register your software

After setup is complete, you will have two administrators defined:

- The system administrator, "**sysadmin**" with the password you defined. This will be the system administrator for the instance.
- The engine administrator, "**admin**" with the password you defined. This is typically a DBA who will administer all the data managed by the instance.

When setup is complete, log in as engine administrator to begin using your engine.

Back **Next** Submit

The setup procedure uses a wizard process to take you through a set of configuration screens:

- Administrators
- Time
- Network
- Network Security
- Storage
- Outbound Connectivity
- Authentication
- Network Authorization
- Registration
- Summary

1. Connect to the Delphix Engine at <http://<Delphix Engine>login/index.html#serverSetup> . The **Delphix Setup** application will launch when you connect to the server.

Enter your **sysadmin** login credentials, which initially defaults to the username **sysadmin**, with the initial default password of **sysadmin**. On first login, you will be prompted to change the initial default password.

2. Click **Next**.

## Administrators

The Delphix Engine supports two types of administrators:

- System Administrator (**sysadmin**) - this is the engine system administrator. The sysadmin password is defined here.
- Engine Administrator (**admin**) - this is typically a DBA who will administer all the data managed by the engine.

On the Administrators tab, you set up the sysadmin password by entering an email address and password. The details for the admin are displayed for reference.

The default domain user created on Delphix Engines from 5.3.1 is known as **admin** instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then disabling the delphix\_admin.

## Time

The engine time is used as the baseline for setting policies that coordinate between virtual databases and external applications

Choose your option to setup system time in this section. For a Quick Start, simply set the time and your timezone. You can change this later.

## Network

The initial out-of-the-box network configuration in the OVA file is set to use a single VMXNET3 network adapter.

You have already configured this in the initial configuration. Delphix supports more advanced configurations, but you can enable those later.

## Storage

You should see the data storage VMDKs or RDMs you created during the OVA installation. Click **Next** to configure these for data storage.

## Serviceability

Choose your options to configure serviceability settings.

For a Quick Start, accept the defaults. You can change this later.

## Authentication service

Choose your options to configure authentication services.

For a Quick Start, accept the defaults. You can change this later.

## Registration

If the Delphix Engine has access to the external Internet (either directly or through a web proxy), then you can auto-register the Delphix Engine:

1. Enter your **Support Username** and **Support Password**.

2. Click **Register**.

If external connectivity is not immediately available, you must perform manual registration.

1. Copy the **Delphix Engine registration code** in one of two ways:
  - a. Manually highlight the registration code and copy it to clipboard. Or,
  - b. Click **Copy Registration Code to Clipboard**.
2. Transfer the Delphix Engine's registration code to a workstation with access to the external network Internet. For example, you could e-mail the registration code to an externally accessible e-mail account.
3. On a machine with access to the external Internet, please use your browser to navigate to the Delphix Registration Portal at <http://register.delphix.com>.
4. Login with your Delphix support credentials (username and password).
5. Paste the **Registration Code**.
6. Click **Register**.

 Although your Delphix Engine will work without registration, we strongly recommend that you register each engine as part of the setup. Failing to register the Delphix Engine will impact its supportability and security in future versions.

To regenerate the registration code for a Delphix Engine please refer to, [Regenerating the Delphix Engine Registration Code](#). Delphix strongly recommends that you regenerate this code and re-register the engine regularly to maximize the Support Security of the Delphix Engine. Delphix recommends doing this every six months.

### Summary

The final summary tab will enable you to review your configurations for System Time, Network, Storage, Serviceability, and Authentication.

1. Click the **Back** button to go back and to change the configuration for any of these server settings.
2. If you are ready to proceed, then click **Submit**.
3. Click **Yes** to confirm that you want to save the configuration.
4. Click **Setup** to acknowledge the successful configuration.
5. There will be a wait of several minutes as the Delphix Engine completes the configuration.

### Requirements for HANA staging/target host and databases

Backup of the tenant must be present which needs to be recovered. Along with backup, metadata information generated by script `create_backup_metadata.sh` is also expected in the backup location. As we will be recovering a tenant through backup files the important thing while creating the dSource which should be taken care of is the user should have access to the backup directory where the backup file resides.

#### General staging Host Requirements

- HANA database must be installed and running.
- Read-write permission on the backup directory.
- There must be an operating system user which has HANA administrative user privileges <sid>adm:
  - The Delphix Engine must be able to make an SSH connection to the staging environment using the operating system user.
  - The operating system user must have read and execute privileges on the HANA binaries installed on the staging environment.
  - The operating system user must have read, write, and execute access to the HANA data directories on the staging environment.
- A plugin directory must exist on the staging host. The directory must have the following properties:
  - Should be writable by the operating system user described above.
  - Should have at least 256 MB of available storage.

- TCP/IP connectivity to and from the staging environment must be configured as described in [General Network and Connectivity Requirements](#)
- Hostname and IP address must be correctly configured.

## Requirements for HANA target host and databases

A **target environment** is where virtualized databases run. A target environment must have a HANA instance installed and configured. The VDB will become a tenant on the target database instance.

### General target environment requirements

1. The operating system of the target environment must match the staging environment.
2. The SAP HANA installation on the target environment must have the same or higher version than the staging environment.
3. There must be an operating system user with the following privileges:
  - a. The Delphix Engine must be able to make an SSH connection to the target environment using the operating system user.
  - b. The operating system user must have read and execute privileges on the HANA binaries installed on the target environment.
  - c. The operating system user must have permission to run mount and unmount as the superuser via sudo with neither a password nor a TTY. See [Sudo Requirements for the HANA 2.0 Plugin](#)
4. Prior to the discovery, a plugin directory on the target environment must exist with the following properties:
  - a. The plugin directory must be writable by the operating system user mentioned above.
  - b. The plugin directory must have at least 256 MB of available storage.
5. There must be a mount point directory (for example, /mnt) that will be used as the base for mount points that are created when provisioning a VDB with the following properties:
  - a. The mount point directory must be writable by the operating system user mentioned above.
  - b. The mount point directory should be empty.
6. TCP/IP connectivity to and from the source environment must be configured as described in [General Network and Connectivity Requirements](#).
7. The hostname and IP address must be correctly configured.
8. HANA instance on which the VDB creation is being done should have the empty ports to host the services for the tenant database. The default port number range for tenant databases is 3<instance>40–3<instance>99. This means that the maximum number of tenant databases that can be created per instance is 20. However, you can increase this by reserving the port numbers of further instances. You do this by configuring the property [multidb] reserved\_instance\_numbers in the global.ini file. The default value of this property is 0. If you change the value to 1, the port numbers of one further instance are available (for example, 30040–30199 if the first instance is 00). If you change it to 2, the port numbers of two further instances are available (for example, 30040–30299 if the first instance is 00). And so on.

## Adding a HANA environment

### Prerequisites

- Make sure that the HANA environment in question meets the requirements described in [Requirements for HANA Staging Hosts and Databases](#) and [Requirements for HANA Target Hosts and Databases](#)

### Procedure

- Log in to the **Delphix Management** application.
- Click **Manage**.
- Select **Environments**.

- Next to **Environments**, click the **Actions (...)** menu and select **Add Environment**.
- In the Add Environment dialog, In the **Host OS** select **Unix/Linux** on the menu.
- In **Server Type**, select **Standalone Host**.
- Click **Next**.
- Enter **Name** for the environment.
- Enter the **Host IP address** or **fully qualified hostname**.
- Enter the **SSH port**. The default value is 22.
- Enter an **OS Username** for the environment which should be “.>.>
- Select **Login Type**.

**Note:**

Currently, the Enterprise Password Vault option is not supported.

- Username and Password - enter the OS username and password
- Username and Public Key - enter the OS username.
- Password Vault - select from an existing Enterprise Password Vault

### **i** Using public key authentication

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

1. Select **Public Key** for the **Login Type**.
2. Click **View Public Key**.
3. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - a. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - b. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - c. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See [Option 2 in this CLI Cookbook article](#) for instructions.

1. For Password, enter the password associated with the user in step 11.
2. Select **Public Key** for the **Login Type**.
3. Click **View Public Key**.
4. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - a. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - b. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - c. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.
5. For Password Login, click 'Validate' to test the username and password.
6. Enter a **Plugin Path**. The location specified must be a string without spaces. Ensure this directory path exists on the host in question. Environment discovery will fail if the directory does not exist on the host.
7. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
8. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**. For more information, see [Providing Your Own Oracle Java](#)
9. Click **Submit**. On success, the new environment will be added to the list in the Environments tab.
10. Select the “Databases” tab to view discovered HANA databases:

[Add dSource](#)

## Linking a HANA data source

This topic describes basic concepts behind the creation of a dSource for a HANA database using conventional pull and Staging push mechanisms.

 For Staging Push, only native/third-party backups are used to populate data in the staging database.

For Third-party Backups, users need to provide a “Backup Path” containing FULL and Incremental backups. These files will be copied to the Delphix Engine during the dSource linking process. In this scenario, the Delphix Engine will not require any credentials of the source database. Although credentials for the tenant database (for which backup has been placed) and systemdb of staging instances would be required.

## Prerequisites for customer provided backups ingestion mechanism

- Users need to run the create\_backup\_metadata.sh. This script will create the backupTimeInfo file at the same location where backups are kept. This script will gather all the required metadata information and will store that information in the backupTimeInfo file. This information will then get used by the plugin at the time of creating dSource.
- More details regarding the script have been included in the [HANA 2.0 Plugin Tools](#)

## Procedure

1. Login to the Delphix Management application.

2. Select **Manage > Environments**. Then select the Datasets tab.

3. Create a source configuration on which to build the dSource. You can do this by clicking on the + symbol. The Source configuration can have any name.

4. In the **Add dSource** wizard, select the required source configuration.

5. After selecting the source, below are the parameters required to create the dSource.

a. Parameters required for the conventional **pull** mechanism:

- i. Mount Location on Staging Host
- ii. SAP HANA Source Tenant Database Name
- iii. Source SystemDB User Name
- iv. Source SystemDB Password
- v. Source Tenant Database User Name
- vi. Source Tenant Database Password
- vii. Customer Provided Data Backup Location: This represents the path to the location of the customer-provided backup files.
- viii. Customer Provided Log Backup Location: This represents the path to log the location of the customer-provided log backup files. This parameter is optional.

b. Parameters required for the **Staging push** mechanism

- i. Mount Location on Staging Host
- ii. SAP HANA Source Tenant Database Name
- iii. Enable the **Staging Push** feature by selecting the checkbox "**Use Staging Push**". With this feature, the user handles the Source Tenant database and its state on their own and you don't

need to specify any other staging database parameters, data backup, and log backup locations. If this check box is selected, the HANA plugin will not invoke the tenant creation and recovery operation and if this checkbox is not selected then the default pull approach will be used.

c. Click **Next**.

6. Enter a name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
7. Configure the SnapSync and Retention Policy. The SnapSync policy can be set to 'None' for customers who wish not to run a scheduled SnapSync job.
8. Optionally, users can provide the bash script as a plugin-defined hook. Both Pre-Snapshot and Post-SnapShot hooks can be used.
9. Select **Next**.
10. At the end of the workflow, review the dSource Configuration in the Summary pane as shown below:

Once the dSource linking job is submitted it is possible to monitor progress by selecting **Active Jobs** in the top menu bar. On successful completion, the new dSource will be visible in the list of Datasets under its assigned group.

After dSource creation using the Staging Push mechanism, an empty snapshot will be created but users can not create VDB's from the same. Also, before creating the subsequent snapshots, users will have to create the database and point the database to use the Delphix provided mount point.

## Provisioning a HANA VDB

### Prerequisites

- The provision requires a linked dSource built off a physical source tenant, as described in [Linking a HANA dSource](#), or a VDB.
- The HANA target environment should adhere to the [Requirements for HANA Hosts and Databases](#)
- Operating system users and database users should be configured.

### VDB creation UI

The screenshot shows the 'Target Configuration' pane in the VDB creation UI. On the left, a navigation menu lists: Target Environment, Target Configuration (selected), Configuration, Policies, Masking, Hooks, and Summary. The main area contains the following fields and sections:

- NFS Mount Location\***: Mount Location on Target Host
- SAP HANA Target Tenant Database Name\***: The name of the HANA Target Database to be created
- Target SystemDB User Name\***
- Target SystemDB Password\***: Double quote, single quote or space characters are not valid.
- Target Tenant Database ADMIN User Name\***: The HANA admin user which will be recovered from the source database
- Target Tenant Database ADMIN Password\***: The admin user password for the target database which will be provisioned from the source database. Double quote, single quote or space characters are not valid.
- Configure Tenants Service and Port**:
 

Tenant Database Level Information	Actions
Tenant service and port number* <b>instance30043</b>	Delete
Tenant service and port information separated by a ":". For example: instance_name:port	
Tenant service and port number* <b>xmengine30043</b>	Delete
Tenant service and port information separated by a ":". For example: instance_name:port	

At the bottom of the pane are buttons for Cancel, Back, Next, and Submit.

### Procedure

1. Log in to the **Delphix Management** application.
  2. Click **Manage**.
  3. Select **Datasets**.
  4. Select a **dSource**.
  5. Select a **snapshot** from which you want to provision.
- Note:**  
If the first or empty dSource Snapshot that was created using the Staging Push mechanism is detected by the plugin and an error message is displayed. This check is done for every VDB creation operation.
6. Click the **Provision VDB** icon to open the Provision VDB wizard.
  7. Select a target environment from the left pane.
  8. The HANA 2.0 Plugin supports one installation on the same host, hence the value in the **Installation** dropdown will be already populated. Multiple drop-down options should not be available.
  9. Set the **Environment User** to be the Instance Owner. Note: The picking of instance owner is only possible if you have multiple environment users set on that host.
  10. Click **Next**.
  11. Target Configuration pane you will need to specify the following:

**Note:**

**\*!** indicates the mandatory fields.

- a. **NFS Mount Location\***: Delphix recommends setting the trailing directory to match the VDB name to delineate mount points and support administration and troubleshooting. In the example shown, the **NFS Mount Location** is /mnt/provision/dev where dev matches the **SAP HANA Target Tenant Database Name**.
- b. **SAP HANA Target Tenant Database Name\***: This refers to the target tenant database name which will be created upon VDB creation.
- c. **Target SystemDB User Name\***: This refers to the SystemDB username in the target database.
- d. **Target SystemDB Password\***: This refers to the SystemDB password in the target database.
- e. **Target Tenant Database ADMIN User Name\***: This refers to the username of the tenant system user.

- f. Target Tenant Database ADMIN Password\*: This refers to the password of the tenant system user.

**Note:**

The SYSTEM username and password derived from the physical source database should be entered during the provision of a VDB because those credentials will be recovered during provision.

- g. Configure Tenants Service and Port: This refers to the list of tenant services and port numbers in the following format.

```
<service>:<port>
For example, indexserver:30043
```

You can click "+Add" to add more services.

**Note:**

- This is not a mandatory field. If a user doesn't provide a value to this, then the plugin will proceed with the above fields and it will allocate the service and port on its own.
- If an invalid service is provided, the plugin will proceed with input, but will eventually fail while creating the service and will display an error on the Delphix Engine UI.

- In the configuration section
  - Set the vFile Name or accept the default, which is a random string. Delphix strongly recommends applying a consistent naming convention. We suggest this name should match the Target Tenant Name from the previous pane. Maintaining a consistent naming convention will support administration and troubleshooting activities. In the example shown, the vFile Name "dev" matches the actual tenant name and mount point from the previous pane.
  - Select a **Target Group** for the VDB. Click the **Add Dataset Group** icon to add a new group if required.
  - Set **Auto VDB Restart** option to automatically restart the VDB, where the target host is rebooted. Delphix recommends enabling this setting.
- Click **Next**.
- VDB **Snapshot Policy**. Select the Snapshot policy if an automated VDB snapshot schedule is required. Optionally, the Snapshot policy may be disabled by selecting "None".
- Click **Next**.
- Masking**. This page offers the opportunity to link the provision job to a masking job.
- Hooks**. Run a customized shell script via a hook operation at a particular moment in the provision operation.
- Click **Next**.
- Summary**. Presents an opportunity to review all the information as a part of the initial provision workflow.
- Click **Submit**. Once a provision job is submitted it is possible to monitor its progress by selecting "Active Jobs" in the top menu bar. On successful completion, VDB will be visible in the list of Datasets under its assigned group.

## Next steps

Congratulations! You have provisioned your first virtual database!

Now, perform some simple functional tests with your application. You can connect your app to the VDB using standard TNS/JDBC techniques. Delphix has already registered the VDB for you on the target listener.

We suggest the following next steps:

1. Drop a table and use the VDB Rewind feature to test the recovery of your VDB.
2. Take a snapshot of your dSource and refresh your VDB to quickly get fresh production data.
3. Provision a new VDB from your VDB to test the sharing data quickly with other teams.
4. Mask your new VDB to protect sensitive data. Provision of new VDBs from that masked VDB to quickly provide safe data to development and QA teams.

## SAP HANA support/compatibility matrix

This section describes the HANA (DBMS) versions that are supported by the HANA 2.0 Plugin, as well as the compatible operating systems (OS), for use on the source and target environments.

**⚠** Delphix Support Policies specifically list Major and Minor release coverage. If a minor release is listed as covered, then all patch releases under that minor release are certified.

### Supported DBMS Version

HANA Version (Standard and Enterprise Editions)	Support Package Stack (STS)
2.0	04
2.0	05

**Important**  
A target may have a higher SPS release than a source; the reverse is not supported.

### Key:

Color	Supported?
Y	Yes
N	No

### Supported Operating System

Supported OS Version	Supported DBMS Version	
	HANA 2.0 SPS 04 (Standard and Enterprise Editions)	HANA 2.0 SPS 05 (Standard and Enterprise Editions)
RHEL 7.9	Y	Y
RHEL 8.1	Y	Y
RHEL 7.3/7.4/7.5	Y	N

RHEL 7.6	Y	Y
SUSE 12 SP 03	Y	N
SUSE 15 SP 02	N	Y

Plugin/Delphix Engine Compatibility

The plugin should be installed on compatible Delphix Engines per the table below:

Delphix Engine	vSDK-based Plugin													
	4.1.1	4.1.2	4.2.0	4.3.0	4.3.1	4.3.2	6.0.0	6.0.1	6.1.0	6.1.1	6.2.0	6.2.1	6.3.0	6.3.1
6.0.0.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.1.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.2.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.3.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.4.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.5.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.6.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.7.x	Y	Y	Y	Y	Y	Y	N	N	N	N	N	N	N	N
6.0.8.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N	N	N
6.0.9.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N	N	N
6.0.10.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N	N	N

							vSDK-based Plugin								
6.0.11.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N	N	N
6.0.12.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
6.0.13.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
6.0.14.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
6.0.15.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
6.0.16.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
6.0.17.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
7.0.0.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
8.0.0.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
9.0.0.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
10.0.0.x	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

Unsupported Features

- Multiple duplicate services are not supported in this release.
- Point-in-Time recovery of the HANA database is not possible.
- HANA 1.0 MDC and SDC configurations are not supported.
- Scale-out source and target environments are not supported.
- High isolation mode is not supported with this release.
- Partitioning is not supported with this release.
- V2P is not supported with this release.
- Although the staging Push solution is generic and should work with HSR. But for this release, we have not validated the solution with HANA Streaming Replication(HSR).
- Third-party backups tools are not supported with Pull based ingestion mechanism.
- More than one instance of the same HANA service is not supported with this release.

- Switching between the Staging Push to Pull model is not supported with this release.

## Requirements for SAP HANA staging hosts and databases

Backup of the tenant must be present which needs to be recovered. Along with backup, metadata information generated by script `create_backup_metadata.sh` is also expected in the backup location. As we will be recovering a tenant through backup files the important thing while creating the dSource which should be taken care of is the user should have access to the backup directory where the backup file resides.

### General staging Host Requirements

- HANA database must be installed and running.
- Read-write permission on the backup directory.
- There must be an operating system user which has HANA administrative user privileges :
  - The Delphix Engine must be able to make an SSH connection to the staging environment using the operating system user.
  - The operating system user must have read and execute privileges on the HANA binaries installed on the staging environment.
  - The operating system user must have read, write, and execute access to the HANA data directories on the staging environment.
- A plugin directory must exist on the staging host. The directory must have the following properties:
  - Should be writable by the operating system user described above.
  - Should have at least 256 MB of available storage.
- TCP/IP connectivity to and from the staging environment must be configured as described in [General Network and Connectivity Requirements](#)
- Hostname and IP address must be correctly configured.

 Non-database users/Low Privileged users/Users for which privileges need to be elevated, are not supported for performing Delphix operations.

## Requirements for SAP HANA target hosts and databases

This section describes user privileges and other requirements for HANA target hosts and databases collectively referred to as the target environment.

A **target environment** is where virtualized databases run. A target environment must have a HANA instance installed and configured. The VDB will become a tenant on the target database instance.

### General target environment requirements

1. The operating system of the target environment must match the staging environment.
2. The SAP HANA installation on the target environment must have the same or higher version than the staging environment.
3. There must be an operating system user with the following privileges:
  - a. The Delphix Engine must be able to make an SSH connection to the target environment using the operating system user.
  - b. The operating system user must have read and execute privileges on the HANA binaries installed on the target environment.
  - c. The operating system user must have permission to run mount and unmount as the superuser via sudo with neither a password nor a TTY. See [Sudo Requirements for the HANA 2.0 Plugin](#)
4. Prior to the discovery, a plugin directory on the target environment must exist with the following properties:
  - a. The plugin directory must be writable by the operating system user mentioned above.
  - b. The plugin directory must have at least 256 MB of available storage.
5. There must be a mount point directory (for example, /mnt) that will be used as the base for mount points that are created when provisioning a VDB with the following properties:
  - a. The mount point directory must be writable by the operating system user mentioned above.
  - b. The mount point directory should be empty.
6. TCP/IP connectivity to and from the source environment must be configured as described in [General Network and Connectivity Requirements](#).
7. The hostname and IP address must be correctly configured.
8. HANA instance on which the VDB creation is being done should have the empty ports to host the services for the tenant database. The default port number range for tenant databases is 3<instance>40–3<instance>99. This means that the maximum number of tenant databases that can be created per instance is 20. However, you can increase this by reserving the port numbers of further instances. You do this by configuring the property [multidb] reserved\_instance\_numbers in the global.ini file. The default value of this property is 0. If you change the value to 1, the port numbers of one further instance are available (for example, 30040–30199 if the first instance is 00). If you change it to 2, the port numbers of two further instances are available (for example, 30040–30299 if the first instance is 00). And so on.

 Non-database users/Low Privileged users/Users for which privileges need to be elevated, are not supported for performing Delphix operations.

## Network and connectivity requirements for SAP HANA environments

Please see [General Network and Connectivity Requirements](#) and [Architecture Best Practices for Network Configuration](#) for detailed network and connectivity requirements for the Delphix Engine, including connection requirements, port allocation, and firewall and Intrusion Detection System (IDS) considerations.

## Sudo requirements for the SAP HANA 2.0 plugin

The following sudo privileges are requirements for the HANA 2.0 Plugin.

Privilege	Source	Target	Rationale
mkdir/rmdir	Not Required	Required	Delphix dynamically makes and removes directories under the provisioning directory during VDB operations. This privilege is optional, provided the provisioning directory permissions allow the delphix os user to make and remove directories.
mount/umount	Not Required	Required	Delphix dynamically mounts and unmounts directories under the provisioning directory during VDB operations. This privilege is required because <code>mount</code> and <code>umount</code> are typically reserved for superuser.

It is required to specify the NOPASSWD qualifier within the "sudo" configuration file. This ensures that the "sudo" command does not demand the entry of a password.

Example with user hdbadm

```
Defaults:hdbadm !requiretty
hdbadm ALL=NOPASSWD:/sbin/mount, /sbin/umount, /bin/mkdir, /bin/rmdir
```

Example of limiting `sudo` access for the Delphix OS user

In situations where security requirements prohibit giving the Delphix user root privileges to mount, unmount, make directory, and remove directory on the global level, it is possible to configure the `sudoers` file to provide these privileges only on specific mount points or from specific Delphix Engines, as shown in the below example.

```
Defaults:hdbadm !requiretty
hdbadm ALL=(root) NOPASSWD: \
/bin/mount * <delphix-server-name>* /mnt/provision/*, \
/bin/umount /mnt/provision/*, \
/bin/mkdir * /mnt/*
```

 that the following example is for illustrative purposes and the sudo file configuration options are subject to change.

Example 1

This example restricts the `delphix_os` user's use of `sudo` privileges to the directory `/hana`.

Note that wildcards are allowed for the options on `mount` and `umount` because those commands expect a fixed number of arguments after the options. The option wildcard on the `mount` command also makes it possible to specify the file-system being mounted from the Delphix Engine.

However, wildcards are not acceptable on `mkdir` and `rmdir` because they can have any number of arguments after the options. For those commands, you must specify the exact options ( `-p` , `-p -m 755` ) used by the Delphix Engine.

Example `/etc/sudoers` File Configuration on the Target Environment for sudo Privileges on the VDB Mount Directory Only (Linux OS)

```
Defaults:delphix_os !requiretty
delphix_os ALL=(root) NOPASSWD: \
/bin/mount * /hana/*, \
/bin/umount * /hana/*, \
/bin/umount /hana/*, \
/bin/mkdir -p /hana/*, \
/bin/mkdir -p -m 755 /hana/*, \
/bin/mkdir /hana/*, \
/bin/rmdir /hana/*
```

#### Example 2

This example restricts the **delphix\_os** user's use of `sudo` privileges to the directory `/hana` , restricts the mount commands to a specific Delphix Engine hostname and IP, and does not allow user-specified options for the `umount` command.

This configuration is more secure, but there is a tradeoff with deployment simplicity. This approach would require a different sudo configuration for targets configured for different Delphix Engines.

A Second Example of Configuring the `/etc/sudoers` File on the Target Environment for Privileges on the VDB Mount Directory Only, and Allows Mounting Only from a Single Server (Linux OS)

```
Defaults:delphix_os !requiretty
delphix_os ALL=(root) NOPASSWD: \
/bin/mount <delphix-server-name>* /hana/*, \
/bin/mount * <delphix-server-name>* /hana/*, \
/bin/mount <delphix-server-ip>* /hana/*, \
/bin/mount * <delphix-server-ip>* /hana/*, \
/bin/mount "", \
/bin/umount /hana/*, \
/bin/umount * /hana/*, \
/bin/mkdir [*] /hana/*, \
/bin/mkdir /hana/*, \
/bin/mkdir -p /hana/*, \
/bin/mkdir -p -m 755 /hana/*, \
/bin/rmdir /hana/*
```

## Workflow for SAP HANA environments

A staging environment must be added to the Delphix Engine before linking. Similarly, a compatible target environment must be added to the Delphix Engine in order to provide a location to provision to.

Installation of the HANA Plugin is required before the discovery of a HANA environment can occur.

Once an environment is added to the Delphix Engine, environment discovery takes place. Environment discovery is a process that enables the HANA Plugin to determine HANA installation details on a host. The same Environment Discovery process can be repeated during an Environment Refresh in order to detect new HANA installations.

## Adding a SAP HANA environment

This topic describes how to add a HANA environment.

### Prerequisites

- Make sure that the HANA environment in question meets the requirements described in [Requirements for HANA Staging Hosts and Databases](#) and [Requirements for HANA Target Hosts and Databases](#)

### Procedure

- Login to the **Delphix Management** application.
- Click **Manage**.
- Select **Environments**.
- Next to **Environments**, click the **Actions (...) menu and** select **Add Environment**.
- In the Add Environment dialog, In the **Host OS** select **Unix/Linux** on the menu.
- In **Server Type**, select **Standalone Host**.
- Click **Next**.
- Enter **Name** for the environment.
- Enter the **Host IP address** or **fully qualified hostname**.
- Enter the **SSH port**. The default value is 22.
- Enter an **OS Username** for the environment which should be “.>”.>
- Select **Login Type**.

#### Note:

- Currently, the Enterprise Password Vault option is not supported.
- Username and Password - enter the OS username and password
- Username and Public Key - enter the OS username.
- Password Vault - select from an existing Enterprise Password Vault

#### Using public key authentication

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

1. Select **Public Key** for the **Login Type**.
2. Click **View Public Key**.
3. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  - a. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - b. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - c. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI. See [CLI Cookbook: VDBs](#) for instructions.

1. For Password, enter the password associated with the user in step 11.
2. Select **Public Key** for the **Login Type**.
3. Click **View Public Key**.
4. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.

- a. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  - b. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  - c. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.
5. For Password Login, click 'Validate' to test the username and password.
  6. Enter a **Plugin Path**. The location specified must be a string without spaces. Ensure this directory path exists on the host in question. Environment discovery will fail if the directory does not exist on the host.
  7. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
  8. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**. For more information, see [Providing Your Own Oracle Java](#)
  9. Click **Submit**. On success, the new environment will be added to the list in the Environments tab.
  10. Select the "Databases" tab to view discovered HANA databases:

Post-requisites

To view information about an environment after you have created it:

1. Click **Manage**.
2. Select **Environments**.
3. Select the **environment name**.

## Editing SAP HANA environment details

This topic describes how to edit the details of an environment. Once an environment has been added it is possible to change any of the following values:

- Environment OS user
- Host IP Address/Name
- SSH port
- Path to plugin location

### Procedure

1. Login to the **Delphix Management** application with admin credentials or as the owner of an environment.
2. Click **Manage**.
3. Select **Environments**.
4. In the **Environments** panel, click the name of an environment to view its details.
5. Next to **Environment Detail**, click the **Pencil** icon to edit.
6. Click the **Check** icon to save your edits.

## Changing the hostname or IP address for SAP HANA staging and target environments

Below is the procedure to change the Host Address of the HANA Staging and Target Environments (If the Host address of the underlying staging and target server has also changed):

### Procedure

1. Disable the dSources.
2. Disable the VDBs.
3. Login to the Delphix Management application.
4. Click **Manage**.
5. Select **Environments**.
6. Click on the existing environment name you want to modify and open the environment information screen.
7. In the Attributes section, click the **Pencil** icon located Next to it.
8. Update the Host address to the new one and save the results by clicking on .
9. The New Host address will now be updated.
10. Re-enable the dSources.
11. Re-enable the VDBs.

## Steps to modify SAP HANA dSource properties

Select the dSource and then the dSource **Configuration** tab to modify dSource properties. For example, to change the **Source SystemDB Username** or **Password**, select the **Dataset, Configuration,** and then the **Custom** tab as shown below:

The screenshot displays the 'DELPHIX MANAGEMENT' interface. The top navigation bar includes 'Manage', 'Resources', 'System', and 'Help'. On the left, a 'Datasets' sidebar shows a tree view with 'DSOURCE' expanded, containing 'DSOURCE\_1' (Active) and 'VDB'. The main content area is titled 'DSOURCE\_1' and features tabs for 'Timeflow', 'Status', and 'Configuration'. Under the 'Configuration' tab, there are sub-tabs for 'Source', 'Policies', 'Masking', 'Hooks', and 'Custom'. The 'Custom' sub-tab is active, showing the following configuration parameters:

- NFS Mount Location**: /mnt/provision/DSOURCE\_1
- SAP HANA Staging Tenant Database Name**: DSOURCE\_1
- Staging Database Parameters**
  - Staging SystemDB User Name**: SYSTEM
  - Staging SystemDB Password**: \*\*\*\*\*
  - Staging Tenant Database ADMIN User Name**: SYSTEM
  - Staging Tenant Database ADMIN Password**: \*\*\*\*\*
- Customer Provided Data Backup Location**: /hana/shared/HDB/CustomerBackup/BACKUP
- Customer Provided Log Backup Location**: Unset

## SAP HANA dSource ingestion

This release of the HANA 2.0 plugin uses Native Backups/Third-party backups to stage a dSource.

An External Backup is a form of HANA Native Backup that was created by users outside of Delphix. The necessary backup files must exist prior to the dSource operation and must be prepared by the user prior to ingestion by Delphix. In particular, a Delphix-supplied script must be run to persist vital backup metadata to Delphix during the dSource creation process. The backup files must be created on the source HANA instance must be made visible to the Staging host where the dSource is being created (ex: via shared storage, scp, etc).

A new data ingestion mechanism, Staging Push has been introduced that will help users to push data into the Delphix provided mount point on their own.

There are two mechanisms to create dSource on the staging server.

- Pull architecture, where the HANA plugin pulls the data into the Delphix provided mount location.
- Staging Push architecture, where the user pushes the data into the Delphix provided mount point on their own.

## Linking SAP HANA data sources

This topic describes basic concepts behind the creation of a dSource for a HANA database using conventional pull and Staging push mechanisms.

**⚠️ For Staging Push, only native/third-party backups are used to populate data in the staging database.**

For Third-party Backups, users need to provide a “Backup Path” containing FULL and Incremental backups. These files will be copied to the Delphix Engine during the dSource linking process. In this scenario, the Delphix Engine will not require any credentials of the source database. Although credentials for the tenant database (for which backup has been placed) and system database of staging instances would be required.

### Prerequisites for customer provided backups ingestion mechanism

- Users need to run the `create_backup_metadata.sh`. This script will create the `backupTimeInfo` file at the same location where backups are kept. This script will gather all the required metadata information and will store that information in the `backupTimeInfo` file. This information will then get used by the plugin at the time of creating dSource.
- More details regarding the script have been included in the [HANA 2.0 Plugin Tools](#)

### Procedure

1. Login to the Delphix Management application.
2. Select **Manage > Environments**. Then select the Datasets tab.

The screenshot displays the Delphix Management application interface. On the left, the 'Environments' sidebar shows a list with 'rhelsp5StgPerformance' selected. The main area is divided into 'Details' and 'Databases' tabs, with 'Databases' active. Under 'Installations', a specific HANA installation is listed with its path. A red arrow points to a '+' icon in the top right of the installation details, which is used to add a new source configuration.

3. Create a source configuration on which to build the dSource. You can do this by clicking on the + symbol. The Source configuration can have any name.
4. In the **Add dSource** wizard, select the required source configuration.
5. After selecting the source, below are the parameters required to create the dSource.
  - a. Parameters required for the conventional **pull** mechanism:
    - i. Mount Location on Staging Host
    - ii. SAP HANA Source Tenant Database Name
    - iii. Source SystemDB User Name
    - iv. Source SystemDB Password
    - v. Customer Provided Data Backup Location: This represents the path to the location of the customer-provided backup files.
    - vi. Customer Provided Log Backup Location: This represents the path to log the location of the customer-provided log backup files. This parameter is optional.

- b. Parameters required for the **Staging push** mechanism
  - i. Mount Location on Staging Host
  - ii. SAP HANA Source Tenant Database Name
  - iii. Enable the **Staging Push** feature by selecting the checkbox "**Use Staging Push**". With this feature, the user handles the Source Tenant database and its state on their own and you don't need to specify any other staging database parameters, data backup, and log backup locations. If this check box is selected, the HANA plugin will not invoke the tenant creation and recovery operation and if this checkbox is not selected then the default pull approach will be used.

- c. Click **Next**.
- 6. Enter a name and select a group for your dSource. Adding a dSource to a dataset group lets you set Delphix Domain user permissions for that database and its objects, such as snapshots. See the topics under [Users and Groups](#) for more information.
- 7. Configure the **SnapSync** and **Retention Policy**. The SnapSync policy can be set to 'None' for customers who wish not to run a scheduled SnapSync job.
- 8. Optionally, users can provide the bash script as a plugin-defined hook. Both Pre-SnapShot and Post-SnapShot hooks can be used.
- 9. Select **Next**.
- 10. At the end of the workflow, review the **dSource Configuration** in the **Summary** pane as shown below:

Add dSource
✕

Once the dSource linking job is submitted it is possible to monitor progress by selecting **Active Jobs** in the top menu bar. On successful completion, the new dSource will be visible in the list of Datasets under its assigned group.

After dSource creation using the Staging Push mechanism, an empty snapshot will be created but users can not create VDB's from the same. Also, before creating the subsequent snapshots, users will have to create the database and point the database to use the Delphix provided mount point.

## Staging push implementation details

This topic provides implementation details of the Staging Push for the HANA plugin. Staging Push will help users to push data into the Delphix provided mount point on their own.

Staging Push gives users control over some Staging DB processes. It will give control of the staging database to the user to pull from any backup provider. Staging database files will be stored on Delphix Storage. Delphix will still be the one snapshotting the underlying data files, and gathering the metadata required to provision from the snapshot.

The below steps show how to create a dSource using the Staging Push mechanism.

### dSource creation

The first snapshot created as a part of dSource creation contains data and log directories within the Delphix created mount point. These directories are empty for the first snapshot.

The following snippet shows how the file system appears inside the Delphix created mount point.

```
[hdbadm@target:/delphix/zfs> tree
```

```

.
├── data
└── log

```

```
2 directories, 0 files
```

```
[hdbadm@target:/delphix/zfs> pwd
/delphix/zfs
```

 If a system user attempts to create a VDB from this snapshot, it will fail with the below error message.

Provision virtual database "N5RQVO".

#### Error

Data volumes are not found under the data directory. Please check that the dSource snapshot contains the valid data and log volumes required for VDB creation.

#### Error Code

exception.plugin.user.error.detected

#### Suggested Action

Please take a new snapshot of the dSource with valid data and log volumes and try again.

### Subsequent Snapshots

The system user needs to follow the steps and commands below before taking any subsequent snapshots.

The system user needs to provide the values for all the parameters provided within {}.

1. Create a database in "no start" mode. Here, "no start" implies that the database is not started.  
create database {DATABASE\_NAME} SYSTEM USER {DATABASE\_PASSWORD} no start.

The parameters used in the below example are:

- a. DATABASE\_NAME - Refers to the database name to be used for staging Push. This is the same name that was provided by the system user on the UI while creating the dSource.
- b. DATABASE\_PASSWORD - Refers to the password to be used for the staged database. Example:

2. Set the HANA database to use the Delphix created mount point to store the data and log volume files. This is done by setting the `basepath_datavolumes` and `basepath_logvolumes` to `data` and `logdirectory` under the mount point, respectively. All the tenant data volumes and log volumes reside in the single mount point provided by Delphix.

```
//This query sets the value of basepath_datavolumes to within the delphix storage.  
alter system alter configuration('global.ini', 'DATABASE', '{DATABASE_NAME}')  
SET ('persistence', 'basepath_datavolumes') = '{DELPHIX_MOUNT_LOCATION}/data'
```

```
//This query sets the value of basepath_logvolumes to within the delphix storage.  
alter system alter configuration('global.ini', 'DATABASE','{DATABASE_NAME}')  
SET ('persistence','basepath_logvolumes') = '{DELPHIX_MOUNT_LOCATION}/log'
```

Example:

Once the `basepath_datavolumes` and `basepath_logvolumes` parameters are set for the tenant, then their values are reflected in the `global.ini` file in the tenant database. The location of the `global.ini` file is `<sapmnt>/<SID>/SYS/global/hdb/custom/config/DB_<tenantdbname>`. Example:

3. Create a backup catalog. This is used by HANA to determine whether recovery is possible and which backups are to be used to recover the database.

Creating a backup catalog is not applicable for third-party backups. For example, Commvault-based backups.

The parameters used in the below example are:

- a. logDirs - Refers to the location where logs are present for the database. If the system user does not intend to use logs then an empty directory can be created and the location of the empty directory can be provided here.
- b. dataDir - Refers to the location where backups are present.
- c. -d - Refers to the location where the catalog backup will be created.

Example:

4. Perform recovery on the tenant database. This can be done in the following two ways:

a. Recovery using data backups only The following parameters for the recovery command are listed below:

- i. Recover database for {DATABASE\_NAME} - Represents the name of the database for which recovery is to be performed.
- ii. Until timestamp '{TIMESTAMP}' - Represents the timestamp value till which recovery is to be performed.
- iii. Clear log using catalog path ('{CATALOG\_PATH}') - Refers to the path where the catalog backups are kept.
- iv. Using data path ('{DATA PATH}') - Refers to the path where the data backups are kept.

Example:

Recovery using both data and log backup Along with the above parameters, you need to specify the below parameter:

- v. Using log path ('{LOCATION\_OF\_THE\_LOG\_PATH}') - Refers to the location of log backups.
- b. Recovery using third-party data backups. For example, Commvault-based backups. The following parameters for the recovery command are listed below:
  - i. STAGING\_DATABASE\_NAME - Represents the name of the tenant database to be created on the staging area.
  - ii. RECOVERY\_TIMESTAMP - Represents the time limit until which recovery has to be performed. The time has to be in the YYYY-MM-DD HH:MM:SS format.
  - iii. SOURCE\_TENANT\_DATABASE - Represents the name of the source tenant database.
  - iv. SOURCE\_SID - Represents the SID of the source HANA installation. Example:

Once the recovery is done, data will be available inside the Delphix mount point and the database will be in an active state. The below snippet shows an example file system after the recovery.

You can now proceed to take a snapshot and the VDB creation using the new snapshot.

## Advanced data management settings for SAP HANA dSources

This topic describes advanced data management settings for dSources.

When linking a dSource, you can use custom data management settings to improve overall performance and match the needs of your specific server and data environment. If no specific settings are required, leverage default data management settings.

### Accessing data management settings

There are three ways to set or modify data management settings for dSources:

1. During the dSource linking process, in the Policies tab of the Add dSource wizard select the **Retention Policy**.
2. Or select **Manage**, then select **Policies**.
3. In the Policies screen select the **Retention** tab. To manage retention on target after the dSource snapshots have been deleted from the replication source, select the **Replica Retention** tab.
4. To add a new retention policy click the **+Retention** button, and to add a new replica retention policy on the replication target, click the **+Replica Retention** button.
5. This will open the Retention or the Replica Retention Policy wizard, depending upon the above selection. Enter a policy name along with required retention details and click **Submit**. For more information, see [Policies for Scheduled Jobs](#)

### Retention policies - retention/replica retention

Retention policies define the length of time Delphix Engine retains snapshots within its storage. To support longer retention times, you may need to allocate more storage to the Delphix Engine. The retention policy – in combination with the SnapSync policy – can have a significant impact on the performance and storage consumption of the Delphix Engine.

Replica Retention policies define how long the snapshots are retained on replicated namespaces for dSources and VDBs after they have been deleted on the replication source. Normally, the snapshots that have been deleted on the replication source engine are also deleted on the replication target engine. A new retention policy is introduced to provide an extended lifetime of such snapshots on the replication target.

### Benefits of longer retention

Increased retention times for snapshots extends the quantity of historical data the Delphix Engine will retain.

Common use cases for longer retention include:

- SOX compliance
- Frequent application changes and development
- Caution and controlled progression of data
- Reduction of project risk
- Restore to older snapshots

## Working with SAP HANA dSource snapshots

Taking a snapshot creates a new snapshot entry in the dSource's Timeflow.

### Snapshot (default)

This section lists the steps to take a snapshot and delete the same.

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the **Camera** icon. Alternatively, click the arrow next to the Camera icon and select **Snapshot (default)**.
5. From the Snapshot dialog, select **Perform Snapshot**.
6. Click **View:** under **Timeflow** to verify the Snapshot you just created.
7. To delete, select the snapshot you just created, and from the Actions menu (...) select **Delete Snapshot**.
8. In the Delete Snapshot dialog, select **Delete**.
9. Click **View:** under **Timeflow** to verify the Snapshot, you just deleted.

### Snapshot with parameters

This section lists the steps to take a snapshot with parameters and delete the same.

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the dSource you want to Snapshot.
4. Click the arrow next to the Camera icon and select **Snapshot with Params...**
5. Select **Refresh Prior to Snapshot** to refresh the staging database. This will refresh the staging database prior to taking the snapshot.

**Snapshot** ✕

---

Refresh Prior to Snapshot

Refresh the state of staging database prior to taking snapshot to change its data contents. Uncheck the box if you wish to snapshot the staging database in its current state.

---

Cancel Perform Snapshot

6. In the Snapshot dialog, select **Perform Snapshot**.
7. Click **View:** under **Timeflow** to verify the Snapshot you just created.
8. To delete, select the snapshot you just created, and from the Actions menu (...) select **Delete Snapshot**.
9. Click **View:** under **Timeflow** to verify the Snapshot, you just deleted.

## Source sizing implementation for SAP HANA data sources

The source sizing feature aligns the data source experience with Delphix database standards that will improve your ingestion reporting experience on the per TB pricing model. This feature enables you to calculate the dataset size based on the total allocated space on the mount point provided by the Delphix Engine for the dataset.

### Procedure

- For all datasets, the size of the dataset can be calculated using `du -sb <dataset>` command that provides the correct volume and apparent size of the datasets.
- Source sizing is implemented for below staging pull methods:
  - For the dSource created using external backup ingestion method
  - For the dSource created using staging push method

## Provisioning SAP HANA VDBs: an overview

This topic describes the basic concepts involved with provisioning of VDBs in HANA.

Provisioning of a VDB results in creation of a new tenant database in the specified HANA target environment, with storage for the new tenant backed by Delphix storage. The data inside the tenant reflects the same data in that exists in the dSource snapshot from which the VDB is being provisioned. During the provision process, Delphix will create a filesystem in Delphix specifically for the new VDB, populate the filesystem with the appropriate data files and datafile contents, then share and mount that filesystem onto the specified HANA target host. The new HANA tenant will have its storage paths re-configured to use a single subdirectory specific to the tenant, then traverse an NFS mount which points to the filesystem on Delphix for that tenant. The VDB provision operation is very fast because Delphix does not move nor copy data to create and populate the VDB filesystem.

During the VDB creation, the location of the basepath\_datavolumes and basepath\_logvolumes will be changed to use the storage inside the Delphix Engine. This will mean that any new services (even if a user creates a service post VDB creation by the plugin) which will now be created for the virtualized tenant will also be created on the tenant-specific filesystem on the Delphix Engine.

### Setting log mode overwrite

As a part of the VDB creation process, if the correct tenant username and password are provided, then the log mode for the virtualized tenant will be set to 'overwrite'. It means that "No log backups" are created. When savepoints are written, log segments are immediately freed to be overwritten by new log entries.

### HANA port control

Starting Delphix Engine 6.0.10.0 and HANA vSDK plugin, Delphix introduces a solution that keeps the port numbers consistent throughout the VDB life cycle so that the connections made to the VDBs are not disrupted during their life cycle.

### Need for user specified ports?

Until now, Delphix HANA was dependent on the HANA-provided ports for any VDB. Every VDB has its own ports and connections for internal and external communication. When operations such as rewind, refresh, or enable are performed on VDBs, this can cause port instability or inconsistency problems because the port numbers could change even when the VDB name remains the same. The below points further elaborates on this limitation.

- The plugin uses HANA-provided port numbers which are selected from the available pool of port numbers in the bottom-up approach that means an idle port number at the bottom will be picked first for use.
- The plugin does not have any mechanism to remember these port numbers and use them from the pool at the time of creating any tenant database again at the time of enabling, refresh, or rewind.  
So if we had a tenant TEST having a service indexserver at 30043 port number, then after the refresh, rewind or enable, there will be a chance that
  - a. The same port number(30043) is not available
  - b. Any port number lesser than the one being used earlier(30043) is now available.

So, there are chances that the tenant TEST is provided with another port number for the same service by HANA and if there was any connection made to the tenant TEST at 30043 will now be disrupted. Hence there is a need for a solution that allows the database to keep the port number consistent throughout the VDB life cycle.

### How does the HANA port allocation works?

The port control feature now provides an option to specify port numbers at the time of VDB creation. This can be done in the following two ways.

#### User-specified HANA ports

See the procedure for [Provisioning HANA VDBs](#) where the user can specify the HANA service and port number at the time of VDB creation.

By Plugin itself

If the service and port numbers are not provided by the user on the Plugin user interface, then the plugin itself will decide the port number and will keep the ports consistent throughout the life of a VDB.

This is how the plugin chooses the ports:

- It is based on the value of the `reserved_instance_number` parameter in the `global.ini` file. This file is located at `/hana/shared/{DATABASE_SID}/global/hdb/custom/config`. If this parameter is not defined in `global.ini`, then the value of the instance number will be used.
- Ports will be decided by the HANA plugin in a top-down manner which means that the topmost port which is free will be used first and so on.

## Provisioning SAP HANA VDBs

This topic describes how to provision a virtual database (VDB) from a HANA dSource.

### Prerequisites

- The provision requires a linked dSource built off a physical source tenant, as described in [Linking a HANA dSource](#), or a VDB.
- The HANA target environment should adhere to the [Requirements for HANA Hosts and Databases](#)
- Operating system users and database users should be configured.

### VDB creation UI

The screenshot shows the 'Provision VDB' wizard in the 'Target Configuration' step. The left sidebar contains a navigation menu with options: Preparation, Source, Provision Point, Target Environment, Target Configuration (selected), Configuration, Policies, Masking, Hooks, and Summary. The main area is titled 'Target Configuration' and includes the following fields and sections:

- NFS Mount Location \***: A text input field with a tooltip: 'Mount location on target host.'
- SAP HANA Target Tenant Database Name \***: A text input field with a tooltip: 'The name of the Virtual (Remote) Database to be created.'
- Target SystemDB User Name \***: A text input field.
- Target SystemDB Password \***: A text input field with a tooltip: 'Double quote, single quote or space characters are not valid.'
- Configure Tenants Service and Port**: A section containing a table of tenants:
 

Tenant Database Level information	
Tenant service and port number indexserver:30040	Delete
Tenant service and port information separated by a ":". For example: service_name:port	
Tenant service and port number xsengine:30043	Delete
Tenant service and port information separated by a ":". For example: service_name:port	
- + Add**: A button to add new tenants.

At the bottom right of the wizard, there are four buttons: 'Cancel', 'Back', 'Next', and 'Submit'.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select a **dSource**.
5. Select a **snapshot** from which you want to provision.
 

**Note:**  
If the first or empty dSource Snapshot that was created using the Staging Push mechanism is detected by the plugin and an error message is displayed. This check is done for every VDB creation operation.
6. Click the **Provision VDB** icon to open the Provision VDB wizard.
7. Select a target environment from the left pane.
8. The HANA 2.0 Plugin supports one installation on the same host, hence the value in the **Installation** dropdown will be already populated. Multiple drop-down options should not be available.
9. Set the **Environment User** to be the Instance Owner. Note: The picking of instance owner is only possible if you have multiple environment users set on that host.
10. Click **Next**.
11. In the **Target Configuration** pane you will need to specify the following:
 

Info : **\*!** indicates the mandatory fields.

- a. NFS Mount Location \*: Delphix recommends setting the trailing directory to match the VDB name to delineate mount points and support administration and troubleshooting. In the example shown, the **NFS Mount Location** is /mnt/provision/dev where dev matches the **SAP HANA Target Tenant Database Name**.
- b. SAP HANA Target Tenant Database Name \*: This refers to the target tenant database name which will be created upon VDB creation.
- c. **Target SystemDB User Name** \*: This refers to the SystemDB username in the target database.
- d. **Target SystemDB Password** \*: This refers to the SystemDB password in the target database.

**Note:**

The SYSTEM username and password derived from the physical source database should be entered during the provision of a VDB because those credentials will be recovered during provisioning.

- e. Configure Tenants Service and Port: This refers to the list of tenant services and port numbers in the following format.

```
<service>:<port>For example, indexserver:30043
```

You can click "+Add" to add more services.

Info :

- This is not a mandatory field. If a user doesn't provide a value to this, then the plugin will proceed with the above fields and it will allocate the service and port on its own.
- If an invalid service is provided, the plugin will proceed with input, but will eventually fail while creating the service and will display an error on the Delphix Engine UI.

## 12. In the configuration section

- a. Set the vFile Name or accept the default, which is a random string. Delphix strongly recommends applying a consistent naming convention. We suggest this name should match the Target Tenant Name from the previous pane. Maintaining a consistent naming convention will support administration and troubleshooting activities. In the example shown, the vFile Name “dev” matches the actual tenant name and mount point from the previous pane.
- b. Select a **Target Group** for the VDB. Click the **Add Dataset Group** icon to add a new group if required.
- c. Set **Auto VDB Restart** option to automatically restart the VDB, where the target host is rebooted. Delphix recommends enabling this setting.

13. Click **Next**.

14. VDB **Snapshot Policy**. Select the Snapshot policy if an automated VDB snapshot schedule is required. Optionally, the Snapshot policy may be disabled by selecting “None”.

15. Click **Next**.

16. **Masking**. This page offers the opportunity to link the provision job to a masking job. At this time, Delphix Masking does not support HANA. Please do not use this option. “Mask this VDB” should remain deselected.

17. **Hooks**. Run a customized shell script via a hook operation at a particular moment in the provision operation.

18. Click **Next**.

19. **Summary**. Presents an opportunity to review all the information as a part of the initial provision workflow.

20. Click **Submit**. Once a provision job is submitted it is possible to monitor its progress by selecting “Active Jobs” in the top menu bar. On successful completion, VDB will be visible in the list of Datasets under its assigned group.

## Working with SAP HANA VDB snapshots

Taking a snapshot creates a new snapshot entry in the VDB's Timeflow.

This section lists the steps to take a snapshot and delete the same.

1. Login to the **Delphix Management** application.
2. Click **Manage** and select **Datasets** from the dropdown list.
3. Select the VDB you want to perform Snapshot.
4. Click the **Camera** icon.
5. From the Snapshot dialog, select **Yes**.
6. Click **View:** under **Timeflow** to verify the Snapshot you just created.
7. To delete, select the snapshot you just created, and from the Actions menu (...) select **Delete Snapshot**.
8. In the Delete Snapshot dialog, select **Delete**.
9. Click **View:** under **Timeflow** to verify the Snapshot, you just deleted.

## Failure during provision

Depending on where in the provision process failure occurs, and the type of failure, extra steps may be required:

- **Force Delete** of the provision object using the User Interface - The **Force Delete** option will remove underlying filesystems shared from the Delphix Engine, irrespective of any perceived dependencies on these filesystems. If provisioning fails very early in the process, it is common for the **Force Delete** option to be the only way to remove an object. This may happen when for example, the wrong password has been entered for the target-side system database user:

- In rare cases, removal of a failed virtual tenant may be required. For example a tenant with the name “TST”.

```
SELECT * FROM M_DATABASES WHERE DATABASE_NAME='TST';
ALTER SYSTEM STOP DATABASE TST IMMEDIATE;
DROP DATABASE TST DROP BACKUPS;
```

- If the **Force Delete** option could not unmount the virtual tenant mount points, then the unmount command should be run to remove the stale mount points.

```
umount -lf /mnt/provision/example
```

## SAP HANA hook operations

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at /bin/sh. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Admin application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi
exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a bash binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Admin application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

#### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi
exit 0
```

## Shell operation tips

### Using nohup

You can use the nohup command and process backgrounding from the resource in order to "detach" a process from the Delphix Engine. However, if you use nohup and process backgrounding, you MUST redirect stdout and stderr.

Unless you explicitly tell the shell to redirect stdout and stderr in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either stdout or stderr.

Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your RunCommand operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad examples

- nohup python file.py & # no redirection
- nohup python file.py 2>&1 & # stdout is not redirected
- nohup python file.py 1>/dev/null & # stderr is not redirected
- nohup python file.py 2>/dev/null & # stdout is not redirected

#### Good examples

- nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs that normally can only be used interactively, such as ssh. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Admin application and CLI to aid in debugging.

If successful, the script must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

#### Example of a RunExpect operation

Start an ssh session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
    -re {Password: } {
        send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
    }
    timeout {
```

```

        puts "Timed out waiting for password prompt."

        exit 1
    }
}
exit 0

```

### HANA environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set certain environment variables so that the user-provided script can use them to access the dSource or VDB.

### dSource environment variables

Environment Variable	Description
DLPX_DATA_DIRECTOR	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to link the dSource

### VDB environment variables

Environment Variable	Description
DLPX_DATA_DIRECTOR	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to provision the VDB

### Shell operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at /bin/sh. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Admin application and command-line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi
exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE" "second argument in double quotes" 'third argument in single quotes'
```

### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a bash binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Admin application and command-line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi
exit 0
```

### Shell operation tips

#### Using nohup

You can use the nohup command and process backgrounding from the resource in order to "detach" a process from the Delphix Engine. However, if you use nohup and process backgrounding, you MUST redirect stdout and stderr.

Unless you explicitly tell the shell to redirect stdout and stderr in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either stdout or stderr.

Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your RunCommand operation background a long-running Python process. Below are the bad and good ways to do this.

#### **Bad examples**

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

### Good examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs that normally can only be used interactively, such as ssh. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Admin application and CLI to aid in debugging.

If successful, the script must exit with an exit code of 0. All other exit codes will be treated as an operation failure.

### Example of a RunExpect operation

Start an ssh session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
    -re {Password: } {
        send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
    }
    timeout {
        puts "Timed out waiting for password prompt."
        exit 1
    }
}
exit 0
```

### HANA environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set certain environment variables so that the user-provided script can use them to access the dSource or VDB.

## dSource environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to link the dSource

## VDB environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	The primary mount path provided by the user on the UI. The first one, in case multiple mount specifications are provided.
USER	The OS user used to provision the VDB

## SAP HANA overview

SAP HANA is an in-memory database, columnar-oriented database management system developed by SAP. The key differentiators of HANA are its tight integration into the SAP application stack coupled with its columnar store, the latter of which is intended to enable customers to fold both OLTP and OLAP operations into a single database entity. In practical terms, this means an SAP HANA database stores both analytical and transactional data. Analysis of the data combination is possible on the fly, helping businesses make real-time analytical decisions.

SAP HANA as a database product continues to evolve dramatically. Key among recent changes has been the movement from a Single Database Container (SDC) to Multi-Tenant Database Containers (MDC), an architectural change that has become the exclusive architecture of HANA version 2.0.

## Implications of the HANA column store

In a row-based relational database, data is stored by row, usually in large files. Data is then accessed from the database by reading and returning full rows of data.

### Row

```
Country Product Sales
1  US Alpha  3000
2  US Beta   1250 <-----storing this line across----->
3  JP Alpha   400
4  UK Alpha   700
```

### Column

```
Country Product Sales  ^
US      Alpha 3000      |
US      Beta 1250      storing each column up / down
JP      Alpha 400       |
UK      Alpha 700       v
```

## Select

In a columnar database, the entire row does not need to be read, only the columns associated with the query. This columnar structure improves (read) efficiency and, therefore, query performance, particularly for extensive data sets.

Columnar data storage allows highly efficient compression because most of the columns contain only a few distinct values (compared to the number of rows). The data, therefore, has a smaller memory footprint and takes fewer processing cycles to interrogate.

Better parallel Processing: in a column store, data is already vertically partitioned. This means that operations on different columns can easily be processed in parallel. If multiple columns need to be searched or aggregated, each of these operations can be assigned to a different processor core.

## Insert / Update

Storing data in columns instead of rows is challenging for workloads with many data modifying operations. Therefore, the concept of a differential buffer was introduced, where new entries are written to a differential buffer

first. In SAP HANA, this is referred to as the delta store. In contrast to the main store, the delta store is optimized for inserts. At a later point in time and depending on thresholds, e.g. the frequency of changes and new entries, the data in the delta store is merged into the main store. This process is referred to as delta merge.

The delta merge process has important implications for filesystem-based table modifications. Delta merge on any table will reorganize all data in that table and as a corollary will re-write the entire table to different filesystem blocks. *The space savings Delphix can offer by tracking block changes between snapshots becomes far less effective or predictable when entire tables are reorganized as a function of delta merge.*

## Unstructured files and app data

This section contains the following topics:

- [Getting started with unstructured files](#)
- [Unstructured files environment requirements](#)
- [Create an empty VDB for unstructured files in the Delphix Engine](#)
- [Provisioning unstructured files as vFiles](#)
- [Managing vFiles](#)
- [vFiles best practices and common pitfalls](#)
- [Delphix Engine plugin management](#)
- [Unstructured files hook operation notes](#)

## Getting started with unstructured files

The term “unstructured files” refers to data stored in a filesystem that is NOT usually accessed by a DBMS or similar software. Unstructured files can consist of anything from a simple directory to the root of a complex application like Oracle Enterprise Business Suite. Like with other data types, you can configure a dSource to sync periodically with a set of unstructured files external to the Delphix Engine. The dSource is a copy of these physical files stored on the Delphix Engine. On Unix platforms, dSources are created and periodically synced by an implementation of the rsync utility. On Windows, files are synced using the robocopy utility, which is distributed with Windows. dSources enable you to provision “vFiles,” which are virtual copies of data that are fully functional read-write copies of the source of the original file. You can mount vFiles across one target environment or many.

## Unstructured files environment requirements

This section contains the following topics:

- [Unstructured files on unix environments](#)
- [Unstructured files on windows environments](#)
- [Linking unstructured files](#)

## Unstructured files on unix environments

This section contains the following topics:

- [Requirements for Unix environments](#)
- [Network and connectivity requirements for Unix environments](#)
- [Sudo privilege requirements for unstructured files on Unix](#)
- [Sudo file configuration examples for unstructured files on Unix](#)
- [Adding a Unix environment](#)

## Requirements for Unix environments

This topic outlines the supported operating systems (OSs) for use on UNIX source and target environments.

### Supported operating systems

Operating System	Version	Processor Family
Solaris	10, 11	SPARC x86_64
Red Hat Enterprise Linux	5.5 - 5.11 6.1 - 6.10 7.0 - 7.8 8.0	x86_64
Oracle Enterprise Linux	5.5 - 5.11 6.1 - 6.10 7.0 - 7.8 8.0	x86_64
SUSE Linux Enterprise Server	11, 11SP1	x86_64
AIX	6.1, 7.1, 7.2	Power
HP-UX	11i v3 (11.31)	IA64
Ubuntu	18, 20	X86_64

Delphix supports all 64-bit OS environments for source and target.

 PHNE\_37851 - resolves a known bug in HP-UX NFS client prior to HP-UX 11.31.

### Additional source environment requirements

- There must be an operating system user with these privileges. For example, here in this section `delphix_os` is the primary user for the environment:
  - Ability to login to the source environment via SSH
- There must be a directory on the source environment where you can install the Delphix platform Toolkit – for example, `/var/opt/delphix/toolkit`.
  - The **delphix\_os** user must own the directory
  - The directory must have permissions `-rwxrwx---` (0770), but you can also use more permissive settings
  - The **delphix\_os** user must have read and execute permissions on each directory in the path leading to the toolkit directory. For example, when the toolkit is stored in `/var/opt/delphix/toolkit`,

- the permissions on `/var` , `/var/opt` , and `/var/opt/delphix` should allow read and execute for "others," such as `-rwxr-xr-x`.
- The directory should have 1.5GB of available storage: 400MB for the toolkit and 400MB for the set of logs generated by each client that runs out of the toolkit
- On a Solaris host, `gtar` must be installed. Delphix uses `gtar` to handle long file names when extracting the toolkit files into the toolkit directory on a Solaris host. The `gtar` binary should be installed in one of the following directories:
  - `/bin:/usr`
  - `/bin:/sbin:/usr`
  - `/sbin:/usr/contrib`
  - `/bin:/usr/sf`
  - `/bin:/opt/sfw`
  - `/bin:/opt/csw/bin`
- The Delphix Engine must be able to initiate an SSH connection to the source environment

#### Additional target environment requirements

- There must be an operating system user with these privileges. Here we use `delphix_os` as an example for the primary user for the environment:
  - Ability to login to the target environment via SSH
  - The following permissions are usually granted via sudo authorization of commands.
  - See [Sudo Privilege Requirements](#) for further explanation of the commands and [Sudo File Configuration Examples for Unstructured Files on Unix](#) for examples of the `/etc/sudoers` file on different operating systems.
    - The primary user for the target environment must have the ability to run `mount`, `umount`, `mkdir`, and `rmdir` as a super-user on any directory mounted to by the Delphix Engine.
    - If the target host is an AIX system, permission to run the `nfsd` command as a super-user
- There must be a directory on the target environment where you can install the Delphix Engine Toolkit - for example, `/var/opt/delphix/toolkit`.
  - The **delphix\_os** user must own the directory
  - The directory must have permissions `-rwxrwx---` (0770), but you can also use more permissive settings
  - The **delphix\_os** user must have read and execute permissions on each directory in the path leading to the toolkit directory. For example, when the toolkit is stored in `/var/opt/delphix/toolkit` , the permissions on `/var` , `/var/opt` , and `/var/opt/delphix` should allow read and execute for "others," such as `-rwxr-xr-x`.
  - The directory should have a total of at least 800MB of storage, plus 1MB of storage per vFile that will be provisioned to the target
- On a Solaris host, `gtar` must be installed. Delphix uses `gtar` to handle long file names when extracting the toolkit files into the toolkit directory on a Solaris host. The `gtar` binary should be installed in one of the following directories:
  - `/bin:/usr`
  - `/bin:/sbin:/usr`
  - `/sbin:/usr/contrib`
  - `/bin:/usr/sf`
  - `/bin:/opt/sfw`

- `/bin:/opt/csw/bin`
- There must be a directory under which the mount points are created when provisioning a vFile to the target environment. The group associated with the directory must be the primary group of the delphix-os user. Group permissions for the directory should allow read, write, and execute by members of the group.
- The Delphix Engine must be able to initiate an SSH connection to the target environment.
- NFS client services must be running on the target environment.
  - Required packages on target hosts:
    - i. Portmapper (rpcbind)
    - ii. status daemon (rpc.statd)
    - iii. NFS lock manager (rpc.lockd/lockmgr)
  - The Delphix Engine enables the use of NFSv3 by default for mounting target host filesystems, thus, the prerequisite packages to support NFSv3 client communication are required for normal operation. In addition, the required services to support NFS client communications (including file locking) must be running. These services are shown in the left column.
    - To enable NFSv4, which does not need to interact with those discrete services, See [NFSv4 configuration](#).

## Network and connectivity requirements for Unix environments

## Port allocations specific to unstructured files

The Delphix Engine makes use of the following network ports for unstructured files dSources and vFiles:

## Inbound to the Delphix Engine port allocation

Protocol	Port Number	Use
TCP	873	Rsync connections used for communication to <code>rsyncd</code> during SnapSync
TCP/UDP	111	Remote Procedure Call (RPC) port mapper used for NFSv3 mounts Note: RPC calls in NFSv3 use additional fixed ports for supporting services (lockd, mountd and statd) seen below.
TCP	1110	NFS Server daemon status and NFS server daemon keep-alive (client info)
TCP	2049	NFS Server daemon from vFiles to the Delphix Engine
TCP	54043	NFSv3 mount daemon
TCP	54044	NFSv3 stat daemon (lock state notification service)
TCP	54045	NFSv3 lock daemon/manager
UDP	33434 - 33464	Traceroute from source and target database servers to the Delphix Engine (optional)

## Outbound from a source environment port allocation

Protocol	Port Numbers	Use
TCP	873	Rsync connections used during SnapSync
TCP	xxxx	DSP connections used for monitoring and script management during SnapSync. Typically DSP runs on port 8415.

## Inbound to a source environment port allocation

Protocol	Port Numbers	Use
TCP	22	SSH connections to the source environment

Outbound from a target environment port allocation

Protocol	Port Numbers	Use
TCP	873	Rsync connections used during V2P
TCP	xxxx	DSP connections used for monitoring and script management. Typically DSP runs on port 8415.

Inbound to a target environment port allocation

Protocol	Port Numbers	Use
TCP	22	SSH connections to the target environment

General outbound from the Delphix Engine port allocation

Protocol	Port Numbers	Use
TCP	25	Connection to a local SMTP server for sending email
TCP/UDP	53	Connections to local DNS servers
UDP	123	Connection to an NTP server
UDP	162	Sending SNMP TRAP messages to an SNMP Manager
TCP	443	HTTPS connections from the Delphix Engine to the Delphix Support upload server
TCP/UDP	636	Secure connections to an LDAP server
TCP	8415	Connections to a Delphix replication target. See <a href="#">Configuring Replication</a> .
TCP	50001	Connections to source and target environments for network performance tests.

## General inbound to the Delphix Engine port allocation

Protocol	Port Number	Use
TCP	22	SSH connections to the Delphix Engine
TCP	80	HTTP connections to the Delphix GUI
UDP	161	Messages from an SNMP Manager to the Delphix Engine
TCP	443	HTTPS connections to the Delphix Management Application
TCP	8415	Delphix Session Protocol connections from all DSP-based network services including Replication, SnapSync for Oracle, V2P, and the Delphix Connector.
TCP	50001	Connections from source and target environments for network performance tests via the Delphix CLI.

## Firewalls and Intrusion Detection Systems (IDS)

Production databases on source environments (for dSources) are often separated from the non-production environment by firewalls. Firewalls can add milliseconds to the latency between servers. Accordingly, for best performance, there should be no firewalls between the Delphix Engine and the virtual database (VDB) target environments. If the Delphix Engine is separated from a source environment by a firewall, the firewall must be configured to permit network connections between the Delphix Engine and the source environments for the application protocols (ports) listed above.

Intrusion detection systems (IDSs) should also be made permissive to the Delphix Engine deployment. IDSs should be made aware of the anticipated high volumes of data transfer between dSources and the Delphix Engine.

## Sudo privilege requirements for unstructured files on Unix

This topic describes `sudo` file privilege configurations necessary for interacting with the Delphix Engine when virtualizing unstructured files on Unix Environments.

## Sudo privilege rationale

Privilege	Sources	Targets	Rationale
<code>mkdir/rmdir</code>	Not Required	Optional	Delphix dynamically makes and removes directories under the provisioning directory during vFiles operations. This privilege is optional, provided the provisioning directory permissions allow the <b>delphix_os</b> user to make and remove directories.
<code>mount/umount</code>	Not Required	<b>Required</b>	Delphix dynamically mounts and unmounts directories under the provisioning directory during vFiles operations. This privilege is required because <code>mount</code> and <code>umount</code> are typically reserved for a super-user.
<code>nfso</code> (AIX only)	Not Required	<b>Required</b>	Delphix monitors NFS read and write sizes on an AIX target host. It uses the <code>nfso</code> command to query the sizes in order to optimize NFS performance for vFiles running on the target host. Only a super-user can issue the <code>nfso</code> command.

## Sudo file configuration examples for unstructured files on Unix

This topic describes `sudo` file privilege configurations necessary for interacting with the Delphix Engine when virtualizing unstructured files on Unix Environments.

### **i** Considerations for sudo access and account locking

The Delphix Engine tests its ability to run the `mount` command using `sudo` on the target environment by issuing the `sudo mount` command with no arguments. Many of the examples shown in this topic do not allow that. This causes a warning during environment discovery and monitoring but otherwise does not cause a problem. If your vFiles operations succeed, it is safe to ignore this warning.

However, some users configure the security on the target environments to monitor `sudo` failures and lockout the offending account after some threshold. In those situations, the failure of the `sudo` commands might cause the **delphix\_os** account to become locked. One workaround for this situation is to increase the threshold for locking out the user account. Another option is to modify `/etc/sudoers` to permit the **delphix\_os** user to run the `mount` command without parameters.

## Configuring `sudo` access on Solaris for unstructured files

On a Solaris SPARC target, `sudo` access to `mount`, `umount`, `mkdir`, and `rmdir` is required. In this customer example, super-user privileges are restricted to the virtual dataset mount directory `/delphix` and are further restricted to commands which mount data from a single Delphix Engine with IP address 100.245.235.12.

Delphix requires `umount -f` for emergency force unmounts on Solaris.

Additionally, `sudo` access to `ps` may be added to avoid warnings during discovery but is not required.

Example: Solaris `/etc/sudoers` entries for a Delphix Target for Unstructured Files

```
User_Alias DELPHIX_USER=delphix_os

Cmd_Alias DELPHIX_CMDS= \
/usr/sbin/mount 100.245.235.12\:*/delphix/*, \
/usr/sbin/mount * 100.245.235.12\:*/delphix/*, \
/usr/sbin/umount /delphix/*, \
/usr/sbin/umount * /delphix/*, \
/usr/sbin/umount -f /delphix/*, \
/usr/bin/mkdir /delphix/*, \
/usr/bin/mkdir -p /delphix/*, \
/usr/bin/rmdir /delphix/*
/usr/bin/ps
DELPHIX_USER ALL=(ALL) NOPASSWD: DELPHIX_CMDS
```

## Configuring `sudo` access on Linux for unstructured files

On a Linux target, `sudo` access to `mount`, `umount`, `mkdir`, and `rmdir` is required. In this customer example, super-user privilege is restricted to the virtual database mount directory `/delphix`. Aliases are used to restrict the Delphix Engines which are allowed to run these commands.

Delphix requires `umount -lf` for emergency force unmounts on Linux.

Example: Linux `/etc/sudoers` file for a Delphix Target for Unstructured Files

```
Defaults:delphix_os !requiretty

Cmd_Alias DELPHIX_ADMIN_CMDS= \
/bin/mount          /delphix/*, \
/bin/mount *        /delphix/*, \
/bin/umount         /delphix/*, \
/bin/umount *       /delphix/*, \
/bin/umount -lf     /delphix/*, \
/bin/mkdir -p -m 755 /delphix/*, \
/bin/mkdir -p       /delphix/*, \
/bin/mkdir          /delphix/*, \
/bin/rmdir          /delphix/*
/bin/ps
Host_Alias DELPHIX_HOSTS=delphix001, delphix002
delphix_os DELPHIX_HOSTS=NOPASSWD:DELPHIX_ADMIN_CMDS
```

Configuring `sudo` access on AIX for unstructured files

In addition to `sudo` access to the `mount`, `umount`, `mkdir`, and `rmdir` commands on AIX target hosts, Delphix also requires `sudo` access to `nfso`. This is required on target hosts for Delphix to monitor the NFS read/write sizes configured on the AIX system. The super-user access level is needed to run the `nfso` command. This example does not restrict the Delphix Engine which is allowed to run these commands.

Delphix requires `umount -f` for emergency force unmounts on AIX.

Example: AIX `/etc/sudoers` File for a Delphix Target for Unstructured Files

```
Defaults:delphix_os !requiretty
delphix_os ALL=NOPASSWD: \
/bin/mount, \
/bin/umount, \
/bin/mkdir, \
/bin/rmdir, \
/usr/sbin/nfso, \
/usr/bin/ps
```

Configuring `sudo` access on HP-UX for unstructured files

On the HP-UX target, as with other operating systems, `sudo` access to `mount`, `umount`, `mkdir`, and `rmdir` is required. This example does not restrict the Delphix Engine which are allowed to run these commands.

Example: HP-UX `/etc/sudoers` file for a Delphix Target for Unstructured Files

```
Defaults:delphix_os !requiretty
```

```
delphix_os ALL=NOPASSWD:/sbin/mount, /sbin/umount, /bin/mkdir, /bin/rmdir, /bin/ps
```

## Adding a Unix environment

This topic describes how to add a new Unix environment.

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Click the **Plus** icon next to **Environments**.
5. In the **Add Environment** dialog, select **Unix/Linux**.
6. Select **Standalone Host**.
7. Enter the **Host IP address**.
8. Enter an optional **Name** for the environment.
9. Enter the **SSH** port. The default value is **22**.
10. Enter a **Username** for the environment.
11. Select **Login Type**.
  - a. Password - enter the OS password associated with the user in Step 10, or
  - b. Public Key, or
  - c. Password Vault - select from an existing Enterprise Password Vault

**Note:**

**Using Public Key Authentication**

If you want to use public-key authentication for logging into your Unix-based environment, there are two options: use the engine's key pair or provide a key pair for this environment.

To use the engine's key pair:

- i. Select **Public Key** for the **Login Type**.
- ii. Click **View Public Key**.
- iii. Copy the public key that is displayed, and append it to the end of your `~/.ssh/authorized_keys` file. If this file does not exist, you will need to create it.
  1. Run `chmod 600 ~/.ssh/authorized_keys` to allow only the file's owner to read and write to it (make sure the file is owned by the user).
  2. Run `chmod 755 ~` to restrict access to the user's home directory so no other user may write to it.
  3. Run `chmod 700 ~/.ssh` so that others cannot write to it. The `~/.ssh` directory cannot be writable by group or other users. Otherwise, authentication will fail.

As an alternative, you can provide a key pair specific for this environment via the API or CLI.

12. For **Password Login**, click **Verify Credentials** to test the username and password.
13. Enter a **Toolkit Path**. The toolkit directory stores scripts used for Delphix Engine operations. It should have a persistent working directory rather than a temporary one.
14. Click **Submit**.

## Post-Requisites

After you create the environment, you can view information about it by doing the following:

1. Click **Manage**.
2. Select **Environments**.
3. Select the **environment name**.

## Unstructured files on windows environments

This section contains the following topics:

- [Requirements for Windows environments](#)
- [Windows iSCSI configuration requirements](#)
- [Network and connectivity requirements for Windows environment](#)
- [Adding a windows environment](#)
- [Options for linking unstructured files on Windows environments](#)

## Requirements for Windows environments

### Supported operating systems

- Windows Server 2012, 2012 R2
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

#### **Requires 64-Bit Windows**

Delphix must install the Delphix Connector on all Windows hosts that Delphix will directly communicate with. This means all target hosts, and source or staging hosts. The Delphix Connector only supports 64-bit versions of Windows.

See [Options for linking unstructured files on Windows environments](#) for more information about source vs. staging hosts.

### Additional source or staging environment requirements

- The Delphix Connector must be installed on the source or staging environment. You must have used the Delphix Connector to register this environment with the Delphix Engine.
- The `robocopy` utility must be installed on the source or staging Windows environment. `robocopy` is installed by default on Windows Server 2008, Windows Vista, Windows 7, and Windows 8. For other versions of Windows, it is available by downloading a resource kit from Microsoft.
- If using a staging environment, the source's files must be made available and readable to the environment user from the staging environment via a UNC path. For example, use Windows Sharing.

### Additional target environment requirements

- The Delphix Connector must be installed on the target environment. You must have used the Delphix Connector to register this environment with the Delphix Engine.

### Procedure for adding and installing the Delphix connector for Windows

All Windows environments that will communicate with Delphix must have the Delphix Connector installed. The instructions in this topic cover downloading Delphix Connector, running the Delphix Connector installer on the Windows machine, and then registering the environment with the Delphix Engine.

#### Procedure

##### Downloading the Delphix connector

-  Delphix Connector software supplied by Delphix Engine versions before 4.2.4.0 required that the Windows machine had SQL Server installed. If you are using a Windows machine that does not have SQL Server installed, you must download the Delphix Connector from a Delphix Engine of version 4.2.4.0 or higher.

The Delphix Connector can be downloaded through the Delphix Engine Interface, or by directly accessing its URL.

##### Using the Delphix Engine interface

 A Flash player must be available on the Windows host in order to download Delphix Connector using the Delphix GUI.

1. From the Windows machine that you want to use, start a browser session and connect to the **Delphix Management** application using the delphix\_admin login.
2. Click **Manage**.
3. Select **Environments**.
4. Next to **Environments**, click the **Plus** icon.
5. In the **Add Environment** dialog, select **Windows** in the operating system menu.
6. Select **Target**.
7. Select **Standalone**.
8. Click the download link for the **Delphix Connector Installer**. The Delphix Connector will download to your local machine.

#### Direct download

1. You can download the Delphix Connector directly by navigating to this URL: `http://<name of your Delphix Engine>/connector/DelphixConnectorInstaller.exe`

#### Installing Delphix connector

On the Windows machine that you want to want to use, run the Delphix Connector installer. Click **Next** to advance through each of the installation wizard screens.

 The installer will only run on 64-bit Windows systems. 32-bit systems are not supported.

1. For **Connector Configuration**, make sure there is no firewall in your environment blocking traffic to the port on the Windows environment that the Delphix Connector service will listen to.
2. For **Select Installation Folder**, either accept the default folder or click **Browse** to select another.
3. Click **Next** on the installer final **Confirm Installation** dialog to complete the installation process and then **Close** to exit the Delphix Connector Install Program.
4. Note: At this point, you can close the Delphix GUI dialog by clicking **Cancel**.

#### Registering environment with Delphix Engine

1. Return to the Delphix Management application.
2. Enter the **Environment Name**, **Host Address**, **Delphix Connector Port**, **OS Username**, and **OS Password** for the target environment.
3. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
4. In the Java Development Kit tab, enter the absolute path to your Oracle JDK and click **Next**.
5. Click **Submit**.

As the new environment is added, you will see two jobs running in the **Delphix Admin Job History**, one to **Create and Discover** an environment, and another to **create** an environment. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel.

#### Post-Requisites

- On the Windows machine, in the **Windows Start Menu**, go to **Services > Extended Services**, and make sure that the **Delphix Connector** service has a **Status** of **Started**, and that the **Startup Type** is **Automatic**.

### Windows iSCSI configuration requirements

Windows iSCSI configuration requirements are split into two types. These requirements are needed on both staging and target servers.

1. iSCSI configuration required for operational stability.
2. Optional iSCSI parameters for performance improvement.

 When target environments are discovered, Delphix will configure the Microsoft iSCSI Initiator Service for Automatic startup.

### iSCSI configuration required for operational stability

The following Microsoft iSCSI Initiator configuration parameters are required for the target and staging Hosts. For details about configuring registry settings, see [How to Modify the Windows Registry](#).

 You must reboot the Windows server after changing the iSCSI configuration parameters.

Registry Key	Registry Value	Type	Data
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\iSCSI\Discovery	MaxRequestHoldTime	REG_DWORD	0x384 (900)
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Disk	TimeOutValue	REG_DWORD	0x384 (900)
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Class\{4D36E97B-E325-11CE-BFC1-08002BE10318}\<Instance Number>\Parameters	MaxRequestHoldTime	REG_DWORD	0x12C (300)

These settings will improve operational stability for VDBs and staging databases. If these settings are not adjusted, SQL Server may raise errors if VDBs are accessed during a temporary infrastructure outage. Affected VDBs may need to be manually restarted using the Continuous Data Engine.

Delphix Knowledge Base article [KB1251](#) includes scripts to validate or set registry parameters so that they meet current Delphix recommendations.

### Optional iSCSI parameters for performance improvement

The following iSCSI Registry setting may improve SQL Server dSource and VDB performance on the staging and target hosts.

Registry Key	Registry Value	Type	Data
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces\ \<Interface GUID>	TcpAckFrequency	REG_DWORD	0x1 (1)

This setting is recommended for storage networks in Microsoft's TechNet article [iSCSI and the Nagle Algorithm](#), described in Microsoft's document [TcpAckFrequency to control the TCP ACK behavior](#).

In some environments, adjusting this setting may not improve performance compared to Windows defaults. Modifications to this registry parameter should be tested in each environment, to confirm that this provides a performance improvement.

#### Delphix Engine validation for Windows iSCSI configuration

Delphix Engine validates the Windows iSCSI Configurations that are set on any supported windows staging and target host with the Delphix recommended configurations while performing the following operations:

1. Add environment operation
2. Refresh environment operation
3. Enable environment operation

#### Prerequisites

1. Supported if you are using Powershell 3.0 or above - If you are on Powershell version below 3.0, then the job will be updated with a warning that the Powershell version on your host is not supported for validating iSCSI parameters.
2. The below alerts are applicable only for staging or target Windows hosts.

#### Additional Information

1. Delphix Engine will only validate and will not alter any configuration in the user environment.
2. On update of registry values on the target host to match Delphix recommendations, the faults from the Delphix engine will only be resolved if any of the operations (environment add, refresh or enable) is performed. Delphix engine will not monitor the state of the target host in the background and hence any change will not be picked up unless an operation is triggered. So, the user needs to take action for the change to reflect in faults.
3. On a successful Delphix Engine upgrade, the latest default iSCSI recommendations will be used for validations.

#### Troubleshooting

Type		Description
Fault(Severity = Warning)	ENVIRONMENT_ISCSI_CONFIG_MISMATCH	The single fault is thrown for all mismatched parameters
	ISCSI_FETCH_CONFIG_PARAM_FAILURE	The single fault is thrown for all parameters where we failed to fetch the value at the target host

Type		Description
Warning	ISCSI_CONFIG_PARAM_TIMEOUT	Job warning raised if we are unable to get the iSCSI parameters on the host within 5 minutes. No fault thrown at this point.
	ISCSI_PS_VERSION_NOT_SUPPORTED	Job warning raised if the PowerShell version is below 3 on the host side during the validation of the iSCSI parameters. No fault thrown at this point. The validation is skipped.
	ENVIRONMENT_ISCSI_CONFIG_MISMATCH	Job warning added for all mismatched parameters
	ISCSI_FETCH_CONFIG_PARAM_FAILURE	Job warning for all parameters where we failed to fetch the value at the target host

#### Identifying the instance number for iSCSI control class initiator drivers

1. From the Windows toolbar, click **Start** and select **Run** from the menu.
2. Type `regedit` in the **Open** field and click **OK**.
3. Go to the following registry key:  
HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Control\Class\{4D36E97B-E325-11CE-BFC1-08002BE10318}\<Instance Number> where the value of <Instance Number> is the one that shows a DriverDesc value of Microsoft iSCSI Initiator. Under the registry key, locate and expand the plus (+) sign next to the instance number. In the example below, the value of the instance number is 0002.

Name	Type	Data
(Default)	REG_SZ	(value not set)
DriverDate	REG_SZ	6-21-2006
DriverDateData	REG_BINARY	00 80 8c a3 c5 94 c6 01
DriverDesc	REG_SZ	Microsoft iSCSI Initiator
DriverVersion	REG_SZ	6.2.9200.16384
EnumPropPages32	REG_SZ	iscsi.sys,iscsiPropPageProvider
InfPath	REG_SZ	iscsi.inf
InfSection	REG_SZ	iscsiPort_Install_Control
MatchingDeviceId	REG_SZ	root\iscsiport
ProviderName	REG_SZ	Microsoft

Value of Instance Number

## Network and connectivity requirements for Windows environment

## Port allocations specific to unstructured files

The Delphix Engine makes use of the following network ports for unstructured files dSources and VDBs:

## Outbound from the Delphix Engine

Protocol	Port Numbers	Use
TCP	xxxx	Delphix Connector connections to source and target environments. Typically, the Delphix Connector runs on port 9100.

## Inbound to the Delphix Engine

Protocol	Port Number	Use
TCP	3260	iSCSI target daemon for connections from iSCSI initiators on the target environments to the Delphix Engine

## Outbound from a source, staging, or target environment

Protocol	Port Numbers	Use
TCP	80	The Delphix Connector registers environments over HTTP
TCP	xxxx	DSP connections used for monitoring and script management. Typically, DSP runs on port 8415.

## Inbound to a source, staging, or target environment

Protocol	Port Numbers	Use
TCP	xxxx	Delphix Connector connections to source environments. Typically, the Delphix Connector runs on port 9100.
TCP	445	If a staging environment is used, the staging server must be able to access SMB (Windows File Sharing) files on the source server.

## General outbound from the Delphix Engine port allocation

Protocol	Port Numbers	Use
TCP	25	Connection to a local SMTP server for sending email

Protocol	Port Numbers	Use
TCP/UDP	53	Connections to local DNS servers
UDP	123	Connection to an NTP server
UDP	162	Sending SNMP TRAP messages to an SNMP Manager
TCP	443	HTTPS connections from the Delphix Engine to the Delphix Support upload server
TCP/UDP	636	Secure connections to an LDAP server
TCP	8415	Connections to a Delphix replication target. See <a href="#">Configuring Replication</a> .
TCP	50001	Connections to source and target environments for network performance tests.

#### General inbound to the Delphix Engine port allocation

Protocol	Port Number	Use
TCP	22	SSH connections to the Delphix Engine
TCP	80	HTTP connections to the Delphix GUI
UDP	161	Messages from an SNMP Manager to the Delphix Engine
TCP	443	HTTPS connections to the Delphix Management Application
TCP	8415	Delphix Session Protocol connections from all DSP-based network services including Replication, SnapSync for Oracle, V2P, and the Delphix Connector.
TCP	50001	Connections from source and target environments for network performance tests via the Delphix CLI.

#### Firewalls and Intrusion Detection Systems (IDS)

Production databases on source environments (for dSources) are often separated from the non-production environment by firewalls. Firewalls can add milliseconds to the latency between servers. Accordingly, for best performance, there should be no firewalls between the Delphix Engine and the virtual database (VDB) target environments. If the Delphix Engine is separated from a source environment by a firewall, the firewall must be

configured to permit network connections between the Delphix Engine and the source environments for the application protocols (ports) listed above.

Intrusion detection systems (IDSs) should also be made permissive to the Delphix Engine deployment. IDSs should be made aware of the anticipated high volumes of data transfer between dSources and the Delphix Engine.

## Adding a windows environment

This topic describes how to add a Windows environment to the Delphix Engine for use with unstructured files.

All Windows source and target environments containing unstructured files must have the Delphix Connector installed to enable communication between the environment and the Delphix Engine. The instructions in this topic cover initiating the Add Target process in the Delphix Management application, running the Delphix Connector installer on the environment, and verifying that the environment has been added to the Delphix Engine.

### Prerequisites

- Make sure your source and target environment meet the requirements described in [Requirements for Windows Environments](#).

### Procedure

1. From the machine that you want to use, log in to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Next to **Environments**, click the **Actions** menu and select **Add Environment**.
5. In the **Add Environment** wizard Host and Server tab, select:
  - a. Host OS: **Windows**
  - b. Host Type: **Target**.
  - c. Server Type: **Standalone**.
6. Click **Next**.
7. In the Environment Settings tab click the download link for the **Delphix Connector Installer**. The Delphix Connector will download to your local machine.
8. On the Windows machine that you want to use as a target, run the Delphix Connector installer. Click **Next** to advance through each of the installation wizard screens.  
The installer will only run on 64-bit Windows systems. 32-bit systems are not supported.
  - a. For **Connector Configuration**, make sure there is no firewall in your environment blocking traffic to the port on the target environment that the Delphix Connector service will listen to.
  - b. For **Select Installation Folder**, either accept the default folder or click **Browse** to select another.
  - c. Click **Next** on the installer's final 'Confirm Installation' dialog to complete the installation process and then **Close** to exit the Delphix Connector Install Program.
9. Return to the Delphix Management application.
10. Enter the **Environment Name, Host Address, Delphix Connector Port, OS Username, and OS Password** for the target environment.
11. To provide your own Oracle Java select the **Provide my own JDK** checkbox and click **Next**.
12. In the Java Development Kit tab enter the absolute path to your Oracle JDK and click **Next**.
13. Click **Submit**.

As the new environment is added, you will see two jobs running in the **Delphix Admin Job History**, one to **Create and Discover** an environment, and another to **Create** an environment. When the jobs are complete, you will see the new environment added to the list in the **Environments** panel.

### Post-requisites

1. On the Windows environment, in the **Windows Start Menu**, select **Services**.
2. Select **Extended Services**.
3. Make sure that the **Delphix Connector** service has a Status of **Started**.
4. Make sure that the **Startup Type** is **Automatic**.

### Options for linking unstructured files on Windows environments

There are two techniques for linking a new dSource from files on a Windows source.

#### Direct communication with the source environment

The simplest technique is to have the Delphix Engine communicate directly with the source environment. This requires installing the Delphix Connector on the source machine. When linking, specify a local path on the source machine, such as C:\Files\MyData.

#### Using a staging environment

In some cases, it is not possible or desirable to install the Delphix Connector on the source environment. In those cases, you can install the Delphix Connector on a "staging environment." This is another Windows machine that will act as an intermediary between the Delphix Engine and the source environment. Files on the source must be accessible by the environment user from the staging environment via a UNC path. Specifically, the environment user is only required to have READ access to the path, its directories, and files so that the robocopy utility called from the staging host can function properly. For example, use Windows Sharing on the source machine. When linking, specify the UNC path to the files on the source – for example, \\MySource\MyData\

For more information on installing the Delphix connector, refer to [Installing the Delphix Connector Service on the Target Database Servers](#).

## Linking unstructured files

### Prerequisites

- The source environment must meet the requirements outlined in [Unstructured Files Environment Requirements](#).
- The Delphix Engine must have access to an environment user. This user should have read permissions on all files to be cloned.

#### **Unstructured Files on Cluster Environments**

Unstructured files cannot be linked from, or provisioned to, any form of a cluster environment, such as an Oracle RAC environment. To link or provision unstructured files from a host that is part of a cluster, add the host as a standalone environment. Then link from, or provision to, this standalone host.

### Procedure

1. Log in to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Environments**.
4. Select the **environment** containing the unstructured files you want to link.
5. Click the **Environment Details** tab.
6. If the environment user described in the Prerequisites section is not listed under **Environment Users**, add the user.
7. Click the **Databases** tab.
8. Scroll to the bottom of the page to view the **Unstructured Files** section.
9. Click the **Plus** icon on the right. This action displays a dialog box prompting for the **Database Name** and **Path**. Enter a name to help identify the files. The path is the absolute path to the directory on the environment server.
10. Click **Add** to save the configuration. After saving this configuration, add the dSource.
11. Click **Manage > Datasets**.
12. On the left-hand side, click the **plus** sign.
13. Select **Add dSource**. Alternatively, on the **Environment Management** screen, you can click **Add dSource** next to a dataset name to start the dSource creation process.
14. In the **Add dSource** wizard, select the source of the files.
15. Select the **Environment User** outlined in the Prerequisites section.
16. Click **Advanced**.
17. Enter **Paths to Exclude**. These paths are relative to the root path of the dataset home path and will not be linked by the Delphix Engine. This feature is most commonly used to exclude directories containing log files. *Wildcard (\*) pattern matching is supported to exclude all the contents of a directory, without excluding the directory itself. For example, specifying `/dir/` will exclude all contents of `/dir` but still link `/dir` as an empty directory. For PowerShell to escape a \$ sign in a directory path please use the following `/ before the dollar sign` when adding it to the exclude paths, for example: `/ $RECYCLE.BIN`.*

#### **Info:**

##### Retroactive Edits to Exclude Paths on Windows

After creating a dSource, you can edit the set of **Paths to Exclude** from syncing at any time on the dSource's **Configuration** tab. For Unix environments, retroactively adding a path to exclude will result in the next SnapSync deleting the newly-excluded files. However, for Windows environments, retroactively adding a path to exclude will result in the next SnapSync ignoring newly-excluded files. Stale versions of these files will still exist in all future snapshots.

18. If you are linking files from a Unix environment, enter **Paths of Symlinks to Follow**. These paths are relative to the root path of the dataset home path and will be followed to gather additional files to copy.

**Info:**

Paths of Symlinks to Follow - Caveats

- This feature can only be used to follow symlinks to directories. Symlinks to files will be ignored.
- This feature is not available for files on Windows environments.

19. Click **Next**.
20. Enter a **dSource Name**.
21. Select a **Database Group** for the dSource.
22. Click **Next**. Adding a dSource to a database group enables you to set Delphix Domain user permissions for that dSource's objects, such as snapshots.
23. Select a **SnapSync** policy.
24. Click **Advanced** to edit retention policies.
25. Click **Next**.
26. Enter any operations that should be run at **Hooks** during the sync process (or any future sync processes).
27. Click **Next**.
28. Review the **dSource Configuration** and **Data Management** information.
29. Click **Submit**.

The Delphix Engine will initiate two jobs to create the dSource, **DB\_Link**, and **DB\_Sync**. You can monitor these jobs by clicking **Active Jobs** in the top menu bar, or by selecting **System > Event Viewer**. When the jobs have been completed successfully, the file's icon will change to a **dSource** icon on the **Environments > Databases** screen, and the dSource will be added to the list of **Datasets** under its assigned group.

**dSource Information**

After you have created a dSource, you can view information about it and make modifications to its policies and permissions by selecting it in the **Datasets** panel.

## Create an empty VDB for unstructured files in the Delphix Engine

This topic describes the procedure for creating an empty VDB, used for unstructured files. The term "unstructured files" in Delphix refers to a dataset that acts as a directory of different files. An empty VDB for unstructured files is not a database and does not receive special treatment or processing by Delphix, it exists as a place for the files to be generated, tracked, and copied. Creating a VDB can be done with provisioning from an existing dataset (a dSource or another VDB) or as an empty VDB created and filled with data.

Creating an empty VDB places an initially-empty mount on target environments. It functions similar to a VDB created via provisioning except it cannot refresh. Refreshing a dataset means overwriting the dataset content with new data pulled from the dataset parent. If a new VDB is created from scratch, the newly-created dataset will not have a parent and cannot be refreshed. All other functions are identical, meaning that the new VDB for unstructured files can be provisioned from, rewind, take snapshots, and so on.

### Prerequisites

The target environment must meet the requirements outlined in [Unstructured Files Environment Requirements](#).

**i Unstructured Files on Cluster Environments**  
 You cannot create an empty VDB on any form of the cluster environment, such as an Oracle RAC environment. To create an empty VDB on a host that is part of a cluster, add the host as a standalone environment, then create the empty VDB on the standalone host.

### Procedure

To create an empty VDB without provisioning:

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **plus** icon.
5. Select **Create Empty VDB**.
6. Click **Next** to go to the Target environment tab and do the following:
  - a. Under Environment, select a target environment where your empty VDB will be placed.
  - b. In the **Mount Path** field, enter the absolute path where the empty VDB/dataset will be mounted.
  - c. Click **Next**.
7. On the **Configuration** tab, do the following:
  - a. In the **Empty VDB name** field, enter a name for the VDB.
  - b. Select a target group for the empty VDB.
  - c. Select the **Enable auto-restart of the empty VDB** checkbox to allow VDB to be automatically restarted when the target host is rebooted.
  - d. Click **Next**.
8. On the **Policies** tab, select a Snapshot Policy for the empty VDB.
9. (Optional) On the **Hooks** tab, select a hook point and then click + to add a script to run at that point. Click **Next**.
10. The **Summary** tab will enable you to review your configurations. Click **Submit**

After the operation completes, the empty VDB will appear in the Datasets panel.

## Provisioning unstructured files as vFiles

### Overview

This topic describes the process of provisioning to a set of unstructured files as vFiles.

### Prerequisites

- You will need an unstructured files dSource, as described in [Linking Unstructured Files](#), or an existing vFiles from which you want to provision another.
- The target environment must meet the requirements outlined in [Unstructured Files Environment Requirements](#).

#### **i** Unstructured Files on Cluster Environments

Unstructured files cannot be linked from, or provisioned to, any form of a cluster environment, such as an Oracle RAC environment. To link or provision unstructured files from a host that is part of a cluster, add the host as a standalone environment. Then, link from or provision to this standalone host.

### Post provision/migration ownership rules

When a new vFile VDB is provisioned, the ownership is changed to match the Environment User anytime a VDB is enabled. This could cause conflict in the ownership of existing files in a case where the VDB has just been migrated to a new host – the VDB files on the new host will now be owned by the new Environment User.

### Procedure

1. Login to the **Delphix Management** application.
2. Click **Manage**.
3. Select **Datasets**.
4. Select a **dSource** or **vFiles**.
5. Click the **TimeFlow** tab.
6. Select a **snapshot**.
7. Click **Provision**. The **Provision vFiles** panel will open, and the field **Mount Path** will auto-populate with the path to the files on the source environment.
8. Select a target environment. If you need to add a new target environment for the vFiles, click the **Plus** icon next to **Filter Target** to add an environment.
 

**Note:** You can only target a Unix environment when provisioning from a Unix dSources or vFiles. You can only target a Windows environment when provisioning from a Windows dSources and vFiles.
9. If necessary, modify the **Mount Path**.
  - On Windows, this mount path must not be a UNC path. It must be a local drive letter and folder path. The UNC path will operate after the provisioning completes.
  - On Linux and Unix hosts, this mount path must be the full path and not include symlinks.
10. Click **Advanced**.
11. Enter **Additional Mount Points**. When it is mounted to the target environment, the vFiles will be mounted to any additional mount points you provide.
 

**Note:** The **Shared Path** is a relative path dictating which portion of the vFiles should be available on the additional environments. To share the entirety of the vFiles, specify a **Shared Path** of **/**.
12. Select an Environment User to own the mounted files. If the files are being mounted to multiple environments, ensure this user is available across all environments.
13. Click **Next**.

14. Enter a vFiles **Name**.
15. Select a **Target Group** for the vFiles. If necessary, click the **Plus** icon to add a new group.
16. Select a **Snapshot Policy** for the vFiles. if necessary create a new policy.
17. Click **Next**.
18. Enable Auto VDB Restart to allow the VDB to be automatically restarted when the target host reboot is detected by Delphix.
19. Enter any operations that should be run as Hooks during the lifetime of the vFiles.
20. Click **Next**.
21. Click **Submit**.

When provision starts, the vFiles will appear in the Datasets panel. Select the vFile and navigate to the Status tab to see the progress of the job. When provisioning is complete, you can see more information on the Configuration tab.

## Managing vFiles

### Overview

This article is used to cover steps on adding an additional mount to an existing vFile and outlining post provision/migration ownership rules.

### Adding an additional mount

1. Login to the **Delphix Management** application.
2. Select the **vFile** you want to edit.
3. From the Actions menu (...) select **Disable**.
4. In the **Configuration** tab select the **Source** sub-tab, a Pencil icon will appear on the right of the Additional Mount Points.
5. Click on the **Pencil** to edit the mount points.
6. In the **Additional Mount Points** window select the **Plus** icon to add additional mount points.
7. Click the **checkmark** to save.
8. From the Actions menu (...) **Enable** the vFile.

### Post provision/migration ownership rules

When a new vFile VDB is provisioned, the ownership is changed to match the Environment User anytime a VDB is enabled. This could cause conflict in the ownership of existing files in a case where the VDB has just been migrated to a new host – the VDB files on the new host will now be owned by the new Environment User.

## vFiles best practices and common pitfalls

### Overview

This document is the implementation guide for the best practices of implementing data source integrations using the Delphix vFile functionality provided through the AppData toolkit. Since "unstructured files", or vFiles, typically is implemented for non-DBMS file types, this implementation will require a certain degree of configuration and scripting in order to function. This means that while you do get some of the main functionality of the Delphix Engine, there are also quite a few pitfalls that may deter customers from wanting this type of configuration. Using vFiles and scripts to implement data source ingestion is a workaround that should only be used if you and the customer are fully aware of the best practices and limitations as called out below.

### Best practices and implementation

In order to be successful with this workaround, please keep in mind these best practices which will enable you to be successful in implementing a vFile configuration for data sources.

- Write a script to put the RDBMS into 'Backup' mode to prepare it for the next set of scripts Delphix will perform
- Create tablespaces in the RDBMS which dxtoolkit will take snapshots of while the database is in backup mode
- After any vFile provisioning job, script a recovery of the RDBMS instance

### Common use cases

These use cases are the typical scenarios for which you would use this workaround.

#### Unsupported DBMS configuration

This functionality is most appropriate when a customer is using an unsupported data source and wants a quick MVP to demonstrate the value of Delphix. It is critical to understand the pitfalls of this implementation and what value propositions that this excludes so that the customer is aware of what capabilities our core integrations provide.

### Common pitfalls

These pitfalls of functionality should be considered whenever implementing vFile scripted ingestion. Refer to the table for a quick reference of pitfalls.

Pitfall	Description
LogSync	Not Available
Point in Time Recovery	Not Available
Clustering	Not Available
User Interface	Not Available

Pitfall	Description
Production Downtime	Yes
Use of dxtoolkit	Requires Training

### LogSync and Point in Time provisioning

Since these scripts are taking full backups of the database, there will not be logs available for us to sync with. Therefore, point in time provisioning is not available to any vFile implementation.

### Manual operations

Currently, customers using this workaround have to perform the scripts manually. This creates operational overhead for customers, particularly their DBA team.

### Clustering

Using vFiles is not available for clustered instances, and there is currently no workaround for this type of configuration.

### Lack of Graphic User Interface (GUI)

Scripts perform all the core functionality that is typically carried out in the Delphix GUI. This implementation precludes the usage of the main GUI and is only accessible via the Command Line Interface (CLI).

### Production downtime

As the database enters backup mode during the ingestion process, this workaround causes the production source to go down while Delphix ingests their data.

### Understanding and implementing scripts and dxtoolkit

Implementing these scripts requires an understanding of dxtoolkit and the data source which you are trying to integrate with. Typically, we estimate the learning period of this to be about 1 - 2 months to fully understand how to use these tools and how to best implement the scripts for any given source.

### Conclusion

Using vFile functionality with scripts is a quick way to demonstrate the value of the Delphix Engine easily. With a little scripting and Delphix knowledge, you can engineer ingestion with dxtoolkit to take snapshots of the entire database. However, there are several pitfalls that every customer should know about and understand before moving forward with this type of implementation. If you have any questions, please reach out to Product Management.

## Delphix Engine plugin management

### Plugin management

This section provides information on the data management plugin deployed on the Delphix Engine. Users can directly upload their Plugins to the Delphix Management application with a single click, thus eliminating the process of uploading the Plugin using the command. Plugin upload via the Delphix Management application helps users to build their Plugin library in a simple and easy-to-use manner.

The Plugin screen allows users to view a structured or formatted view of their selected Plugin and it provides a single click option for users to delete a Plugin.

Only Admin users are able to upload or delete Plugins. Standard users are only able to view Plugin information.

### Plugin types

There are two types of plugins the Delphix engine supports Lua/Python plugins and platform plugins. Because support for these types of plugins was written at different times, the upgrade and replication workflows will differ depending on what the plugin type is. To figure out what type of plugin this is, follow the instructions below:

1. Login to the **Delphix Management** application.
2. Select **Manage > Plugins**.
3. Select the plugin you want to check and look for the type field in the details section on the right.
4. If the type is Toolkit this means the plugin is a Lua plugin. If the type is Plugin, then the plugin is either a platform plugin or a python plugin.

### Installation of plugin

Plugins can be uploaded onto the Delphix Engine only by an admin.

#### Prerequisites

- Make sure you have access to a copy of the plugin from the computer you will be installing.
- Verify with the plugin author that the version of the plugin you have is compatible with your Delphix Engine version.

#### Procedure

To add or upload a new Plugin complete the instructions below:

1. Login to the **Delphix Management** application.
2. Select **Manage > Plugins**.
3. To add or upload a Plugin, click the  icon. This opens the Upload or Upgrade Plugin dialog.

4. To start using the plugin, refresh target and source environments to discover any repositories.

## Upgrading a plugin

When a new version of a plugin is released, the new plugin can only be uploaded onto the Delphix Engine by an Admin.

### Prerequisites

- Make sure you have access to a copy of the plugin from the computer you will be installing.
- Verify with the plugin author that the new version of the plugin is compatible with your current version, and with your Delphix Engine version.
- If the already-installed plugin does not use the Lua language, then you don't have to disable any dSources or VDBs. However, be aware that you will not be able to perform any Delphix operations on them while the plugin is being upgraded.

### Procedure

To upgrade a Plugin just follow the instructions above on how to upload a Plugin. The newly-uploaded plugin will be used to upgrade any already-present version(s) of the same plugin.

## Notes on replication with objects administered by a plugin

Replication works the same way for objects created with plugins and objects created using natively supported data types. But, complications and problems can arise when a replicated plugin's version does not match the version of the installed plugin.

### **i** Replication Recommendation

As discussed in the section on [Delphix Replication Overview](#), we highly recommend that replication target engines be used solely to hold replicated objects, and that failover is only done in disaster recovery situations. Or, at the least, make sure that the versions of replicated plugins match the versions of plugins that are already installed on the replication target engine.

There are specifically two operations done after replication that will be listed below.

Provisioning from replicated data sources or VDBs

Replica provisioning is only guaranteed to work when the source object's plugin is already also installed on the target engine with the identical version.

Installed Plugin Version	Result
None	Replica provisioning will fail.
Lower than replicated version	Replica provisioning will fail.
Same as replicated version	Replica provisioning will succeed.
Higher than replicated version	If the replicated plugin uses the Lua language, replica provisioning will fail. If the replicated plugin does not use the Lua language, replica provisioning may or may not succeed, depending on whether the installed plugin is compatible with the replicated version.

More general information on how to perform a replica provision can be found [here](#).

Failing over a replica

As mentioned above, we strongly recommend that replication target engines do not have any non-replica objects. Although the replica failover process will always work, the failed-over objects may or may not be fully functional if there are non-replica plugin-administered objects already on the same engine. In some cases, you may have to delete some objects, and their associated plugins.

Installed Plugin Version	Result
None	The replicated plugin and its objects will be moved into the live namespace. All failed-over objects will be fully functional.

Installed Plugin Version	Result
Lower than replicated version	The failed-over objects may become "inactive", and any Delphix operations run on them will fail. In this case, you can try to upgrade the existing plugin so that the version matches the replicated inactive plugin. This may or may not work, depending on whether there are any conflicts between any objects.
Same as replicated version	The failed-over objects will be fully functional.
Higher than replicated version	The failed-over objects will become "inactive", and any Delphix operations run on them will fail. In this case, you can try to upgrade the inactive plugin (see instructions below). Again, this may or may not work, depending on whether there are conflicts between any objects, and on whether the installed plugin knows how to interact with the inactive plugin.

More generic information on how to perform an actual failover can be found [here](#).

### Upgrading an inactive plugin

If a failed-over plugin becomes "inactive" (see details above), you may be able to activate the plugin by upgrading it to match the version of the installed plugin.

#### Procedure

To upgrade an inactive Plugin complete the instructions below:

1. Login to the **Delphix Management** application.
2. Select **Manage > Plugins**.
3. In the drop-down menu on the left, select the plugin that is inactive.

#### Plugins

Pretty Name	Version	Namespace
Unstructured Files	1.0.0	
nix_staged_python	2.1.0	
nix_staged_python	2.0.0	

```

object {23}
  externalVersion : 2.0.0
  buildNumber : 2
  ▶ virtualSourceDefinition {2}
  ▶ linkedSourceDefinition {2}
  ▶ discoveryDefinition {8}
  ▶ upgradeDefinition {1}
    entryPoint : operations.nix_staged:staged
    sourceCode : *****
  ▶ manifest {21}
    status : INACTIVE
    
```

4. Click the upgrade button  which should be clickable now to activate the inactive plugins. Make sure to confirm the upgrade by selecting OK.

## Upgrade Plugin

Are you sure you want to upgrade "nix\_staged\_python" ?

Cancel

OK

5. After the upgrade is successful the inactive plugin of the lower version will not exist in the plugin list.

 If the inactive plugin is a higher version, the active plugin needs to be upgraded using the normal upgrade procedure instead.

## Unstructured files hook operation notes

### Shell Operations

#### RunCommand operation

The RunCommand operation runs a shell command on a Unix environment using whatever binary is available at `/bin/sh`. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command line interface (CLI) to aid in debugging.

If successful, the shell command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Examples of RunCommand operations

You can input the full command contents into the RunCommand operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"

if test -d "$remove_dir"; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

If a script already exists on the remote environment and is executable by the environment user, the RunCommand operation can execute this script directly.

```
/opt/app/oracle/product/10.2.0.5/db_1/dbs/myscript.sh "$ARG_ENVIRONMENT_VARIABLE"
"second argument in double quotes" 'third argument in single quotes'
```

#### RunBash operation

The RunBash operation runs a Bash command on a Unix environment using a `bash` binary provided by the Delphix Engine. The environment user runs this Bash command from their home directory. The Delphix Engine captures and logs all output from this command. If the script fails, the output is displayed in the Delphix Management application and command line interface (CLI) to aid in debugging.

If successful, the Bash command must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of RunBash operations

You can input the full command contents into the RunBash operation.

```
remove_dir="$DIRECTORY_TO_REMOVE_ENVIRONMENT_VARIABLE"
```

```
# Bashisms are safe here!
if [[ -d "$remove_dir" ]]; then
    rm -rf "$remove_dir" || exit 1
fi

exit 0
```

## Shell operation tips

### Using `nohup`

You can use the `nohup` command and process backgrounding from resource in order to "detach" a process from the Delphix Engine. However, if you use `nohup` and process backgrounding, you MUST redirect `stdout` and `stderr`.

Unless you explicitly tell the shell to redirect `stdout` and `stderr` in your command or script, the Delphix Engine will keep its connection to the remote environment open while the process is writing to either `stdout` or `stderr`. Redirection ensures that the Delphix Engine will see no more output and thus not block waiting for the process to finish.

For example, imagine having your `RunCommand` operation background a long-running Python process. Below are the bad and good ways to do this.

#### Bad Examples

- `nohup python file.py & # no redirection`
- `nohup python file.py 2>&1 & # stdout is not redirected`
- `nohup python file.py 1>/dev/null & # stderr is not redirected`
- `nohup python file.py 2>/dev/null & # stdout is not redirected`

#### Good Examples

- `nohup python file.py 1>/dev/null 2>&1 & # both stdout and stderr redirected, Delphix Engine will not block`

## Other operations

### RunExpect operation

The RunExpect operation executes an Expect script on a Unix environment. The Expect utility provides a scripting language that makes it easy to automate interactions with programs which normally can only be used interactively, such as `ssh`. The Delphix Engine includes a platform-independent implementation of a subset of the full Expect functionality.

The script is run on the remote environment as the environment user from their home directory. The Delphix Engine captures and logs all output of the script. If the operation fails, the output is displayed in the Delphix Management application and CLI to aid in debugging.

If successful, the script must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of a RunExpect Operation

Start an `ssh` session while interactively providing the user's password.

```
spawn ssh user@delphix.com
expect {
  -re {Password: } {
    send "${env(PASSWORD_ENVIRONMENT_VARIABLE)}\n"
  }
  timeout {
    puts "Timed out waiting for password prompt."
    exit 1
  }
}
exit 0
```

#### RunPowershell operation

The RunPowershell operation executes a PowerShell script on a Windows environment. The environment user runs this shell command from their home directory. The Delphix Engine captures and logs all output of the script. If the script fails, the output is displayed in the Delphix Management application and command line interface (CLI) to aid in debugging.

If successful, the script must exit with an exit code of `0`. All other exit codes will be treated as an operation failure.

#### Example of a RunPowershell operation

You can input the full command contents into the RunPowershell operation.

```
$removedir = $Env:DIRECTORY_TO_REMOVE

if ((Test-Path $removedir) -And (Get-Item $removedir) -is [System.IO.DirectoryInfo])
{
  Remove-Item -Recurse -Force $removedir
} else {
  exit 1
}
exit 0
```

#### Unstructured files environment variables

Operations that run user-provided scripts have access to environment variables. For operations associated with specific dSources or virtual databases (VDBs), the Delphix Engine will always set environment variables so that the user-provided operations can use them to access the dSource or VDB.

## dSource environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	Path where linked-staged database is mounted

## VDB environment variables

Environment Variable	Description
DLPX_DATA_DIRECTORY	Path where virtual database is mounted

## Best practices

For optimal usage of Delphix, there are many different configurations and best practices you'll need to note to tune your engines for peak performance. This ranges from settings on the hypervisor that runs Delphix to the setting on your sources, virtual databases, and the operating systems on which they run. Find out more information based on each category below.

These pages are the starting point to begin your architecture planning for the best possible Delphix deployment. To function as a high-performance virtual appliance, we need to ensure the underlying infrastructure components are deployed in an ideal manner consistent with our best practices - these pages are to help you achieve that goal.

## Architecture checklist FAQ

### Architecture best practices overview FAQ

These questions relate to the standard processes our Solutions Architecture team executes when engaged for Architecture review of a customer's environment.

#### Why go through an architecture or sizing process?

To measure - when possible - the workload in your environment and calculate the number of engines needed

- To ensure best practices are applied so your engine(s) perform to the level expected
- To find and avoid or work around potential challenges in an environment
- To maximize your license value

#### Why does Delphix collect IO data?

The collection of IO data allows us to more accurately size the Delphix Engine rather than making recommendations based on assumptions or synthetic data. The data you provide for analyses is from the SOURCE and TARGET DB servers.

#### Why is the customer database and inventory (CDI) important?

The database information is typically the fundamental building block upon which we build our understanding of your future Delphix environment. We ask questions related to the database names, locations, platforms, and versions, as well as estimates of size, throughput, and changes.

The answers you provide to our infrastructure questions give us insight into potential challenges that may arise as we seek to integrate our application and best practices into your environment. Processes and software you use normally may not integrate optimally into our engine, and it's helpful to know this as soon as possible.

#### Why does Delphix use a virtual machine? Shouldn't all high-performance applications use physical infrastructure?

Using virtualization not only allows our customers to use their choice of commodity hardware, but it also allows us to focus on core features rather than hardware support.

### Architecture best Practices for hypervisor host and VM guest - ESX FAQ

#### Why does Delphix recommend 8 vCPUs and 128GB of memory per 8 vCPUs?

8 vCPUs are not only a standard licensing block, but they are also key to meeting our 10Gbps single-engine throughput potential and help to sustain low latency for VDBs.

As with CPU, cache memory is required to drive peak loads on the Delphix Engine. More memory allows for more blocks to be read from the cache rather than going to less performant disks. Delphix stores cached data in a compressed format and only keeps a single copy of unique blocks in memory. These features give read performance across multiple VDBs provisioned from a single source dramatic improvements in speed, scalability, and memory utilization.

### Why does Delphix request reservations for CPU and memory?

Delphix performance can be greatly impacted there is contention over CPU or RAM. Reservations allow the engine to explicitly control those resources and avoids the possibility of contention with other VMs, even when resources are overcommitted.

### Why does Delphix request Hyper-Threading (HT) be disabled?

Hyper-Threading can have a positive impact on many, but not all applications. Delphix has a different execution profile that does not benefit from Hyper-Threading. Factors such as significant memory bandwidth requirements and a high level of parallelism which requires a high number of shared locks mean that HT and Delphix do not generally work well together.

### Why does Delphix request 4 controllers, and why must the storage be identical between them?

To provide optimal storage performance, you must spread data equally over the maximum (4) virtual SCSI controllers. To provide consistent performance between each of the four controllers, you need to ensure storage is identical between them.

### Why must virtual disks (VMDKs) be thick provisioned and eager-zeroed?

Thick provisioning and eager zero ensure performance is top-notch from the start with no hiccups from expanding virtual resources.

### Why is 20% free space required?

While the ZFS file system has a lot of features leveraged by Delphix, it loses efficiency as space decreases. 20% is the minimum that must be available for best performance.

### Why does Delphix request you reserve CPU and RAM for Hypervisor overhead?

Based on VMWare's resource management guide and our own experiences with high IO throughput. Note there is no specific mechanism to assign resources to the hypervisor, the only way to preserve overhead is by not allocating resources to guests.

### Why does Delphix generally want VMWare HA enabled, but DRS disabled?

VMware HA (High Availability) addresses outages that occur when a physical host goes down or is completely offline, by migrating the guest(s) to another physical host and restarting them. There is no real downside, it simply brings unavailable servers back online.

VMware DRS (Distributed Resource Scheduler) is for load balancing host resources in a cluster. Because of high IO and best practices configuration for optimal performance, our engine is typically not a good candidate for relocation.

### Why does Delphix request you set power management to High-Performance Mode?

This will ensure power management will never impact performance by entering into a lower power state (also known as c-state).

## Architecture best practices for storage FAQ

### Why does Delphix require 127GB of storage for the OS?

The system partition requires space to store and operate the OS, as well as application logs, upgrade and rollback images, and enough free space to store a kernel or application core dump should it be required.

### Why does Delphix require our LUNS to be uniform and contain an equal quantity and capacity of VMDKs, yet thin provisioning is OK?

Because our engine leverages parallel reads, we need the storage capacity and quantity of disks they hold to be consistent. This allows the reads and writes to be evenly distributed, and minimizes the impact of potential utilization imbalances which would create a “long tail” of higher latency on a single controller, impacting the entire engine.

Data storage LUNS are generally formatted with a VMFS file system and have placed upon them a virtual disk (VMDK) which is thick provisioned and eager zeroed, so it would be a waste of time to thick provision the LUN also.

### Why does Delphix require < 10ms latency (95th percentile) storage?

Storage latency is especially important in database environments. Average latency doesn't give a complete picture of responsiveness, especially because Delphix leverages parallel reads; so inconsistent performance (e.g. good average latency but a “long tail”) can impact multiple operations. This is why Delphix has a focus on 95th percentile latency, and why we validate storage performance as the first step when a new engine is deployed.

For more information, you may find the following article helpful: [The Cost of Latency](#).

### Why does Delphix prefer to extend existing storage rather than simply add more while maintaining equal distribution?

While it is possible to add more storage and maintain the practice that "storage should be equal across controllers" – extending LUNS (then virtual disks) ensures that:

- We do not continue to fill disks which may be full
- Existing disks do not suffer a write performance penalty from low capacity
- Storage performance is consistent

## Architecture best practices for network FAQ

### Why does Delphix request 10GE Ethernet?

As a matter of physics and standards - 10 gigabit (Gb) Ethernet can sustain approximately 1 gigabyte (GB) per second of throughput. With all our best practices applied, a Delphix Engine can achieve very close to that line speed, allowing for optimal load, engine, and license utilization. Lower network speeds may be acceptable for low loads, while in some environments NIC teaming (e.g. LACP) may be required for top speeds.

### Why does Delphix require < 1ms latency to TARGET servers and < 50ms to SOURCE servers?

Delphix leverages NFS and iSCSI (depending on platform) for live TARGET DB mounting over the network, so it's imperative that latency is as low as possible. Data coming from SOURCE servers is not generally as time-sensitive, so you need a minimum latency of < 50ms to ensure operational integrity.

## Why does Delphix request Jumbo Frames?

Jumbo frames increase the Ethernet maximum transmission unit (MTU) from the default 1500 bytes to 9000 bytes. This has several effects such as decreasing CPU cycles by transferring fewer packets and increasing the engine throughput. You will find jumbo frames have a 10-20% real-world impact and are required (along with all other best practices) to handle peak loads of 800 - 1000MB/s on an 8 vCPU engine with a 10Gb network.

## How does Delphix avoid communication impact with non-jumbo frame hosts when Jumbo Frames are enabled on the Delphix Host?

[Path MTU Discovery](#) is the mechanism by which two hosts agree on the MTU leveraged for communication between them. This mechanism will ensure communication between both standard and Jumbo Frame enabled hosts works as expected.

## When does Delphix recommend NIC teaming?

The Delphix Engine is capable of high throughput, but not every enterprise has sufficient network bandwidth to support it. Teaming is a less expensive way of increasing the bandwidth when compared to new hardware.

## Why does Delphix recommend logical and physical and co-location?

The Delphix Engine leverages network connections extensively, so optimizing the latency whenever possible is very important - sometimes critical.

## Architecture best practices for Delphix engine data protection FAQ

### Why does Delphix recommend SAN snapshots or Delphix replication for backup?

There are a few possible methods for data protection of the Delphix Engine. Those methods are SAN snapshots, Delphix replication, and virtual machine snapshots (for very small engines only). Because the Delphix Engine is itself a backup of source environments, many customers simply plan to rebuild in the event of a disaster.

### What is the DXToolkit, and how can it help?

The professional services team has created a Perl-based “DXToolkit” which can help export and import certain configuration data over web services. This toolkit can be leveraged to assist with would normally be a manual re-install outside of the above methods.

For further detail around data protection, please speak with your Delphix contact.

### Can I use a VMware-based backup solution such as VEEAM to backup my Delphix Engine?

Yes, VMWare backup solutions are useful for backing up guest VMs. However, Delphix suggests that you only use this approach for Delphix Engines which have a smaller storage footprint (perhaps < 2 TB) and are less active.

Running this type of backup puts a load on the environment, which might adversely impact Delphix VM performance.

### Can I use a VMware snapshot for backing up Delphix for a small window – for example, during an engine upgrade?

Yes. However, even though snapshots are instantaneous, they track changes separately from the base disks and can grow to consume as much space as the original.

Upgrades, in particular, can change substantial amounts of data.

If you lose physical disks, snapshots are useless because it needs them to make up the current state of VM.

A Delphix Engine is often allocated multiple terabytes of storage and is often very busy due to load aggregation from virtual databases on multiple target servers, so this approach may be challenging.

Snapshots cannot detect storage corruption.

Can I use a Storage snapshot solution to protect Delphix against Storage and Delphix corruption?

Yes. However, please note that the caveats which apply to VMWare snapshots will also apply here.

A specific concern related to storage layer snapshots is that you must create a consistency group that contains both the OS and Data disks.

Can I use RMAN to backup my VDBs just like a Physical database to provide extra protection?

You can backup Delphix VDBs using Oracle RMAN tools, but the recovery database would first require re-hydration of that VDB, which might take up equivalent production storage space.

Furthermore, that re-hydrated database needs to be brought into the Delphix framework as a dSource, after which you can provision a VDB to complete recovery. The whole process might take hours or days to recover.

The best approach is to use the VDB Snapshot capability to backup VDB frequently and then leverage Delphix Replication capability to protect underlying Delphix storage, which holds that VDB snapshot.

## Architecture checklist

### Overview

The Architecture Checklist is an overview combining the more important Architectural best practices into a single list. For more detail regarding some of the reasons for our best practices, review the Architecture Checklist FAQ.

## Architecture best practices for hypervisor host and VM guest - ESX

### Hypervisor

1. ESXi [6.x](#) or 7.0 is recommended. ESXi 5.5 or earlier is no longer supported.
2. HyperThreading (HT) for Intel®-based servers (no HT on AMD CPUs).
  - a. Disable HT in BIOS, on the ESXi Host, **and** disable [HT Sharing](#) on the Delphix VM for consistency. This is our best practice, disable at all levels. Any other combination may result in non-deterministic performance.
  - b. When HT cannot be turned off for both the Host and Delphix VM, it should be turned on at all levels, not run in a "mixed-mode".
    - i. HT disablement at a guest level only can result in non-deterministic performance.
    - ii. A dedicated ESXi host, cluster or DRA is recommended where consistent VDB performance is paramount.
  - c. VM migration to a new host (e.g. VMware HA or vMotion) can create mismatched HT settings.
3. ESXi overhead (resources required for hypervisor cannot be reserved, they must be left unallocated).
  - a. Memory Overhead - 10% of available RAM must not be allocated to guest VMs.
    - *Example: 256GB RAM, allocate 230GB to Delphix VM, leave 26GB for ESX*
  - b. CPU Overhead - At least 2 cores (ideally 4) must not be allocated to guest VMs.
    - *Example: If 16 physical cores are available, allocate 12 to the virtual machines, leaving 4 for the hypervisor*
    - *Why 4? Certain hypervisor functions require precedence over any virtualized system. If a hypervisor needs more CPU than the amount currently available, it can de-schedule all other virtual processes to ensure adequate CPU resources for the hypervisor. Ensuring the hypervisor will not have to de-schedule any running virtual processes (worlds) by setting aside and not over-subscribing CPUs for virtual functions will leave them available for hypervisor use.*
  - c. Even if the Delphix VM is the only VM on a host, the hypervisor is still active and essential; and still needs resources.
4. BIOS Power Management should be set to High Performance where ESXi controls power management.
  - a. Can be impacted by [VMware KB 1018206](#) - poor VM application performance caused by power management settings.
  - b. Ensure that all BIOS managed C-States other than C0 are disabled if power management is hardware controlled.
  - c. Ensure that all ACPI sleep states above S0 are disabled in the BIOS.
  - d. Examples for popular server lines from Cisco, HP, Dell below. *Specific models will vary, use the appropriate spec sheet.*
    - i. UCS: disable the Processor Power States, disable Power Technology, set Energy Performance to "Performance"
    - ii. HP Proliant: set HP Power Regulator to HP "Static High Performance" mode
    - iii. Dell: set BIOS System Profile to "Performance Optimized" mode
5. VMware HA can be enabled; VMware DRS is generally disabled.
6. Blade/Rack Server Firmware and ESXi Drivers should be updated to latest versions.

7. For Intel®-based servers with E5-2600 v2 processors.
8. Two typical server configurations:
  - a. Blade Farm
  - b. Rack Server Hyper-Converged configurations are possible for high performance.

## Virtual Machine Guest

1. For VM machine settings, see [Virtual Machine Requirements for VMware Platform](#).
2. VMWare Guest Specifications:
  - a. Minimum: 8 vCPU x 64 GB Small: 8 vCPU x 128GB Medium: 16 vCPU x 256 GB Large: 24 vCPU x 512 GB
  - b. Reserve 100% of RAM and CPU:
    - If the ESX host is dedicated to Delphix, CPU and RAM reservations are advised but not necessary, however, swap space will be required on the hypervisor to compensate for the lack of reserved RAM.
  - c. [Hyperthreading](#) - See the ESX host section at the top. Disable HT Sharing on VM, disable HT on ESX Host.
3. Assign single-core sockets for vCPUs in all cases. If there is a compelling reason to use multi-core CPUs, reference the following article from VMware which describes matching virtual multi-core sockets to the hardware ESX is running on. [VMware Article on CoresPerSocket](#) Example: *ESXi Host has 2 socket x 18 core Intel Xeon, Delphix Engine wants 16 vCPU*. Configure Delphix VM with 2 Virtual Sockets, 8 Cores Per Socket to utilize hardware architecture.
4. Avoid placing other extremely active VMs on the same ESX host.
5. Monitoring - vSphere Threshold Alerts for CPU, Network, Memory, Capacity.
6. To set the number of vCPUs per virtual machine via the vSphere client, please see "[Virtual CPU Configuration](#)" in the Administration guide:  
[ESXi 6.0](#)
  - a. [Delphix VM CPU Utilization](#) - Delphix KB article on what makes Delphix VMs similar to other resource-intensive applications
  - b. [Exchange on VMware Best Practices](#) - VMworld 2013 session
  - c. [ESXTOP Reference, Blog](#)
7. Ensure that the latest available VMware drivers and firmware versions are installed for HBAs, NICs and any other hardware components configured on the Delphix virtual machine. This is a critical step that can have a massive impact on the performance and robustness of our solution.

## Architecture best practices for network configuration

1. For more information about network configuration refer to [Network Performance Configuration Options](#).
2. Delphix Engine <====> Target Host: *Implement standard requirements for optimal NFS/ISCSI performance*:
  - a. Optimal physical network topology:
    - Low latency: < 1ms for 8K packets.
    - Network adjacency: minimize network hops, co-locate in the same blade enclosure, co-locate on the same physical host.
    - Eliminate all Layer 3+ devices - firewalls, IDS, packet filters (Deep Packet Inspection - DPI).
    - Multiple switches can add latency and fragmentation and reordering issues will add significant latency.
  - b. Optimal throughput:
    - 10GbE physical uplinks or higher.
    - Jumbo frames (typically MTU 9000) improves network efficiency for 8K packets: lower CPU, lower latency, greater throughput.
    - All devices end-to-end *must* be configured for the larger frame size including switches, routers, fabric interconnects, hypervisors and servers.
    - Traffic between two VMs on the same host is limited to ~16Gbps when leveraging built-in virtual networking.

- c. Optimal logical flow:
  - Disable QoS throttles limiting network utilization below line rate (e.g. HP Virtual Connect FlexFabric).
  - Consider a dedicated VLAN (with jumbo frames) for NFS/iSCSI traffic.
    - [VMware KB-Configuring iSCSI port binding with multiple NICs in one vSwitch for VMware ESXi 6.0.x \(2045040\)](#)
    - [VMware KB-Considerations for using software iSCSI port binding in ESX/ESXi \(2038869\)](#)
- d. NIC Teaming (at ESX layer) of multiple physical uplinks can provide additional throughput for higher workloads.
  - i. Examples: 4 x 1Gb NICs support up to 400 MBPS IO, 2 x 10Gb NICs support up to 2 GBPS IO.
  - ii. [VMware KB-1004088](#) has NIC teaming recommendations, including `route-based-on-IP-hash` policy.
  - iii. [VMware KB-1001938](#) has host requirements for physical link aggregation (LACP, EtherChannel).
  - iv. [VMware KB-1007371](#), [popular blog post](#) details problems with NIC selection using `dest-IP hash`.
- e. Fragmentation and dropped packets can result in excessive retransmissions of data, reducing throughput.
  - i. On AIX, LSO (Large Send Offload) and LRO (Large Receive Offload) network features have caused many problems. The virtualization engine employs LSO only, but no LRO, AIX employs both. These features are enabled by default. The best practice is to disable LSO on the VE when the target is AIX.
    - LSO enabled on the Virtualization engine can result in dramatically limited or blocked transmit throughput (and increase re-transmission traffic).
    - When wishing to disable all, LSO should be disabled on the Delphix Virtualization Engine, while both LRO and LSO should be disabled on guest VM of AIX Target. The specific commands to disable LSO and LRO on AIX are not captured here and appear to be context/version-specific.
- f. **Jumbo frames check via ping**

```
Delphix Engine
$ ping -D -s [Target_IP] 8000
"ICMP Fragmentation needed and DF set from gateway" indicates MTU < 8028

Linux
$ ping -M do -s 8000 [Delphix_Engine_IP]
"Frag needed and DF set (mtu = xxxx)" indicates MTU < 8028

MacOS
ping -D -s 8000 [Delphix_Engine_IP]

Note: "sudo sysctl -w net.inet.raw.maxdgram=16384" will increase the max
ICMP datagram size on Mac, allowing you to use -s 9000 on Mac0

Windows
ping -f -l 8000 [Delphix_Engine_IP]

http://www.mylesgray.com/hardware/test-jumbo-frames-working/
```

- g. Measure Network Bandwidth and Latency:
  - i. Latency in both directions should be < 1ms for an 8KB payload.

- ii. Network Hops should be minimized: `tracert` (Unix/Linux) / `tracert (windows)`.
- iii. Throughput in both directions: 50-100 MB/s on 1 GbE, 500-1000 MB/s on 10 GbE physical link.
- iv. Always use the CLI when possible.
- h. NIC should use Auto-negotiate on Ethernet with a minimum of 1000Mbps.
  - Hard setting speed/duplex will limit network throughput below the line rate.
- 3. **Delphix <====> Staging Server**(SQL Server, Sybase):  
Measure latency, bandwidth for transaction log restore performance
- 4. **Source <====> Delphix**: Measure latency, bandwidth to explain snapsync performance
- 5. **ESX host <====> ESX host**(ESX Cluster):
  - a. This is because the entire memory footprint of the Delphix VM (more precisely, the entire address space of the ESX processes that comprise the VM) must be copied to the receiving ESX host, along with all changes to that address space as they happen. Our ZFS cache comprises the bulk of that memory and changes as I/O occurs, and that rate of change is governed by the network bandwidth available to the Delphix Engine.
  - b. Attempting to live vMotion a DE with a 10Gb NIC over a 1Gb vMotion network is thus likely to fail.

## Architecture best practices for storage

1. Configuration:
  - a. Virtual Disks (VMDK) with spinning or tiered media must be thick provisioned + lazy zeroed.
    - For storage which is 100% SSD/EFD/Flash-based, continue to thick provision, however, eager zero is not necessary.
  - b. VMDKs may be homed on VMFS or RDM storage, however, VMFS is much more common and generally preferred.
  - c. Regardless of VMFS/RDM selection, physical LUNs must have uniform characteristics (RAID, spindle count, tier) and should be thin provisioned to save time.
  - d. Storage allocated must be identical between each vSCSI controller.
  - e. The supported maximum of four virtual SCSI controllers (PVSCSI (default) or LSI Logic Parallel) must be enabled. A mix of different types of SCSI controllers is not supported within the engine.
  - f. Virtual Disks must be evenly distributed across the 4 virtual SCSI controllers. For example, 8 virtual disks should be configured as 2 disks per controller: SCSI (0:0), SCSI (0:1), SCSI (1:0), SCSI (1:1), SCSI (2:0), SCSI (2:1), SCSI (3:0), SCSI (3:1).
    - You don't need to account for the OS in the even distribution of disks across controllers, just pick one; the OS doesn't place a substantial load on the controller.
  - g. To provision VMDK disks over 16TB in size, the vSphere web client must be used, the win32 client will return an error.
  - h. As of 5.1.3, we require 127GB for the system disk. older versions defaulted to 150GB.
    - Due to our unified OVA for masking, the 127GB requirement also applies to Masking Engines
  - i. VMDK for the Delphix Engine OS is often stored on the same VMFS volume as the Delphix VM definition file (aka VMX). In that case, the VMFS volume must have sufficient space to hold the Delphix VMX Configuration, the VMDK for the system disk, a swap/paging area if the memory reservation was not enabled for the Delphix Engine (or to suspend the system), and any related VMware logging.
  - j. Set ESX Storage Multipathing IO optimization ([KB 2072070](#)).
    - i. Set multipathing policy to round-robin.
    - ii. Set path switching IO operation limit to 1 (default 1000).
  - k. Verify that the queue depth setting on the virtual disks used for VMware is appropriate based on the minimum of the HBA type or the underlying storage's combined queue depth for all hosts attached to the same controller
    - See this [VMware KB article](#) for how to check/set the queue depth
2. Testing:

- a. Run Storage Performance Tool on the raw storage **before any engine configuration**. This is a one-time opportunity for each engine upon installation
  - b. Required maximum storage latency is < 2ms for writes and < 10ms (95th percentile) for small random reads. Minimum passing grades: 4KB/8KB reads (B-), 1MB reads (A), 1KB/128KB writes (A).
  - c. If working with the Delphix Professional Services team, we would expect to run additional baseline performance measurements via composite tools and scripts.
    - e.g. "Sanity Check" (Oracle) or "DiskSpd" (MSSQL)
3. Detail Discussion:
- a. Before beginning any discussion on storage performance, or at the beginning of the installation, collecting the following specs from your storage administrator will assist in understanding
  - b. Vendor, Model (For example: EMC VMAX 40k, HP 3PAR StoreServ 7000)
  - c. IO latency SLO (For example 5ms 99.999%)
  - d. IOPS/GB SLO (For example: 0.68 IOPS/GB for EMC Gold-1)
  - e. Cache type and size (For example FAST cache 768GB)
  - f. Tier, #Pools; if auto – tiering; relocation schedule (For example: Gold/Silver/Auto/3 pools/etc)
  - g. Pool detail: (#) drives, RPM, Type (For example: Pool1: (20) EFD, (30) 15k SAS, Pool 2: (40) 10k SATA)
  - h. Connection (For example: 16Gb Fibre Channel, 10Gb iSCSI, 20Gb N

## Architecture best practices for Delphix engine data protection

1. For protection against physical host failure - leverage VMware HA.
2. For protection against storage failure - leverage Delphix replication.
3. For protection against administrative error - leverage storage snapshots.
4. For protection against site failure - leverage Delphix replication and/or Delphix Live Archive.
5. Infrastructure Backup of the Delphix VM: Must take a consistent group snapshot of all Delphix VM storage (system disk, VM configuration, database VMDK/RDMs) RTO, RPO are inferior compared to Delphix Replication. The granularity of restore is at the VM level: **all-or-nothing**.
  - a. Virtual Machine Backup: Create VM snapshot, backup (proxy server), remove the snapshot. Products use VMware APIs: NBU for VMware, TSM, Networker Limited to < 2TB because of time to backup, impact on running VM
  - b. Storage Array Backup: Take a consistent storage snapshot, replicate to tape/VTL media server, remove the snapshot. Products include Hitachi Shadow Copy, EMC SnapCopy, HP Business/Snap Copy.

## Architecture best practices for Masking

1. As of release 5.0, the virtualization and masking functions are combined into a single OVA and require additional consideration for installation and configuration. Additionally, support for remote Continuous Compliance Engine calls has been implemented and is supported in 5.0.4 and above.
2. Continuous Compliance Engines should continue to be deployed to hosts dedicated to that function.
  - Possible exceptions to this would be when any virtualization needed is extremely low and unlikely to be heavily impacted by masking requirements.
3. The Masking Engine is disabled by default.
  - The Delphix Engine will continue to remain running (but unused) on a Masking-only VM.
4. The standard configuration for a dedicated Continuous Compliance Engine:
  - a. 8 vCPUs
  - b. 16GB RAM minimum, 32 GB RAM or more recommended.
  - c. 300 GB storage for the OS/system root disk is required for the OS (5.1.4 and greater).
  - d. 50 GB storage for the data disk must be added during the initial configuration via the Engine Setup wizard. (the engine will not complete its setup without a separate data disk).
  - e. If a bulk operation is used, allocate extra space equivalent to the size of all datasets (tables) that will be masked concurrently.

- i. As a rule of thumb: *Disk Space Required for Bulk* =  $((Total\ Database\ Size * .66) * .10)$  where *Raw data* =  $Total\ Database\ Size * .66$
- ii. 10% change is an estimate based on our experience for data we mask. Often it is lower but there are exceptions such as masking a data warehouse with a large fact table and a bunch of much smaller tables.
- iii. The VMDK for the engine OS is often stored on the same VMFS volume as the VM definition file (aka VMX). In that case, the VMFS volume must have sufficient space to hold the VMX Configuration, the VDMK for the system disk, and any VMWare logging.
- iv. Additional VMFS space for swap/paging is required if RAM reservations are not enabled. (The VM will not start if reservations are lacking and disk space is not available for swap)

### CPU utilization

1. One vCPU per concurrent masking job is considered a best practice.
2. Dependent on the algorithms used: Some are calculations such as ones using AES encryption and others are lookups and tend to do more I/O.

### Memory utilization

1. The Continuous Compliance Engine uses its memory to cache data. More memory will provide better performance. 1GB per masking job is considered a best practice.
2. Dependent on memory settings in the Masking Engine and JVMs. An increase in parallel workloads will require more memory. Data is either cached directly or using Kettle so the larger the lookups for algorithms the more memory required. This is the first thing to look at for performance issues.

### Network and I/O

Continuous Compliance leverages the Target DB server and VDB for most of the workload. This means the masking engine can be I/O bound waiting for the DB server. As long as the masking engine can read the data faster than it can process it this is not an issue. Slow networks with numerous hops between the DB server and the Masking server can cause performance problems. Co-locating the masking server with the DB server is recommended in these cases.

### Masking VDB tuning

1. Always start with the tuning recommendations for Target servers and VDBs first. If the VDB is not performing well, the performance of masking will suffer.
2. For Oracle, it is critical to select no archivelog mode and tune online redo log size at provision time.
3. For SQL Server, the VDB should be in SIMPLE recovery with an appropriate log file and TempDB sizes.

### Backup of a continuous compliance engine

1. Virtual machine backups are recommended for versions of software in which masking runs in its own VM – in other words, the masking VM is separate from the VM(s) where virtualization takes place.
  - a. If an engine is supporting both masking and virtualization, review data protection best practices.
  - b. Although XML exports of inventories and environments do exist, they are incomplete. Do not rely on them.
2. In-Place (not On-the-Fly) Masking is the primary use case.

The following recommendations apply to the Continuous Compliance Engine versions 5.0.2 and earlier:

1. Jobs vs. Streams:
  - a. If there are multiple tables to be masked concurrently, use multiple, separate jobs – one per table.
  - b. Avoid multiple streams due to internal limitations.

1. The default setting for streams is 20; set it to 1. This will force serialization (one table at a time) if the job contains multiple tables.

2. Use one update thread per job; this avoids block collisions/contention during the UPDATE phas.

 The default setting is 4; set it to 1.

- a. Identify ALL indexes, constraints, and triggers on columns being masked (and only on columns being masked).
  - b. Evaluate whether it is better to drop/mask/recreate for indexes, or disable/mask/re-enable for triggers and constraints – as compared to leaving in-place during masking. The best choice depends on the situation
3. For Oracle VDBs, use ROWID for SQL UPDATE of masked row value(s).
1. Edit the ruleset, select Edit All Logical Keys, enter ROWID as the logical key value; see [Managing Rule Sets](#). When a single, large, non-partitioned table must be masked by concurrent jobs (each masking a subset of the table) to shorten masking elapsed time, segregate jobs by database block/page to avoid contention and locking conflicts. In other words, each job masks a unique set of blocks; each block is masked exclusively by one job.
  2. If a single table is being masked by multiple, concurrent Jobs, and Indexes/constraints/triggers must be dropped/recreated or disabled/enabled, these must be performed OUTSIDE of masking Jobs.
  3. Pre-masking and post-masking steps must be created manually.
  4. Scheduling of pre-script and post-script jobs must be devised. Plan to scheduled/execute externally.

## Architecture best practices for source DB and OS settings

### Oracle

1. ARCHIVELOG must be enabled: `select log_mode from v$database.`
2. FORCE LOGGING should be enabled to ensure VDBs are not missing data. When NOLOGGING redo is applied during provision, the resulting VDB will be missing changes. Tables with NOLOGGING changes will throw corruption errors when scanned.
3. Block Change Tracking should be enabled to minimize snapsync time.
4. Consult the documentation for Oracle Standby sources.
5. If the database is encrypted with Oracle TDE (Transparent Data Encryption) plan your Delphix storage requirements with the expectation of minimal compression. Customer Observation: space usage for a TDE dSource copy was 92% (2.44 TB) of the source database size (2.67 TB). A typical Oracle dSource copy for a non-TDE database consumes 40% of the source database size.

### SQL server

1. FULL vs SIMPLE recovery mode trade-off.
2. The maximum size of an MSSQL database that can be linked is 256TB for Windows versions greater than 2003. The limit is 2TB for Windows 2003. (See [Linking a SQL Server dSource](#))

## Architecture best practices for target DB and OS settings

### Target database application settings

1. Oracle:
  - a. Provision with 3 x 5GB online redo logs (minimum) to avoid pause when transaction logs wraparound.
  - b. A provision in NOARCHIVELOG mode to reduce transaction log IO. Masking, Test, QA VDBs rarely need point-in-time rewind

- c. Always check initialization parameters inherited from a parent, remove any expensive or irrelevant parameters.
  - i. `DB_CACHE_SIZE`, `SGA_TARGET` : set based on the target system being compared to.
  - ii. `FILESYSTEMIO_OPTIONS` to `SETALL` . Any other setting inherited from the source is probably wrong.
  - iii. `DB_BLOCK_CHECKSUM`, `DB_BLOCK_CHECKING`, `DB_LOST_WRITE_PROTECT`, `DB_ULTRA_SAFE` : set to default values to minimize the impact.
  - iv. `PARALLEL_DEGREE_POLICY` to `AUTO` , `PARALLEL_MAX_SERVERS` default, `PARALLEL_EXECUTION_MESSAGE_SIZE` to 32768 (maximum): improve PQ performance.
  - v. `FAST_START_MTTR_TARGET` : drives steady write activity. Set based on the target system being compared to.
  - vi. Consider non-durable commits for Masking, Test, QA, UAT: set `COMMIT_WAIT = NOWAIT` , `COMMIT_LOGGING = BATCH`
- d. Use Oracle Direct NFS (dNFS) for 11.2.0.4+ (**unstable** on older releases):
  - i. Recommended documentation:
    - [Configuration Examples and Troubleshooting blog](#) from Helmut Hutzler
    - Sample oranfstab to leverage multiple network paths for Delphix VDB
  - ii. Set `DNFS_BATCH_SIZE` = 128 (default is 4096). This is a good starting point and sufficient for most workloads.
  - iii. Tune TCP stack: set `tcp_adv_win_scale` = 2 due to workaround hard-coded Oracle dNFS TCP buffer size.
  - iv. Check Alert Log, `V$DNFS_SERVERS`, `V$DNFS_FILES`, `V$DNFS_STATS` to verify proper working (sample [here](#)).
- e. Create AWR snapshots around a reference customer workload, generate an AWR report.
  - i. AWR snap before/after workload: `SQL> exec DBMS_WORKLOAD_REPOSITORY.CREATE_SNAPSHOT();`
  - ii. AWR report between the snaps: `SQL> @?/rdbms/admin/awrrpte`
- f. Generate ASH report to diagnose bottlenecks while a workload is running.
  - `SQL> @?/rdbms/admin/ashrpt`
- g. Run synthetic benchmark `sc-workload`.
- h. Where `db file scattered read` (multiblock cached read) latency is high consult this Support KB: [How to Mitigate Multi-Block Read Performance on Oracle 10g](#)
- i. Improve distributed query performance by modifying dblinks to use local IPs instead of SCAN IPs.
- j. NFS recommended mount options for Oracle RAC/SI: [Oracle Support Note 359515.1](#).

## Target Host OS Settings

1. Existing documentation on Target OS practices: [Target Host OS and Database Configuration Options](#)
2. HP-UX 11.31+
  - [Async NFS Direct I/O](#): HP-UX requires Oracle `disk_asynch_io` turned off for filesystems
3. IBM AIX:
  - a. Consult IBM documentation on AIX TCP Tuning
  - b. [AIX TCP Tuning Prezo](#)
4. Windows:

- a. Anti-virus programs can impact both performance and operation. Delphix recommends anti-virus scanning exclude folders where Delphix files are maintained, in addition to the normal exclusions put in place for MSSQL operation.
- b. Delphix Connector (aka DX Connector):
  - i. Plan 3-5GB for the Delphix Connector installation.
  - ii. Windows does not yet have ssh, so Delphix developed the "DX Connector for Windows target host communication.
  - iii. The connector must be installed on all Target Windows hosts.
  - iv. The connector supports two modes – v1 and v2 both use the same application binaries.
  - v. The connector v1 process is used to bootstrap the v2 process on a target. This opens a DSP session back to the Delphix Engine (The same thing is done via SSH on U\*nix Targets)
  - vi. v2 mode is required to enable SQL hooks
  - vii. The connector can always be downloaded from a local Delphix Engine at: `http://<delphix_engine>/connector/DelphixConnectorInstaller.msi`.
  - viii. The connector is backward compatible, so it is not always necessary to upgrade it during a Delphix upgrade.
- c. iSCSI connections:
  - i. Read the following for general awareness of iSCSI limits
  - ii. In addition to the hard limits on iSCSI connections, consideration must be given to the RAM, CPU, and Network to provide sufficient resources for the load on any Target or Staging host.
  - iii. To increase the iSCSI timeout on both Target and Staging hosts.
  - iv. In certain circumstances, it's possible that iSCSI startup will not complete before the SQL Service attempts to start a database. In such circumstances, it can be helpful to ensure the SQL service depends on the iSCSI service.
    - Example: `c:\> sc config "MSSQLServer" depend="Microsoft iSCSI Initiator Service"`
  - v. **Note** that any changes to iSCSI are system-wide and could potentially impact other applications also leveraging that feature.
- d. [Enable Receive Side Scaling \(RSS\)](#) on each network interface that Delphix will be connecting to.

## Architecture best practices for Staging Targets

This host is called a "staging target" because it has much in common with other targets, such as the remote storage mount to the Delphix Virtualization Engine. Because it leverages remote storage over the network, the staging target only needs enough disk capacity for the OS, database application, and any relevant logs or tools. A staging target is a requirement on all platforms that Delphix supports except Oracle, but you can also use it for Oracle to replay logs leveraging [validated sync](#).

### Memory and CPU

1. 32 GB RAM minimum
2. 4 vCPU minimum

### General guidance for staging servers (Multi-platform)

1. Delphix recommends dedicated Staging servers for role/architecture separation. However, any Target server can be used as Staging.
2. In cases where the same server is used as both Staging and Target, we strongly recommend a dedicated instance/install for staging to avoid confusion.
3. Delphix recommends at least one Staging server per Delphix Engine to avoid the possibility of a single point of failure across multiple engines.
4. If a staging server is shared among multiple Delphix Engines, please ensure that a dedicated SQL Server Instance is created for each Delphix Engine.
5. Configuration / performance factors:

- a. Transaction log generation rate.
- b. Number of VDBs.

 Precise guidance on these items has not yet been defined. In general, if there is a heavy log generation rate and few VDBs, the ideal recommendation is to have at least 1 Staging Target per Delphix Engine.

## Disk / Local storage

1. The only local storage needed is for the OS and application with default databases.
2. Storage for a staging database is provided from the Delphix Engine, which is mounted over the network similar to any Target host (NFS/iSCSI).
3. If the customer has a standard DB server build, their standard storage sizing is probably fine.
4. If a recommendation is still needed, suggest 30GB for OS and application and any tools needed.

## Network requirements

1. The Staging Target engages in network data transfers between Staging and the Source backup shared location as well as between Staging and the Delphix Engine.
2. The Staging Target is also a Target server, and as such should have < 1ms latency to the Delphix Engine (and low latency to the Source backup, when possible).
3. If the change rate on the Source database(s) is > 1 Gb/sec, the recommended network bandwidth to support network transfers is 10 Gb/sec.
4. In cases where only 1 Gb/sec network bandwidth is available, segregation of each network is recommended to reduce network contention.
5. Ensure that the virtual NIC is using the standard vmxnet3 adapter and not Intel for VMWare based clients. Logical IO errors have been reported while using Intel instead of vmxnet3 adapter.

## Windows and MSSQL Specific

1. An MSSQL Server Instance used for Staging should not be clustered.
2. Staging should not be hosted on Windows 2003 - extended support ended July 14, 2015. It is also the first Windows version with iSCSI support and is not ideal.
3. The SQL Server Instances hosted on the Staging Target should have a Maximum Memory set. Also ensure that at all times, at least 10% of total memory is available for OS operations.
4. Only system databases (Master/MSDB/Temp/MSDB) are kept on local storage. All other data is read/written to the Delphix Engine.
5. Windows iSCSI configuration and limits for v2p, target, and staging hosts.
6. [Ensure that Receive Side Scaling \(RSS\)](#) is enabled on every network interface that Delphix will be connecting to.

## Best practices for hypervisor host and VM guest

### Hypervisor

1. ESXi 6.x or 7.0 is recommended. ESXi 5.5 or earlier is no longer supported.
2. HyperThreading (HT) for Intel®-based servers (no HT on AMD CPUs).
  - a. Disable HT in BIOS, on the ESXi Host, **and** disable [HT sharing](#) on the Delphix VM for consistency. This is our best practice, disable at all levels.  
Any other combination may result in a non-deterministic performance.
  - b. When HT cannot be turned off for both the Host and Delphix VM, it should be turned on at all levels, not run in a "mixed-mode".
    - i. HT disablement at a guest level only can result in non-deterministic performance.
    - ii. A dedicated ESXi host, cluster or DRA is recommended where consistent VDB performance is paramount.
  - c. VM migration to a new host (e.g. VMware HA or vMotion) can create mismatched HT settings.
3. ESXi overhead (resources required for hypervisor cannot be reserved, they must be left unallocated).
  - a. Memory Overhead - 10% of available RAM must not be allocated to guest VMs.
    - *Example: 256GB RAM, allocate 230GB to Delphix VM, leave 26GB for ESX*
  - b. CPU Overhead - At least 2 cores (ideally 4) must not be allocated to guest VMs.
    - *Example: If 16 physical cores are available, allocate 12 to the virtual machines, leaving 4 for the hypervisor*
    - **Why 4?** Certain hypervisor functions require precedence over any virtualized system. If a hypervisor needs more CPU than the amount currently available, it can de-schedule all other virtual processes to ensure adequate CPU resources for the hypervisor. Ensuring the hypervisor will not have to de-schedule any running virtual processes (worlds) by setting aside and not over-subscribing CPUs for virtual functions will leave them available for hypervisor use.
  - c. Even if the Delphix VM is the only VM on a host, the hypervisor is still active and essential; and still needs resources.
4. BIOS Power Management should be set to High Performance where ESXi controls power management.
  - a. It can be impacted by [VMware KB 1018206](#) - poor VM application performance caused by power management settings.
  - b. Ensure that all BIOS managed C-States other than C0 are disabled if power management is hardware controlled.
  - c. Ensure that all ACPI sleep states above S0 are disabled in the BIOS.
  - d. Examples for popular server lines from Cisco, HP, Dell below. *Specific models will vary, use the appropriate spec sheet.*
    - i. UCS: disable the Processor Power States, disable Power Technology, set Energy Performance to "Performance"
    - ii. HP Proliant: set HP Power Regulator to HP "Static High Performance" mode
    - iii. Dell: set BIOS System Profile to "Performance Optimized" mode
5. VMware HA can be enabled; VMware DRS is generally disabled.
6. Blade/Rack Server Firmware and ESXi Drivers should be updated to the latest versions.
7. For Intel®-based servers with E5-2600 v2 processors.
8. Two typical server configurations:
  - a. Blade Farm
  - b. Rack Server

Hyper-Converged configurations are possible for high performance.

## Virtual machine guest

1. For VM machine settings, see [Virtual machine requirements for VMware platform](#)
2. VMWare Guest Specifications:
  - a. Minimum: 8 vCPU x 64 GB  
Small: 8 vCPU x 128GB  
Medium: 16 vCPU x 256 GB  
Large: 24 vCPU x 512 GB
  - b. Reserve 100% of RAM and CPU:
    - If the ESX host is dedicated to Delphix, CPU and RAM reservations are advised but not necessary, however, swap space will be required on the hypervisor to compensate for the lack of reserved RAM.
  - c. [Hyperthreading](#) - See the ESX host section at the top. Disable HT Sharing on VM, disable HT on ESX Host.
3. Assign single-core sockets for vCPUs in all cases. If there is a compelling reason to use multi-core vCPUs, reference the following article from VMware which describes matching virtual multi-core sockets to the hardware ESX is running on.  
[VMware article on CoresPerSocket](#)  
Example: *ESXi Host has 2 socket x 18 core Intel Xeon, Delphix Engine wants 16 vCPU.*  
Configure Delphix VM with 2 Virtual Sockets, 8 Cores Per Socket to utilize hardware architecture.
4. Avoid placing other extremely active VMs on the same ESX host.
5. Monitoring - vSphere Threshold Alerts for CPU, Network, Memory, Capacity.
6. To set the number of vCPUs per virtual machine via the vSphere client, please see "[Virtual CPU Configuration](#)" in the Administration guide:  
[ESXi 6.0](#)
  - a. [Delphix VM CPU utilization](#) - Delphix KB article on what makes Delphix VMs similar to other resource-intensive applications
  - b. [Exchange on VMware best practices](#) - VMworld 2013 session
  - c. [ESXTOP reference, blog](#)
7. Ensure that the latest available VMware drivers and firmware versions are installed for HBAs, NICs and any other hardware components configured on the Delphix virtual machine. This is a critical step that can have a massive impact on the performance and robustness of our solution.

## Best practices hypervisor host and VM guest ESX FAQ

### Frequently asked questions

Why does Delphix require a minimum of 8 vCPUs and recommend 128 GB per 8 vCPUs?

8 vCPUs are not only a standard licensing block, but they are also key to meeting our 10Gbps single-engine throughput potential and help to sustain low latency for VDBs.

As with CPU, cache memory is required to drive peak loads on the Delphix Engine. More memory allows for more blocks to be read from the cache rather than going to less performant disks. Delphix stores cached data in a compressed format and only keeps a single copy of unique blocks in memory. These features give read performance across multiple VDBs provisioned from a single source dramatic improvements in speed, scalability and memory utilization.

Why does Delphix request reservations for CPU and memory?

Delphix performance can be greatly impacted there is contention over CPU or RAM. Reservations allow the engine to explicitly control those resources and avoids the possibility of contention with other VMs, even when resources are overcommitted.

Why does Delphix request Hyper-Threading (HT) be disabled?

Hyper-Threading can have a positive impact on many, but not all applications. Delphix has a different execution profile that does not benefit from Hyper-Threading. Factors such as significant memory bandwidth requirements and a high level of parallelism which requires a high number of shared locks mean that HT and Delphix do not generally work well together.

Why does Delphix request 4 controllers, and why must the storage be identical between them?

To provide optimal storage performance, you must spread data equally over the maximum (4) virtual SCSI controllers. To provide consistent performance between each of the four controllers, you need to ensure storage is identical between them.

Why must virtual disks (VMDKs) be thick provisioned and eager-zeroed?

Thick provisioning and eager zero ensure performance is top-notch from the start with no hiccups from expanding virtual resources.

Why is 20% free space required?

While the ZFS file system has a lot of features leveraged by Delphix, it loses efficiency as space decreases. 20% is the minimum that must be available for best performance.

Why does Delphix request you reserve CPU and RAM for Hypervisor overhead?

Based on VMWare's resource management guide and our own experiences with high IO throughput. Note there is no specific mechanism to assign resources to the hypervisor, the only way to preserve overhead is by not allocating resources to guests.

Why does Delphix generally want VMWare HA enabled, but DRS disabled?

VMware HA (High Availability) addresses outages that occur when a physical host goes down or is completely offline, by migrating the guest(s) to another physical host and restarting them. There is no real downside, it simply brings unavailable servers back online.

VMware DRS (Distributed Resource Scheduler) is for load balancing host resources in a cluster. Because of high IO and best practices configuration for optimal performance, our engine is typically not a good candidate for relocation.

Why does Delphix request you set power management to High-Performance Mode?

This will ensure power management will never impact performance by entering into a lower power state (also known as c-state).

## Best practices for network configuration

1. For more information about network configuration refer to [Network performance configuration options](#)
2. Delphix engine <====> Target Host: *Implement standard requirements for optimal NFS/iSCSI performance:*
  - a. Optimal physical network topology:
    - Low latency: < 1ms for 8K packets.
    - Network adjacency: minimize network hops, co-locate in the same blade enclosure, co-locate on the same physical host.
    - Eliminate all Layer 3+ devices - firewalls, IDS, packet filters (Deep Packet Inspection - DPI).
    - Multiple switches can add latency and fragmentation and reordering issues will add significant latency.
  - b. Optimal throughput:
    - 10GbE physical uplinks or higher.
    - Jumbo frames (typically MTU 9000) improves network efficiency for 8K packets: lower CPU, lower latency, greater throughput.
    - All devices end-to-end *must* be configured for the larger frame size including switches, routers, fabric interconnects, hypervisors and servers.
    - Traffic between two VMs on the same host is limited to ~16Gbps when leveraging built-in virtual networking.
  - c. Optimal logical flow:
    - Disable QoS throttles limiting network utilization below line rate (e.g. HP Virtual Connect FlexFabric).
    - Consider a dedicated VLAN (with jumbo frames) for NFS/iSCSI traffic.
      - [VMware KB-configuring iSCSI port binding with multiple NICs in one vSwitch for VMware ESXi 6.0.x \(2045040\)](#)
      - [VMware KB-considerations for using software iSCSI port binding in ESX/ESXi \(2038869\)](#)
  - d. NIC Teaming (at ESX layer) of multiple physical uplinks can provide additional throughput for higher workloads.
    - i. Examples: 4 x 1Gb NICs support up to 400 MBPS IO, 2 x 10Gb NICs support up to 2 GBPS IO.
    - ii. [VMware KB-1004088](#) has NIC teaming recommendations, including `route-based-on-IP-hash` policy.
    - iii. [VMware KB-1001938](#) has host requirements for physical link aggregation (LACP, EtherChannel).
    - iv. [VMware KB-1007371](#), [popular blog post](#) details problems with NIC selection using `dest-IP hash`.
  - e. **Jumbo frames check via ping**

```
Delphix Engine
$ ping -D -s [Target_IP] 8000
"ICMP Fragmentation needed and DF set from gateway" indicates MTU < 8028

Linux
$ ping -M do -s 8000 [Delphix_Engine_IP]
"Frag needed and DF set (mtu = xxxx)" indicates MTU < 8028

MacOS
ping -D -s 8000 [Delphix_Engine_IP]
```

Note: "`sudo sysctl -w net.inet.raw.maxdgram=16384`" will increase the max ICMP datagram size on Mac, allowing you to use `-s 9000` on Mac0

Windows

`ping -f -l 8000 [Delphix_Engine_IP]`

<http://www.mylesgray.com/hardware/test-jumbo-frames-working/>

Copy

- f. Measure network bandwidth and latency:
  - i. Latency in both directions should be < 1ms for an 8KB payload.
  - ii. Network Hops should be minimized: `tracert` (Windows) / `tracert` (Windows).
  - iii. Throughput in both directions: 50-100 MB/s on 1 GbE, 500-1000 MB/s on 10 GbE physical link.
  - iv. Always use the CLI when possible.
- g. NIC should use Auto-negotiate on Ethernet with a minimum of 1000Mbps.
  - Hard setting speed/duplex will limit network throughput below the line rate.
3. **Delphix <====> Staging server**(SQL Server, Sybase):  
Measure latency, bandwidth for transaction log restore performance
4. **Source <====> Delphix:**  
Measure latency, bandwidth to explain snapsync performance
5. **ESX host <====> ESX host**(ESX Cluster):
  - a. This is because the entire memory footprint of the Delphix VM (more precisely, the entire address space of the ESX processes that comprise the VM) must be copied to the receiving ESX host, along with all changes to that address space as they happen. Our ZFS cache comprises the bulk of that memory and changes as I/O occurs, and that rate of change is governed by the network bandwidth available to the Delphix Engine.
  - b. Attempting to live vMotion a DE with a 10Gb NIC over a 1Gb vMotion network is thus likely to fail.

## Best practices network FAQ

### Frequently asked questions

Why does Delphix request 10GE Ethernet?

As a matter of physics and standards - 10 gigabit (Gb) Ethernet can sustain approximately 1 gigabyte (GB) per second of throughput. With all our best practices applied, a Delphix Engine can achieve very close to that line speed, allowing for optimal load, engine, and license utilization. Lower network speeds may be acceptable for low loads, while in some environments NIC teaming (e.g. LACP) may be required for top speeds.

Why does Delphix require < 1ms latency to TARGET servers and < 50ms to SOURCE servers?

Delphix leverages NFS and iSCSI (depending on platform) for live TARGET DB mounting over the network, so it's imperative that latency is as low as possible. Data coming from SOURCE servers is not generally as time-sensitive, so you need a minimum latency of < 50ms to ensure operational integrity.

Why does Delphix request Jumbo Frames?

Jumbo frames increase the Ethernet maximum transmission unit (MTU) from the default 1500 bytes to 9000 bytes. This has several effects such as decreasing CPU cycles by transferring fewer packets and increasing the engine throughput. You will find jumbo frames have a 10-20% real-world impact and are required (along with all other best practices) to handle peak loads of 800 - 1000MB/s on an 8 vCPU engine with a 10Gb network.

How does Delphix avoid communication impact with non-jumbo frame hosts when Jumbo Frames are enabled on the Delphix Host?

[Path MTU Discovery](#) is the mechanism by which two hosts agree on the MTU leveraged for communication between them. This mechanism will ensure communication between both standard and Jumbo Frame enabled hosts works as expected.

When does Delphix recommend NIC teaming?

The Delphix Engine is capable of high throughput, but not every enterprise has sufficient network bandwidth to support it. Teaming is a less expensive way of increasing the bandwidth when compared to new hardware.

Why does Delphix recommend logical and physical and co-location?

The Delphix Engine leverages network connections extensively, so optimizing the latency whenever possible is very important - sometimes critical.

## Best practices for Delphix engine data protection

The following are recommended best practices for data protection in the Delphix Engine.

1. For protection against physical host failure - leverage VMware HA.
2. For protection against storage failure - leverage Delphix replication.
3. For protection against administrative error - leverage storage snapshots.
4. For protection against site failure - leverage Delphix replication and/or Delphix Live Archive.
5. Infrastructure Backup of the Delphix VM:  
Must take a consistent group snapshot of all Delphix VM storage (system disk, VM configuration, database VMDK/RDMs)  
RTO, RPO are inferior compared to Delphix Replication. The granularity of restore is at the VM level: **all-or-nothing**.
  - a. Virtual machine backup: Create VM snapshot, backup (proxy server), remove the snapshot.  
Products use VMware APIs: NBU for VMware, TSM, NetWorker  
Limited to < 2TB because of time to backup, impact on running VM
  - b. Storage array backup: Take a consistent storage snapshot, replicate to tape/VTL media server, remove the snapshot.  
Products include Hitachi Shadow Copy, EMC SnapCopy, HP Business/Snap Copy.

## Best practices Delphix engine data protection FAQ

### Frequently Asked Questions

Why does Delphix recommend SAN snapshots or Delphix replication for backup?

There are a few possible methods for data protection of the Delphix Engine. Those methods are SAN snapshots, Delphix replication, and virtual machine snapshots (for very small engines only). Because the Delphix Engine is itself a backup of source environments, many customers simply plan to rebuild in the event of a disaster.

What is the DXToolkit, and how can it help?

The professional services team has created a Perl-based “DXToolkit” which can help export and import certain configuration data over web services. This toolkit can be leveraged to assist with would normally be a manual re-install outside of the above methods.

For further detail around data protection, please speak with your Delphix contact.

Can I use a VMware-based backup solution such as VEEAM to backup my Delphix Engine?

Yes, VMWare backup solutions are useful for backing up guest VMs. However, Delphix suggests that you only use this approach for Delphix Engines which have a smaller storage footprint (perhaps < 2 TB) and are less active.

Running this type of backup puts a load on the environment, which might adversely impact Delphix VM performance.

Can I use a VMware snapshot for backing up Delphix for a small window – for example, during an engine upgrade?

Yes. However, even though snapshots are instantaneous, they track changes separately from the base disks and can grow to consume as much space as the original.

 Upgrades, in particular, can change substantial amounts of data. If you lose physical disks, snapshots are useless because it needs them to make up the current state of VM. A Delphix Engine is often allocated multiple terabytes of storage and is often very busy due to load aggregation from virtual databases on multiple target servers, so this approach may be challenging. Snapshots cannot detect storage corruption.

Can I use a Storage snapshot solution to protect Delphix against Storage and Delphix corruption?

Yes. However, please note that the caveats which apply to VMWare snapshots will also apply here.

 A specific concern related to storage layer snapshots is that you must create a consistency group that contains both the OS and Data disks.

Can I use RMAN to backup my VDBs just like a Physical database to provide extra protection?

You can backup Delphix VDBs using Oracle RMAN tools, but the recovery database would first require re-hydration of that VDB, which might take up equivalent production storage space.

Furthermore, that re-hydrated database needs to be brought into the Delphix framework as a dSource, after which you can provision a VDB to complete recovery. The whole process might take hours or days to recover.

The best approach is to use the VDB Snapshot capability to backup VDB frequently and then leverage Delphix Replication capability to protect underlying Delphix storage, which holds that VDB snapshot.

## Best Practices for source DB and OS settings

### Best practices

#### Oracle

1. ARCHIVELOG must be enabled: `select log_mode from v$database.`
2. FORCE LOGGING should be enabled to ensure VDBs are not missing data. When NOLOGGING redo is applied during provision, the resulting VDB will be missing changes. Tables with NOLOGGING changes will throw corruption errors when scanned.
3. Block Change Tracking should be enabled to minimize snapsync time.
4. Consult the documentation for Oracle Standby sources.
5. If the database is encrypted with Oracle TDE (Transparent Data Encryption) plan your Delphix storage requirements with the expectation of minimal compression. Customer Observation: space usage for a TDE dSource copy was 92% (2.44 TB) of the source database size (2.67 TB). A typical Oracle dSource copy for a non-TDE database consumes 40% of the source database size.

#### SQL server

1. If using a FULL recovery model, configure your dSource to stay synchronized using Transaction Log backups. This will usually allow the dSource to stay in sync using much less network and disk IO than Full or Differential backups.
2. Ensure that the number of Virtual Log Files (VLFs) in the Source database is appropriate. Databases with hundreds or thousands of VLFs will experience slower provisioning times as SQL Server must do more work during recovery. The blog post [A Busy/Accidental DBA's Guide to Managing VLFs](#) has helpful information here.
3. Review index maintenance and defragmentation operations on your Source database, to ensure that they are not running more often than necessary. Many maintenance operations are logged, and can result in extremely large log backups without much benefit to the database server. See [Stop Worrying About SQL Server Fragmentation](#).
4. If configuring a dSource to use Full or Differential backups, ensure that Source database backups do not run at the same time as database maintenance or large batch operations. This can significantly increase the amount of time required to perform database recovery and will slow down the provisioning of VDBs.
5. For best compatibility with the Delphix Engine, avoid taking log backups more frequently than every 10 minutes. The validated sync process requires time to detect and validate log backups before they can be applied to a dSource, and extremely high-frequency log backups can make it difficult for a dSource to stay in sync.
6. If you are using SQL Authentication for database logins, and you want Source database users to be mapped to database logins when provisioning VDBs, ensure that the SID of your database logins is the same between your Source and Target environments (the passwords can be different). For more details, see the [Correcting Orphaned SQL Server Database Users \(KBA1111\)](#) KB article.
7. To maximize dSource performance, ensure that backups are being taken to a disk drive or network location that can be accessed by the Staging Server at high speed.

## Best practices for target DB and OS settings

### Target database application settings

1. Oracle:
  - a. Provision with 3 x 5GB online redo logs (minimum) to avoid pause when transaction logs wraparound.
  - b. Provision in NOARCHIVELOG mode to reduce transaction log IO. Masking, Test, QA VDBs rarely need point-in-time rewind
  - c. Always check initialization parameters inherited from parent, remove any expensive or irrelevant parameters.
    - i. `DB_CACHE_SIZE`, `SGA_TARGET` : set based on target system being compared to.
    - ii. `FILESYSTEMIO_OPTIONS` to `SETALL` . Any other setting inherited from source is probably wrong.
    - iii. `DB_BLOCK_CHECKSUM`, `DB_BLOCK_CHECKING`, `DB_LOST_WRITE_PROTECT`, `DB_ULTRA_SAFE` : set to default values to minimize impact.
    - iv. `PARALLEL_DEGREE_POLICY` to `AUTO` , `PARALLEL_MAX_SERVERS` default, `PARALLEL_EXECUTION_MESSAGE_SIZE` to 32768 (maximum): improve PQ performance.
    - v. `FAST_START_MTTR_TARGET` : drives steady write activity. Set based on target system being compared to.
    - vi. Consider non-durable commits for Masking, Test, QA, UAT: set `COMMIT_WAIT = NOWAIT`, `COMMIT_LOGGING = BATCH`
  - d. Use Oracle Direct NFS (dNFS) for 11.2.0.4+ (**unstable** on older releases):
    - i. Recommended documentation:
      - [Oracle direct NFS configuration](#)
      - [Configuration examples and troubleshooting blog](#) from Helmut Hutzler
      - Sample oranfstab to leverage multiple network paths for Delphix VDB
    - ii. Set `DNFS_BATCH_SIZE = 128` (default is 4096). This is a good starting point and sufficient for most workloads.
    - iii. Tune TCP stack: set `tcp_adv_win_scale = 2` due to workaround hard-coded Oracle dNFS TCP buffer size.
    - iv. Check Alert Log, `V$DNFS_SERVERS`, `V$DNFS_FILES`, `V$DNFS_STATS` to verify proper working (sample [here](#)).
  - e. Create AWR snapshots around a reference customer workload, generate an AWR report.
    - i. AWR snap before/after workload: `SQL> exec DBMS_WORKLOAD_REPOSITORY.CREATE_SNAPSHOT();`
    - ii. AWR report between the snaps: `SQL> @?/rdbms/admin/awrrpte`
  - f. Generate ASH report to diagnose bottlenecks while a workload is running.
    - `SQL> @?/rdbms/admin/ashrpt`
  - g. Run synthetic benchmark `sc-workload`.
  - h. Where `db file scattered read` (multiblock cached read) latency is high consult this Support KB: [How to mitigate multi-block read performance on Oracle 10g](#)
  - i. Improve distributed query performance by modifying dblinks to use local IPs instead of SCAN IPs.

- j. NFS recommended mount options for Oracle RAC/SI: [Oracle support note 359515.1](#)

## Target Host OS Settings

1. Existing documentation on Target OS practices: [Target host configuration options for improved performance](#)
2. HP-UX 11.31+
  - [Async NFS direct I/O](#): HP-UX requires Oracle `disk_asynch_io` turned off for filesystems
3. IBM AIX:
  - a. Consult IBM documentation on AIX TCP Tuning
  - b. [AIX TCP tuning prezo](#)
4. Windows:
  - a. Anti-virus programs can impact both performance and operation. Delphix recommends anti-virus scanning exclude folders where Delphix files are maintained, in addition to the normal exclusions put in place for MSSQL operation.
  - b. Delphix Connector (aka DX Connector):
    - i. Plan 3-5GB for the Delphix Connector installation.
    - ii. Windows does not yet have ssh, so Delphix developed the "DX Connector for Windows target host communication.
    - iii. The connector must be installed on all Target Windows hosts.
    - iv. The connector supports two modes – v1 and v2 both use the same application binaries.
    - v. The connector v1 process is used to bootstrap the v2 process on a target. This opens a DSP session back to the Delphix Engine (The same thing is done via SSH on U\*nix Targets)
    - vi. v2 mode is required to enable SQL hooks
    - vii. The connector can always be downloaded from a local Delphix Engine at: `http://<delphix_engine>/connector/DelphixConnectorInstaller.exe`.
    - viii. The connector is backwards compatible, so it is not always necessary to upgrade it during a Delphix upgrade.
  - c. iSCSI connections:
    - i. Read the following for general awareness of iSCSI limits
    - ii. In addition to the hard limits on iSCSI connections, consideration must be given to the RAM, CPU and Network to provide sufficient resources for the load on any Target or Staging host.
    - iii. To increase the iSCSI timeout on both Target and Staging hosts.
    - iv. In certain circumstances it's possible that iSCSI startup will not complete before the SQL Service attempts to start a database. In such circumstances, it can be helpful to ensure the SQL service depends on the iSCSI service.
      - Example: `c:\> sc config "MSSQLServer" depend="Microsoft iSCSI Initiator Service"`
    - v. **Note** that any changes to iSCSI are system-wide and could potentially impact other applications also leveraging that feature.
  - d. [Enable receive side scaling \(RSS\)](#) on each network interface that Delphix will be connecting to.

## Receive side scaling (RSS) for windows staging target and targets

Enabling Receive Side Scaling (RSS) on a Windows Target and Staging Target can have a significant improvement in the overall IO throughput to the Delphix Engine and is a best practice. RSS enables network adapters to distribute the kernel-mode network processing load across multiple processor cores in multi-core computers. The distribution of this processing makes it possible to support higher network traffic loads than would be possible if only a single core were to be used.

More information on RSS can be found [here](#).

**⚠** Enabling RSS on the network interface will force the network service to restart and will cause a momentary loss of connectivity on that network interface.

**i** Because hyper-threaded CPUs on the same core processor share the same execution engine, the effect is not the same as having multiple core processors. For this reason, RSS does not use hyper-threaded processors.

### Steps to implement RSS on windows

1. From Server Manager/Local Server/Network Connections select the NIC that Delphix will be connecting to.

2. Select Properties and then Configure.

3. From the Property menu on the left, select Receive Side Scaling and select 'OK' to close each of the open windows.

## Best practices for staging targets

This host is called a "staging target" because it has much in common with other targets, such as the remote storage mount to the Continuous Data Engine. Because it leverages remote storage over the network, the staging target only needs enough disk capacity for the OS, database application, and any relevant logs or tools. A staging target is a requirement on all platforms that Delphix supports except Oracle, but you can also use it for Oracle to replay logs leveraging [validated sync](#).

### Memory and CPU

1. 32 GB RAM minimum
2. 4 vCPU minimum

### General guidance for staging servers (Multi-platform)

1. Delphix recommends dedicated Staging servers for role/architecture separation. However, any Target server can be used as Staging.
2. In cases where the same server is used as both Staging and Target, we strongly recommend a dedicated instance/install for staging to avoid confusion.
3. Delphix recommends at least one Staging server per Delphix Engine to avoid the possibility of a single point of failure across multiple engines.
4. If a staging server is shared among multiple Delphix Engines, please ensure that a dedicated SQL Server Instance is created for each Delphix Engine.
5. Configuration / performance factors:
  - a. Transaction log generation rate.
  - b. Number of VDBs.

 Precise guidance on these items has not yet been defined. In general, if there is a heavy log generation rate and few VDBs, the ideal recommendation is to have at least 1 Staging Target per Delphix Engine.

### Disk / local storage

1. The only local storage needed is for the OS and application with default databases.
2. Storage for a staging database is provided from the Delphix Engine, which is mounted over the network similar to any Target host (NFS/iSCSI).
3. If the customer has a standard DB server build, their standard storage sizing is probably fine.
4. If a recommendation is still needed, suggest 30GB for OS and application and any tools needed.

### Network requirements

1. The Staging Target engages in network data transfers between Staging and the Source backup shared location as well as between Staging and the Delphix Engine.
2. The Staging Target is also a Target server, and as such should have < 1ms latency to the Delphix Engine (and low latency to the Source backup, when possible).
3. If the change rate on the Source database(s) is > 1 Gb/sec, the recommended network bandwidth to support network transfers is 10 Gb/sec.
4. In cases where only 1 Gb/sec network bandwidth is available, segregation of each network is recommended to reduce network contention.
5. Ensure that the virtual NIC is using the standard vmxnet3 adapter and not Intel for VMWare based clients. Logical IO errors have been reported while using Intel instead of vmxnet3 adapter.

## Windows and MSSQL specific

1. An MSSQL Server Instance used for Staging should not be clustered.
2. Staging should not be hosted on Windows 2003 - extended support ended July 14, 2015. It is also the first Windows version with iSCSI support and is not ideal.
3. The SQL Server Instances hosted on the Staging Target should have a Maximum Memory set. Also ensure that at all times, at least 10% of total memory is available for OS operations.
4. Only system databases (Master/MSDB/Temp/MSDB) are kept on local storage. All other data is read/written to the Delphix Engine.
5. Windows iSCSI configuration and limits for v2p, target and staging hosts.
6. [Ensure that Receive Side Scaling \(RSS\)](#) is enabled on every network interface that Delphix will be connecting to.

Delphix Engine controls the number of concurrent restore operations that can run on a staging environment by the validated sync workers, which means we throttle the number of restore operations done by validated sync workers running for different staging databases on the staging environment, with five executing at a time and others waiting for their turn as per First Come First Serve scheduling. This is done to improve overall system performance by reducing resource contention, disk I/O, and network traffic. Also, note that this limit is per Delphix Engine which is connecting to the staging environment.

Following are the limiting factors which will come into play when looking at the performance of staging databases on a staging environment when a validated sync worker runs to keep up with the production databases:

- Backup generation frequency: With higher backup frequency, increased restore time will be seen as the pre-provisioning worker will keep ingesting previous backups while new backups are being generated.
- Staging database count: When multiple staging databases are hosted on the same server, the backup ingestion load on the staging host will increase. Additionally, if the frequency of backups is high, there will be a greater number of candidates (pre-provisioning workers) waiting in the queue.
- Number of VDB hosted on the server
- Multiple Delphix Engines connecting to the same staging environment will increase the number of parallel restore operations running on the staging environment and contribute to the performance.

Below are the troubleshooting steps for improving performance:

- Have dedicated Staging servers for role/architecture separation from VDB
- Add CPU/Memory
- Decrease backup frequency
- Introduce dedicated networks

Sharing an example of performance in a given setup for reference purposes.

 **Note**  
The below findings are from a non-production setup

### Environment details

- Staging Host: 64 GB Memory, 8 vCPUs, ESXi version: 7.0.3
- Backup File Size: 200MB
- User for linking: Database user

### Setup notes:

- No other operations were executed on the Delphix Engine other than pre-provisioning worker running.
- No virtual database existed on the staging host.
- The source servers and the Delphix Engine are all on the same on-prem data center.

- Only one Delphix Engine was connecting to the staging host.

### Performance Scenario 1

For a staging host with the above configuration supporting 50 staging databases on a single database instance, and with every dSource having a backup at the 15-minute interval, the time taken to restore these transaction logs stay under 13 minutes (< 750 seconds) on average and hence the staging databases keep up with the backups.

### Performance Scenario 2

The same setup could support frequent backups, that is every 10 min, but required the staging databases to be reduced. For example, 40 staging databases on a single database instance could support backups every 10 minutes without causing any lag.

## Best practices for storage

1. Configuration:
  - a. Virtual Disks (VMDK) with spinning or tiered media must be thick provisioned + lazy zeroed.
    - For storage which is 100% SSD/EFD/Flash-based, continue to thick provision, however, eager zero is not necessary.
  - b. VMDKs may be homed on VMFS or RDM storage, however, VMFS is much more common and generally preferred.
  - c. Regardless of VMFS/RDM selection, physical LUNs must have uniform characteristics (RAID, spindle count, tier) and should be thin provisioned to save time.
  - d. Storage allocated must be identical between each vSCSI controller.
  - e. The supported maximum of four virtual SCSI controllers (PVSCSI (default) or LSI Logic Parallel) must be enabled. A mix of different types of SCSI controllers is not supported within the engine.
  - f. Virtual Disks must be evenly distributed across the 4 virtual SCSI controllers. For example, 8 virtual disks should be configured as 2 disks per controller: SCSI (0:0), SCSI (0:1), SCSI (1:0), SCSI (1:1), SCSI (2:0), SCSI (2:1), SCSI (3:0), SCSI (3:1).
    - You don't need to account for the OS in the even distribution of disks across controllers, just pick one; the OS doesn't place a substantial load on the controller.
  - g. To provision VMDK disks over 16TB in size, the vSphere web client must be used, the win32 client will return an error.
  - h. Delphix requires 127GB for the system disk. older versions defaulted to 150GB.
    - Due to our unified OVA for masking, the 127GB requirement also applies to Masking Engines
  - i. VMDK for the Delphix Engine OS is often stored on the same VMFS volume as the Delphix VM definition file (aka VMX). In that case, the VMFS volume must have sufficient space to hold the Delphix VMX Configuration, the VDMK for the system disk, a swap/paging area if the memory reservation was not enabled for the Delphix Engine (or to suspend the system), and any related VMware logging.
  - j. Set ESX Storage Multipathing IO optimization ([KB 2072070](#)).
    - i. Set multipathing policy to round-robin.
    - ii. Set path switching IO operation limit to 1 (default 1000).
  - k. Verify that the queue depth setting on the virtual disks used for VMware is appropriate based on the minimum of the HBA type or the underlying storage's combined queue depth for all hosts attached to the same controller
    - See this [VMware KB article](#) for how to check/set the queue depth
2. Testing:
  - a. Run Storage Performance Tool on the raw storage **before any engine configuration**. This is a one-time opportunity for each engine upon installation
  - b. Required maximum storage latency is < 2ms for writes and < 10ms (95th percentile) for small random reads. Minimum passing grades: 4KB/8KB reads (B-), 1MB reads (A), 1KB/128KB writes (A).
  - c. If working with the Delphix Professional Services team, we would expect to run additional baseline performance measurements via composite tools and scripts.
    - e.g. "Sanity Check" (Oracle) or "DiskSpd" (MSSQL)
3. Detail Discussion:
  - a. Before beginning any discussion on storage performance, or at the beginning of the installation, collecting the following specs from your storage administrator will assist in understanding
  - b. Vendor, Model (For example: EMC VMAX 40k, HP 3PAR StoreServ 7000)
  - c. IO latency SLO (For example 5ms 99.999%)
  - d. IOPS/GB SLO (For example: 0.68 IOPS/GB for EMC Gold-1)
  - e. Cache type and size (For example FAST cache 768GB)
  - f. Tier, #Pools; if auto – tiering; relocation schedule (For example: Gold/Silver/Auto/3 pools/etc)
  - g. Pool detail: (#) drives, RPM, Type (For example: Pool1: (20) EFD, (30) 15k SAS, Pool 2: (40) 10k SATA)
  - h. Connection (For example: 16Gb Fibre Channel, 10Gb iSCSI, 20Gb NFS)
  - i. Dedicated or Shared pool (how many applications/servers)

## Data backup and recovery solutions

Cloning an existing Delphix Engine by using hypervisor VM cloning features or by copying existing Engine storage to a new virtual machine is currently not supported. You can choose from the following methods for backup or duplication of an Engine.

## Delphix continuous vault

### Overview

The Delphix Engine has a base feature set that is compelling as a data protection solution. An enhancement is being introduced that can further prevent snapshot and database loss in the event of a ransomware attack.

**Delphix continuous vault** for ransomware protection allows organizations to recover their application data access much faster than traditional backup solutions, in case of malicious attacks.

The Continuous Vault solution provides built-in protection against ransomware attacks by frequently refreshing production application data to a virtual database (dSource), from which you can recover applications almost instantly to any valid point in time prior to the encryption attack by leveraging Delphix VDB provisioning capabilities. The refresh interval between the production application and the Delphix dSource can be configured to be up to seconds, for business-critical applications (not applicable to all DB technologies).

There are two variants of Delphix Continuous Vault:

- **Replica Continuous Vault**, which replicates critical business DB data stored on Delphix Engines to a new target Engine called Replica Continuous Vault.
- **Single Engine Continuous Vault**, which protects critical business DB data stored on a Delphix Engine by preventing manual deletion of protected sources or snapshots.

Once securely stored on the Continuous Vault, the DB data can be used to recover business applications with very low RTO and RPO.

 Requires Technical Services Consult  
Delphix **requires** a Technical Services assessment prior to deployment and configuration of Continuous Vault. The process of configuring a Delphix Continuous Vault replication profile is simple; the assessment is required because each application has specific data protection and recovery requirements and we must ensure that Delphix can respond to them appropriately. To schedule an assessment, please contact your Customer Success Manager.

### Replica continuous vault

The Replica Continuous Vault feature is available via CLI or via the Continuous Vault UI section of the Replication page. This UI provides functions for creating Continuous Vault replication profiles from scratch and converting existing profiles to be locked.

### Advantages

The Replica Continuous Vault variant provides the following advantages:

- Creates a separation of responsibilities between the two Delphix Engines
  - One engine is used for regular Virtualization cases (ingestion, VDBs, SDD)
  - Another engine is used for ransomware protection.
- Creates a physical separation by allowing the admin to isolate and secure the locked Delphix Engine.
  - Only the DSP port has to be open for replication.
  - No ports are needed for JDBC, NFS, or SSH until VDBs need to be created to export data. This also prevents attack vectors related to any of those protocols.
- Can assist with making deployments and security reviews easier to pass since the locked Delphix Engine is isolated and has a single purpose to reduce potential attack vectors.

In the event of a ransomware attack on a primary engine source being compromised or corrupted, you can provision a VDB on the replica in the locked namespace of the replication target – similar to the normal replication namespace. This process can be further outlined in the [Provisioning From Replicated Data Sources or VDBs](#) article. If a complete recovery of the primary engine is needed, please contact Delphix Support.

## Implementation

This feature adds a property to the replication namespace and specifications called “locked”. Additional dSources, VDBs, groups, and domains can be added to locked replication specs, but data sources cannot be removed after doing so. Failover on the target Delphix Engine is not allowed if the namespace is part of the locked replication spec. The retention policy duration on a locked namespace can be modified as long as the duration is either being increased, or it is being decreased to a minimum of 100 days.

The time configuration on Delphix engines with Continuous Vault enabled cannot be changed. This is to prevent attempts at bypassing retention policies in order to try and delete snapshots on the target. Also, the factory reset operation is forbidden when at least one locked replication specification or namespace is present.

A fault is now generated on the Continuous Vault target for a locked namespace that has not received a successful replication update in 12 hours. Upon request, Delphix Support can change this value. New replication specs must also have automatic replication enabled and a satisfactory replication schedule.

## CLI functions

Create a locked replication profile.

```
[user.hostname]> replication spec
[user.hostname] replication spec> create
[user.hostname] replication spec create *> set name=locked-spec-1
[user.hostname] replication spec create *> set objectSpecification.objects=Untitled/
dbname
[user.hostname] replication spec create *> set targetHost=example.delphix.com
[user.hostname] replication spec create *> set targetPrincipal=admin
[user.hostname] replication spec create *> set targetCredential.password=delphix
[user.hostname] replication spec create *> set lockedProfile=true
[user.hostname] replication spec create *> commit
`REPLICATION_SPEC-3
[user.hostname] replication spec> select locked-spec-1
[user.hostname] replication spec 'locked-spec-1'> get
type: ReplicationSpec
name: locked-spec-1
automaticReplication: false
bandwidthLimit: 0
description: (unset)
encrypted: false
lockedProfile: true <----- LOCKED
numberOfConnections: 1
objectSpecification:
  type: ReplicationList
  name: (unset)
  objects: Untitled/dbname
reference: REPLICATION_SPEC-3
runtime:
  type: ReplicationSpecRuntime
```

```

schedule: (unset)
tag: 5570be25-dbcf-48c3-b2d2-dd2c65eb98b7

[user.hostname] policy 'Six Years'>
```

## Single engine continuous vault

This feature is available in versions 6.0.14.0 and above. CLI and UI functions are available for locking dSources.

### Advantages

The Single Engine Continuous Vault provides effective protection against ransomware attacks in a standalone Delphix Engine. This option may be preferable for deployments where maintaining two separate engines is not architecturally necessary.

### Implementation

This feature adds a “locked” property to sources. Once the locked property is enabled, the source cannot be removed. Locked sources are required to have a SnapSync policy defined that refreshes data at least once daily. Furthermore, an alert is raised if no new snapshot or log data is received in the last 12 hours. Upon request, Delphix Support can change this value.

To protect Continuous Vault application data from accidental deletion or malicious attack, snapshots of locked sources may not be manually deleted. These snapshots are managed by a retention policy that must be configured for locked sources. The retention policy duration can be modified as long as retention satisfies the minimum duration (100 days).

As with the Continuous Vault Replication implementation, the time configuration of a Single Engine Continuous Vault cannot be changed. This is to prevent attempts at bypassing retention policies in order to try and delete snapshots on the Continuous Vault. Also, the factory reset operation is forbidden when at least one locked source is present.

By default, locked sources are not required to have LogSync enabled. However, upon request, Delphix Support can configure an engine-wide setting that prevents LogSync from being disabled on a locked source and, optionally, requires LogSync to be enabled from the very beginning—before locking a source.

### CLI functions

Locking a source.

```
sedv> source
sedv source> select src10
sedv source 'src10'> lock
sedv source 'src10' lock *> commit
sedv source 'src10'>
```

Verifying the locked status of a source.

```
sedv source 'src10'> ls
```

```

Properties
  type: OracleLinkedSource
  name: src10
  container: src10
  externalFilePath: (unset)
  linked: true
  locked: true <----- LOCKED
  logCollectionEnabled: false
  operations:
...

```

Verify that a locked source cannot be disabled.

```

sedv source 'src10'> disable
sedv source 'src10' disable *> commit
  Error: The source "src10" cannot be disabled because it is locked.
  Action: Contact Delphix support.
sedv source 'src10' disable *> discard

```

Verify that source locking requires a SnapSync policy that refreshes data at least once daily.

```

# An insufficiently-frequent SnapSync policy: runs at 03:00 on Sundays
sedv policy 'snapsync_weekly'> ls
Properties
  type: SyncPolicy
  name: snapsync_weekly
  customized: false
  default: false

```

Operations

```
delete
update
apply
unapply
```

```
sedv> source
```

```
sedv source> select src10
sedv source 'src10'> lock
sedv source 'src10' lock *> commit
```

Error: The retention policy is less than the minimum "100" days required when applied to locked sources.

Action: Set retention parameters to preserve at least "100" days of data, and [try](#) again.

Verify that a snapshot from a locked source cannot be manually deleted.

```
sedv snapshot '@2022-05-05T22:41:24.045Z'> delete
sedv snapshot '@2022-05-05T22:41:24.045Z' delete *> commit
```

Error: The selected snapshot cannot be deleted because the source associated with its container "Untitled/src10" is locked.

Action: Wait [for](#) the snapshot to be automatically deleted based on its retention policy, or Contact Delphix support.

## Continuous vault alert system

In addition to the data-protection rules described in the previous sections, Continuous Vaults have a special [alert](#) system that notifies administrators about all events that can affect the ability to ingest and replicate locked data or even the ability to send such alerts.

There are two categories of Continuous Vault alerts: domain alerts and system alerts which are emailed to [Delphix administrators](#) and [System administrators](#), respectively. To receive alerts, an administrator must have an email address configured and [SMTP](#) must be enabled.

All Continuous Vault alerts are sent also via [SNMP](#), [Syslog](#) and [Splunk/Fluentd](#) when those services are enabled and their configured severity levels allow for each alert level.

Continuous Vault domain alerts are generated for the following events:

1. Locking a source, replication specification or namespace (informational level).
2. All [actions](#) on locked replication specifications and namespaces, such as changes in replication schedules, and all actions on locked sources and related objects that can affect them, such as changes in environment settings. All action alerts are audit-level alerts.
3. Deleting a Delphix administrator or changing their email address. These are warning-level alerts emailed to the addresses before the change takes effect.

Continuous Vault system alerts are generated for the following events:

1. Modifying, disabling or deleting services used for delivering alerts: SMTP, SNMP, Syslog and Splunk/Fluentd. These are warning-level alerts sent using the service configurations before the change takes effect.
2. Creating or enabling such a service (informational level).
3. Deleting a System administrator or changing their email address. These are warning-level alerts emailed to the addresses before the change takes effect.

By default, system administrators are allowed to change these service configurations. Continuous Vaults only notify when those changes happen. However, upon request, Delphix Support can enable locking these services such that, once an administrator enables a service, that service cannot be changed (except for subsequent changes requested to Delphix Support).

## Backup and recovery strategies for the Delphix engine

As a software virtual appliance, Delphix leverages features of the storage, hypervisor, and appliance infrastructure to provide for recovery in the event of failure. These topics walk through the process of evaluating requirements and defining a solution. This process depends on the requirements and features of the environment in which the Delphix Engine is deployed.

- [Backup and recovery requirements](#)
- [Backup solution implementation](#)
- [Deployment architecture](#)
- [Mapping requirements to solutions](#)

## Backup and recovery requirements

This topic describes determining requirements for infrastructure failure modes and recovery.

Before devising a strategy, you must first have a set of requirements to evaluate possible solutions. What failures are you trying to protect against, and what are your recovery goals in the event of failure?

### Failure points

Before devising a strategy, you must first have a set of requirements by which the resulting solution can be evaluated. What failures are you trying to protect against, and what are your recovery goals in the event of failure?

#### Physical server failure

The Delphix Engine runs within the VMware ESX hypervisor, which itself is running on a physical machine. Failure of that physical machine will affect the Delphix Engine, as well as any other virtual machines running on that server. The failure is isolated to that particular server and is not the result of a larger, site-wide failure.

- **Recommendation:** ESX Clustering

#### Storage failure

The Delphix Engine uses LUNs from a storage array provided through the VMware hypervisor. The storage array may have redundant disks and/or controllers to protect against single points of failure within the array. However, the Delphix Engine can still be affected by a failure of the entire array, the SAN path between the Delphix Engine and the array, or by a failure of the LUNs in the array that are assigned to the Delphix Engine.

- **Recommendation:** Replication

#### Site failure

When an entire site or datacenter goes down, all servers, storage, and infrastructure are lost. This will affect not only the Delphix Engine but any production databases and target servers in the datacenter.

- **Recommendation:** Replication

#### Administrative error

If an administrator mistakenly deletes a VDB or takes some other irreversible action, there is no method of recovery built into the Delphix Engine.

- **Recommendation:** Snapshots

### Recovery objectives

Once infrastructure fails, some amount of work is required to restore the Delphix Engine to an operational state. Clients won't have access to the Delphix Engine during this time, and the point to which the system is recovered is dependent on the mechanism being used. These qualitative aspects of recovery can be captured by the following metrics. As these metrics are often directly associated with cost, it is important to think not just about the desired metrics, but also the minimum viable goals.

#### Recovery point objective (RPO)

The RPO is the acceptable amount of data that can be lost in the event of a failure. For example, if backups are taken once a day, then at most 24 hours of data will be lost if the system fails immediately before a regularly scheduled backup.

#### Recovery time objective (RTO)

The RTO is the time required to restore the system to an operational state after a failure. For example, recovery may require restoring data from a backup, followed by some number of manual steps to recreate the configuration in the new system. RTO is equivalent to the downtime experienced by clients.

#### Recovery time granularity (RTG)

The granularity of the recovery time is the specificity by which you can select a particular point in time from the past to restore the system. For example, VM snapshots taken every hour provide no way to restore to a point in time between those snapshots.

## Backup solution implementation

This topic describes the tradeoffs involved with backup and recovery solutions.

With the exception of clustering, solutions can be implemented using features at both the storage and hypervisor layer. Choosing the right technology requires understanding both your requirements and what infrastructure is in use in your environment. The following sections outline some basic choices and the tradeoffs involved.

### Clustering

VMware [vSphere's high](#) availability provides the ability to have a VM configuration shared between multiple physical ESX servers. Once the storage has been configured on all physical servers, any server can run the Delphix Engine VM. This allows ESX clusters to survive physical server failure. In the event of failure, the VM is started on a different server and appears to clients as an unexpected reboot with non-zero but minimal downtime. Depending on the length of the outage, this may cause a short pause in I/O and database activity, but longer outages can trigger timeouts at the protocol and database layers that result in I/O and query errors. Such long outages are unlikely to occur in a properly configured environment.

Automatic detection of a failure in an HA environment does not work in all circumstances, and there are cases where the host, storage, or network can hang such that clients are deprived of access, but the systems continue to appear functional. In these cases, a manual failover of the systems may be required.

When configuring a cluster, it is important to provide standby infrastructure with equivalent resources and performance characteristics. Asymmetric performance capabilities can lead to poor performance in the event of a failover. In the worst case of an over-provisioned server, this can cause widespread workload failure and the inability to meet performance SLAs.

### Snapshots

VMware provides [storage-agnostic snapshots](#) that are managed through the [VMware Snapshot Manager](#). The use of VMware snapshots can, however, cause debilitating performance problems for write-heavy workloads due to the need to manage snapshot redo-log metadata. In order to provide an alternative snapshot implementation, while retaining the existing management infrastructure, VMware has created an API to allow storage vendors to supply their own snapshot implementation. This is only supported in ESX 5.1. Furthermore, the array must support the [vStorage APIs](#). Consult the [VMware documentation](#) for supported storage solutions and the performance and management implications.

Storage-based snapshots, by virtue of being implemented natively in the storage array, typically do not suffer from such performance problems and are preferred over VMware snapshots when available. When managing storage-based snapshots, it is critical that all LUNs backing a single VM be part of the same consistency group. Consistency groups provide write order consistency across multiple LUNs and allow snapshots to be taken at the same point in time across the LUNs. This must include all VM configuration, system VMDKs, and VMDKs that hold the dSources and VDBs. Each storage vendor presents consistency groups in a different fashion; consult your storage vendor documentation for information on how to configure and manage snapshots across multiple LUNs.

In the event of a snapshot recovery becoming required, ensure that the Delphix Engine VM is powered off for the duration of the snapshot recovery. Failure to do so can lead to filesystem corruption as you're changing blocks underneath a running system.

### Replication

[Site Recovery Manager](#) (SRM) is a VMware product that provides replication and failover of virtual machines within a vSphere environment. It is primarily an orchestration framework, with the actual data replication performed by a native VMware implementation, or by the storage array through a storage replication adapter (SRA). A list of

supported SRAs can be found in the [VMware documentation](#). There is some performance overhead in the native solution, but not of the same magnitude as the VMware snapshot impact. SRAs provide better performance but require that the same storage vendor be used as both source and target, and require resynchronization when migrating between storage vendors.

Storage-based replication can also be used in the absence of SRM, though this will require manual coordination when re-configuring and starting up VMs after failover. The VM configuration, as well as the storage configuration within ESX, will have to be recreated using the replicated storage.

The Delphix Engine also provides native replication within Delphix. This has the following benefits:

- The target system is online and active
- VDBs can be provisioned on the target from replicated objects
- A subset of objects can be replicated
- On failover, the objects are started in a disabled state. This allows configuration to be adjusted to reflect the target environment prior to triggering policy-driven actions.
- Multiple sources can be replicated to a single target

Note that the Delphix Engine currently only replicates data objects (dSources and VDBs) and environments (source and target services). It does not replicate system configuration, such as users and policies. This provides more flexibility when mapping between disparate environments, but requires additional work when instantiating an identical copy of a system after failover.

## Backup

There is a large ecosystem of storage and VM-based backup tools, each with its own particular advantages and limitations. VMware provides [Data Protector](#), but there are [size limitations](#) (linked to a maximum of 2TB of deduped data) that make it impractical for most Delphix Engine deployments. Most third-party backup products, such as Symantec NetBackup, EMC Networker, and IBM Tivoli Storage Manager, have solutions designed specifically for the backup of virtual machines. Because the Delphix Engine is packaged as an appliance, it is not possible to install third-party backup agents. However, any existing solution that can back up virtual machines without the need for an agent on the system should be applicable to Delphix as well. Check with your preferred backup vendor to understand what capabilities exist.

Some storage vendors also provide a native backup of LUNs. Backup at the storage layer reduces overhead by avoiding data movement across the network but loses some flexibility by not operating within the VMware infrastructure. For example, recreating the VM storage configuration from restored LUNs is a manual process when using storage-based recovery.

## Deployment architecture

This topic describes components of the Delphix deployment architecture.

Delphix operates in a virtual environment with several core systems working in concert, each with its own set of capabilities. Understanding this architecture is critical in evaluating how solutions can be applied across the components, and the tradeoffs involved.

### Architectural components

This diagram illustrates Delphix's recommended best practices for deploying the Delphix Engine in a VMware environment:

This architecture is designed to isolate I/O traffic to individual LUNs while using the most commonly deployed VMware components. In this example, each VMDK file is placed in a separate VMFS volume. Each volume is exported to every node in the ESX cluster, allowing the Delphix Engine to run on any physical host in the cluster.

### Fault Recovery Features

Across the recommended deployment architecture there are three key components in play: Delphix Engine, VMware, and storage. Each of these provides different failure handling capabilities, which can be roughly grouped into the following areas.

### Server Clustering

Clustering provides a standby server that can take over in the event of failure. A given clustering solution may or may not provide high availability guarantees, though all provide failover capabilities, provided that an identical passive system is available.

### Snapshots

Snapshots preserve a point-in-time copy of data that can be used later for rollback or to create writable copies. Creating a snapshot is typically low cost in terms of space and time. Because they use the storage allocated to the array, snapshots restore quickly, but they do not protect against failures of the array.

### Replication

Data replication works by sending a series of updates from one system to another in order to recreate the same data remotely. This stream can be synchronous, but due to performance considerations is typically asynchronous, where some data loss is acceptable. Replication has many of the same benefits of backup, in that the data is transferred to a different fault domain, but has superior recovery time given that the data is maintained within an online system. The main drawback of replication is that the data is always current - any logical data error in the primary system is also propagated to the remote target. The impact of such a failure is less when replication is combined with snapshots, as is often the case with continuous data protection (CDP) solutions.

### Backup

Like snapshots, backup technologies preserve a point-in-time copy of a storage dataset, but then move that copy to offline storage. Depending on the system, both full and incremental backups may be supported, and the backup images may or may not be consistent. Backup has the advantage that the data itself is stored outside the original fault domain, but comes at high cost in terms of complexity, additional infrastructure, and recovery time.

## Mapping requirements to solutions

This topic describes how to map from backup and recovery requirements to solutions.

With requirements and detailed knowledge of the deployment architecture, we can map to solutions tailored for the features provided by the underlying infrastructure.

### Feature capabilities

Based on these failure points and recovery features, you can use the following table to map requirements to architectural components: VMware (V), Delphix (D), or storage (S). This can drive implementation based on infrastructure capabilities and recovery objectives.

Failure Point	Fault Recovery Features			
	Clustering	Snapshots	Replication	Backup
Server Failure	V	-	V S D	-
Storage Failure	-	-	V S D	V S
Site Failure	-	-	V S D	V S
Administrative Error	-	V S	-	V S

### Recovery Point Objective (RPO)

Feature	Time	Description
<b>Clustering</b>	Zero	All changes committed to disk are automatically propagated to the new server. Any pending changes in memory are lost.
<b>Replication</b>	Near zero	Most solutions offer scheduled replication, but many can offer continuous replication with near-zero data loss.
<b>Snapshots</b>	Snapshot period (for example, one hour)	Given their relatively low cost, snapshots tend to be taken at a higher frequency than a traditional backup schedule.
<b>Backup</b>	Backup period (for example, one day)	Backup policies can be configured in a variety of ways, but even with incremental backups, most deployments operate no more frequently than once a day because of the cost of full backups, and the impact of incremental backups on recovery time.

## Recovery time objective (RTO)

Feature	Time	Description
<b>Clustering</b>	Near zero	VM clustering with the Delphix Engine provides near-zero downtime in the event of failure, but clients may be briefly paused or interrupted.
<b>Replication</b>	15 minutes	The target side environment is kept in hot standby mode, so it is relatively quick to switch over to the target environment. Depending on the scope of the failure, however, some configuration information may need to be changed on the target side prior to enabling operation.
<b>Snapshots</b>	15 minutes	The Delphix Engine can be rolled back to a previous state. Changes made to systems external to the Delphix Engine (for example, deleting a VDB) can cause inconsistencies after rollback.
<b>Backup</b>	Hours or days	Restoring a full backup can be very time-consuming. In addition to having to read, transfer, and write all of the data, the same process will need to be run for each incremental backup to reach the objective point.

## Recovery time granularity

Feature	Granularity	Description
<b>Clustering</b>	None	Only the current system state can be recovered.
<b>Replication</b>	None	Only the nearest replicated state can be recovered unless combined with snapshots.
<b>Snapshots</b>	Snapshot period (for example, one hour)	Determined by the snapshot schedule.
<b>Backup</b>	Backup period (for example, one day)	Determined by the backup schedule.

## Delphix replication

## Replication overview

Delphix allows data objects to be replicated between Delphix Engines. Prior to version 5.3.3, these Delphix Engines had to be running identical Delphix versions, but could otherwise vary in terms of other configurations. With version 5.3.3 and above, engines can now be on different versions, which is further detailed in the Forward Compatible Replication (FCR) section. In the event of a failure that destroys the source engine, you can bring up the target engine in a state that matches the source. In addition, you can provision VDBs from replicated objects, allowing for the geographical distribution of data and remote provisioning.

You can run replication ad hoc, but it is typically run according to a predefined schedule. After the initial update, each subsequent update sends only the changes incurred since the previous update. Replication does not provide synchronous semantics, which would otherwise guarantee that all data is preserved on the target engine. When there is a failover to a replication target, some data is lost, equivalent to the last time a replication update was sent.

Replication is generally not suited for high-availability configurations where rapid failover (and failback) is a requirement. Failing over a replication target requires a non-trivial amount of time and is a one-way operation; failback requires replicating all data back to the original source. For cases where high availability is necessary, it is best to leverage features of the underlying hypervisor or storage platform. For more information on how to evaluate the use of Delphix Engine replication for your data recovery requirements, see the topics under [Backup and Recovery Strategies for the Delphix Engine](#).

### Forward compatible replication (FCR)

Delphix Virtualization supports the ability to replicate to a Delphix Target Engine running on a higher version. To do so, FCR has a few requirements and restrictions to consider:

- FCR is supported for replication jobs starting from a **source engine** running 5.3.0.0 and beyond.
- The **target engine** must be running 5.3.3.0 and beyond.
- As of 6.0.10.0, the FCR replication operation can not go beyond engine versions released more than 12 months apart.
- FCR supports replicating between major versions as long as those specific versions are no more than a year apart.

#### Examples of supported and not supported FCR configurations:

##### Supported

- 6.0.3.0 to 6.0.3.0 (same version)
- 6.0.3.1 to 6.0.3.1 (same version)
- 6.0.3.0 to 6.0.3.1 (higher patch version)
- 6.0.3.1 to 6.0.5.0
- 6.0.3.0 to 6.0.9.0
- 6.0.4.0 to 6.0.10.0

##### Not supported

- 5.2.5.0 to 6.4.0.0 (source version not compatible with FCR)
- 5.3.0.0 to 5.3.2.0 (target version not compatible with FCR)
- 6.0.9.0 to 6.0.8.0 (source version higher than the target)
- 6.0.0.0 to 6.0.10.0 (there is more than a year between release dates for those versions)

##### Exceptions

Some of the newer versions of 5.3.x are not compatible with the early versions of 6.0.x.0 (6.0.0.0 and 6.0.1.0).

- 5.3.7.0 and 5.3.7.1 are not compatible with 6.0.0.0

- 5.3.8.0 and 5.3.8.1 are not compatible with 6.0.0.0
- 5.3.9.0 is not compatible with 6.0.0.0
- 5.3.9.0 is not compatible with 6.0.1.0 and 6.0.1.1

Replication matrix

The following table lists all the Delphix Engine versions that a user can replicate to the required or the latest version.

When replicating from X.Y.X.\* to X.Y.Z.\* the target version has to be greater than or equal to the source version. We are using the \* convention to refer to patch releases and reduce the table size.

From Source Version	To Target Version
<b>Replication Supported</b>	
5.3.0.*	5.3.0.* 5.3.3.* - 6.0.9.*
5.3.2.*	5.3.2.* - 6.0.9.*
5.3.3.*	5.3.3.* - 6.0.9.*
5.3.4.*	5.3.4.* - 6.0.9.*
5.3.5.*	5.3.5.* - 6.0.9.*
5.3.6.*	5.3.6.* - 6.0.9.*
5.3.7.*	5.3.7.* - 5.3.9.* 6.0.1.* - 6.0.9.*
5.3.8.*	5.3.8.* - 5.3.9.* 6.0.1.* - 6.0.9.*
5.3.9.*	5.3.9.* 6.0.2.* - 6.0.9.*
6.0.0.*	6.0.0.* - 6.0.7.*
6.0.1.*	6.0.1.* - 6.0.7.*
6.0.2.*	6.0.2.* - 6.0.7.*

<b>From Source Version</b>	<b>To Target Version</b>
6.0.3.*	6.0.3.* - 6.0.7.*
6.0.4.*	6.0.4.* - 6.0.7.*
6.0.5.*	6.0.5.* - 6.0.11.*
6.0.6.*	6.0.6.* - 6.0.12.*
6.0.7.*	6.0.7.* - 6.0.13.*
6.0.8.*	6.0.8.* - 6.0.14.*
6.0.9.*	6.0.9.* - 6.0.15.*
6.0.10.*	6.0.10.* - 6.0.16.*
6.0.11.*	6.0.11.* - 6.0.17.*
6.0.12.*	6.0.12.* - 7.0.0.*
6.0.13.*	6.0.13.* - 9.0.0.*
6.0.14.*	6.0.14.* - 10.0.0.*
6.0.15.*	6.0.15.* - 10.0.0.*
6.0.16.*	6.0.16.* - 10.0.0.*
6.0.17.*	6.0.17.* - 10.0.0.*
7.0.0.*	7.0.0.* - 10.0.0.*
8.0.0.*	8.0.0.* - 10.0.0.*
9.0.0.*	9.0.0.* - 10.0.0.*
10.0.0.*	10.0.0.*

## Replication features

As virtual appliances, it is possible to backup, restore, replicate, and migrate data objects between Delphix Engines using features of VMWare and the underlying storage infrastructure. Data objects include groups, dSources, VDBs, Self-Service (Jet Stream) data templates and data containers, and associated dependencies. In addition to the replication capabilities provided by this infrastructure, native Delphix Engine replication provides further capabilities, such as the ability to replicate a subset of objects, replicate multiple sources to a single target, and provision VDBs from replicated dSources and VDBs without affecting ongoing updates. The topics under [Backup and Recovery Strategies for the Delphix Engine](#) provide more information on how to evaluate features of the Delphix Engine in relation to your backup and recovery requirements.

Replication is configured on the source Delphix Engine and copies a subset of dSources and VDBs to a target Delphix Engine. It then sends incremental updates manually or according to a schedule. For more information on configuring replication, see [Configuring Replication](#).

You can use replicated dSources and VDBs to provision new VDBs on the target side. You can refresh these VDBs to data sent as part of an incremental replication update, as long as you do not destroy the parent object on the replication source. For more information, see [Provisioning from Replicated Data Sources or VDBs](#).

During replication, replicated dSources and VDBs are maintained in an alternate replica and are not active on the target side. In the event of a disaster, a failover operation can break the replication relationship. For more information on how to activate replicated objects, see [Replicas and Failover](#).

## Replication details

When you select objects for replication, the engine will automatically include any dependencies, including parent objects, such as groups, and data dependencies such as VDB sources. This means that replicating a VDB will automatically include its group, the parent dSource, and the group of the dSource, as well as any environments associated with those databases. When replicating an entire engine, all environments will be included. When replicating a database or group, only those environments with the replicated databases are included.

Only database objects and their dependencies, as well as certain non-database objects, are copied as part of a backup or replication operation, including:

- dSources
- VDBs
- Groups
- Self-service (Jet Stream) Data Templates and Data Containers
- Environments
- Environment configuration (users, database instances, and installations)
- Delphix users, roles, permissions, and authorizations
- Policies
- Database configuration templates

The following objects are NOT copied as part of a backup or replication operation:

- Events and faults
- Job history
- System services settings, such as SMTP
- Hook templates
- Alert profiles

After failover, you must recreate these settings on the target.

 On-Premises Replication To Azure/OCI/GCP/Hyper-V

Replicating from on-premises engines with an underlying storage block size of 512B will experience disk usage inflation when replicating to target engines with different underlying block sizes. Azure, GCP, Hyper-V, and OCI are known to have 4K block sizes and therefore will require extra disk capacity when receiving replication from an on-premises engine. This behavior is due to the fact that the underlying storage block size is different (512B vs. 4K) between the two Delphix Engines (one on Prem, one on Azure/OCI/GCP/Hyper-V), resulting in a lower compression rate on the replication target. It is expected that 1.5-1.6x the amount of space is taken from objects on-premises in these cases.

## Resumable replication

Resumable replication enhances the current replication feature by allowing you to restart large, time-consuming initial replication or incremental updates from an intermediate point. A single replication instance can fail for a number of environmental and internal reasons. Previously, when you restarted a failed replication instance, replication required a full resend of all data transmitted prior to the failure. With resumable replication, no data is retransmitted. Replication is resumable across machine reboot, stack restart, and network partitions. The resumable replication feature is fully automated and does not require or allow any user intervention.

For example, suppose a replication profile has already been configured from a source to a target. A large, full send begins between the two that is expected to take weeks to complete. Halfway through, a power outage at the data center that houses the source causes the source machine to go down and only come back up after a few hours. On startup, the source will detect a replication was ongoing, automatically re-contact the target, and resume the replication where it left off. In the user interface (UI) on the source, the same replication sends job will appear as active and continue to update its progress. However, in the UI of the target, a new replication receives job will appear but will track its progress as a percentage of the entire replication.

In 4.1 and earlier releases, the replication component would always clean up after failed jobs to ensure that the Delphix Engine was kept in a consistent state and that no storage was wasted on unused data. With the addition of reusability, the target and source can choose to retain a partial replication state following a failure to allow future replications to complete from that intermediate point. In the current release, the target and source will only choose to retain partial replication state following failures that leave them out of network contact with each other – for example, source restart, target restart, or network partition. Once network contact is re-established, the ongoing replication will be automatically detected and resumed.

Replication will not resume after failures that leave the source and target connected. For example, if a storage failure on the target, such as out-of-space errors, causes a replication to fail, the source and target remain connected. As a result, the Engine will discard state data associated with the failed Replication operation. Nonetheless, resumable replication would begin during a source reboot, a target reboot, and a network partition.

## Replicating Delphix self-service templates

Templates can now be replicated and accessed on the target engine via Delphix Self-Service (Jet Stream). Replicated templates can be replicated into the target space with or without their containers. On the new target engine, the newly created replicated template can be used to create new containers that are assigned to users. You cannot change the replicated template's name or the names of the containers from which it was replicated.

Any containers that were replicated over with the template cannot be used to start, stop, etc until they are disconnected to their parent containers in the source engine during the failover operation.

## Replication of non-data objects

As of 6.0.5.0, the replication of non-data objects is supported.

**Non-data objects** refer to:

- Delphix users, roles, permissions, and authorizations
- Policies
- Database configuration templates

These objects will not be presented as selectable objects when creating a replication spec, but will instead be passively included by association, the same way environments are. Replication of non-data objects will follow these rules:

- If the entire engine is replicated, all non-data objects will be included
- If specific data objects are replicated, all associated non-data objects will be included

For example, when a container is replicated, then policies that apply to that container, as well as users who have authorizations on that container, will all be included for replication.

Replicated users will be shown on the Received Replicas page on the Delphix Engine UI.

Also as of 6.0.5.0, the [automatic conflict resolution](#) option is chosen by default; it is the recommended way of handling the failover of non-data objects, as non-data objects are expected to cause collisions. Automatic conflict resolution will resolve non-data object conflicts by the following rules:

- Users will be consolidated if both username and email match. Otherwise, the replicated user will be renamed.
- Roles, permissions, and authorizations will be consolidated
- Policies and database configuration templates will be renamed, except for "None" type policies, which will be consolidated. Following failover, replicated policies will continue to apply to the same replicated data objects.

## Replication concepts

Delphix replication allows you to copy objects from one Engine (referred to as a source Engine) to another Engine (referred to as a target Engine).

Replication recreates objects from the source Engine onto the target Engine in a **replica**, also known as a **namespace**, that preserves object relationships and naming on the target Engine without interfering with its active objects. Objects within a replica are read-only and disabled until the replica is failed over, at which point they can be activated. VDBs and dSources within a replica can be used as the source for provisioning new VDBs. Below are key concepts for replication that will be explained in detail:

- **Received Replicas or Namespaces:** Once replication is complete, the target Engine will create a received replica, also known as a namespace. This is a copy of objects that are related via a grouping.
- **Failover and Conflict Resolution:** Certain objects may require changes to resolve conflicts prior to completing a replication failover. Names of replicated objects should be unique for replication to complete successfully
- **Enabling Databases and Environments:** Once replication takes place, you must enable the databases and environments on the target engine. This step ensures the configuration of these objects is correct and will ensure that replication has correctly copied the necessary object relationships from the source engine.

### Received replicas or namespaces

A replica contains a set of replicated objects, such as dSources and VDBs. These objects are read-only and disabled while replication is ongoing. You may view replicated objects both in the Delphix Engine UI as well as the CLI. To view received replicas:

1. On the target Engine, navigate to 'System'. Then select Replication.
2. Under Received Replicas, select the replica.

On this screen, you can browse the contents of replicas, as well as failover or delete individual replicas.

Deleting or failing over a replica will break any link with the replication source. Subsequent incremental updates will fail, requiring the source to re-establish replication. Failover should only be triggered when no further updates from the source are possible, as in a disaster scenario. Various replication use cases are also described in [Replication Use Cases](#).

Multiple replicas can exist on the system at the same time. Active objects can exist in the system alongside replicas without interfering with replication updates. You can also use VDBs and dSources within a replica as a source when provisioning. For more information, see [Provisioning from Replicated Data Sources or VDBs](#).

### Failover and conflict resolution

To activate the objects in a replica, you must first fail over the replica. This will disconnect the replication connection and move the objects to the live system, where they can be actively used.

During the replication failover, there may be objects that conflict between the source Engine and the target Engine. For example, 'groups' will conflict if the failing over group has the same name as a group in the live system, as well as environments, dSources, and VDBs. By default, active objects with conflicting names will cause an error at the time of failover. In these scenarios, you must rename the active objects before the failover operation can complete successfully.

Given that conflicting names prevent failover from succeeding, best practices in a disaster recovery situation are to leave the target system completely passive with no active objects until the time that failover is required.

Once a replica is failed over, the objects are active but will be automatically disabled. The next section describes enabling these objects after replication is complete.

## Enabling databases and environments

Objects may refer to states (IP addresses, mount paths, etc.) that differ between the source and target Engines. Because of this, all databases and objects within a replica are automatically disabled after a failover. This allows the administrator to alter configuration prior to enabling databases and environments, without the system inadvertently connecting to invalid systems.

After failover is complete, you must explicitly enable all dSources, VDBs, and environments. If you need to change any configuration for the target environment, you can do so prior to enabling the objects. In the event that a failing-over environment is consolidated with a live system environment, it must be refreshed before all of its databases can be used.

## Replication use cases

Replication allows you to move Delphix objects such as dSources and virtual databases (VDBs) between Delphix Engines. These topics describe how you can use replication to meet different use cases:

- **Replicating to the Public Cloud:** With Delphix replication you can send data from engines deployed on-premise to the public cloud. In this case, you may have a Delphix engine in the production zone to ingest data securely with replication set up to the public cloud for development access and rapid, on-demand testing.
- **Disaster Recovery:** In the event of a disaster, you may need to failover your engine. Delphix replication enables you to configure a failover Delphix Engine to preserve the data and Delphix objects from the source engine for disaster recovery.
- **Geographically Distributed Development:** Often, development teams access data from all over the world. In this scenario, you may want to replicate data to be local to the developers who require access. With Delphix replication, you can provide developers with local access to Delphix datasets.
- **Data Migration:** Delphix supports simple migration of data and resources between Delphix Engines. There may be cases when you need to consolidate workloads between different Delphix Engines. With replication, you can easily migrate data as needed.

With Delphix replication, you can achieve the ideal Delphix deployment:

1. Ingesting data in production with a Delphix Engine deployed within the production zone.
2. Masking the data in production using [Delphix Masking](#).
3. Replicating the masked data to a non-production environment, using Selective Data Distribution (SDD). SDD enables you to securely replicate masked data without compromising sensitive data from the source engine. For more information, read [Selective Data Distribution Overview](#).

For more information on a few examples of Replication use cases, view the sections below.

### Replicating to the public cloud

Enterprises will usually have the separate infrastructure for production systems and non-production development environments. For example, in the hybrid-cloud model, on-premise data centers are used to allow the company maximum ownership of these systems, while the public cloud is leveraged by development and automated testing teams to accelerate software development.

### Delphix engine deployed in the public cloud

- Once a Delphix Engine has been deployed in the public cloud (using a supported cloud platform as described in [Deployment](#)) you can begin replicating from any source engine to that target engine.
- This enables you to provide access to production data from a Delphix Engine deployed on-premise to a Delphix Engine deployed in the cloud platform of your choice.

### Disaster recovery

Replication is often used to provide recovery in the event of a disaster, where a data center or site becomes completely unavailable. To prepare for this, you may configure a failover Delphix Engine, which we will refer to as the *replication target Engine*. This target Engine will regularly receive replication updates from the original, or source, Engine so that if the source ever becomes unavailable, the target can be activated immediately.

### Configuration steps

- **Passive target engine**

- For disaster recovery, the target engine should be kept in a passive state until the source engine is lost. This prevents failover conflicts that may occur during the replication process.
- At this point, a failover is performed that breaks subsequent replication updates and activates objects so that you can manage them on the target side.
- **Same configuration for source and target engines**
  - Target hosts and systems should exist at the target that matches the configuration of those at the primary engine. For example, if the source engine has two Red Hat environments discovered with four Oracle databases, the target engine should have exactly two Red Hat environments and four Oracle databases as well.
  - The failover engine should be provisioned with identical resources as the primary engine. For example, both engines should have the same number and types of disks attached as storage.
  - Finally, both engines should have the same network and storage topologies.

## Failover object management

Once a failover occurs, there are two scenarios that will affect how you manage replicated objects, which include dSources, VDBs, and Environments.

- **Failure of Infrastructure Running the Delphix Engine Only**
  - You can enable dSources and VDBs and reconnect to the original environments that existed on the Source Engine.
  - You can reconfigure environments on the target Engine prior to failover as well.
- **Failure of Infrastructure Running the Delphix Engine and Delphix-connected Environments**
  - Environments will then have to be adjusted to point to the new systems on the target side.
  - If there is not a 1:1 mapping, then you can migrate the VDBs to new systems on the target, and you can detach dSources and attach them to the standby system in the target environment.

Follow the best practices below to simplify failover and meet performance expectations in the event of a disaster:

- To the extent possible, the failover Engine should mirror the primary Engine
  - Maintain a 1:1 relationship between source and targets. All data-related objects such as dSources, VDBs, and Environments as well as their configurations such as users and policies.
- The target Engine should remain passive and not be actively used for other workloads

## Geographically distributed development

Organizations often have development teams distributed across different networks as well as different geographical locations. To improve performance or even meet security requirements, it may be necessary to replicate data from one location to another. The Delphix Engine allows for VDBs to be provisioned from replicated dSources and VDBs, as described in [Provisioning from Replicated Data Sources or VDBs](#).

This use case differs from **Disaster Recovery** as replication is never broken and failover is never performed. You can refresh remote VDBs as long as the parent objects continue to exist on the source. If they are deleted, then remote VDBs will continue to exist but cannot be refreshed or updated from their original source VDB.

### Configuration steps

- **Avoid Heavy VDB Workloads on the Source:** Because each replication stream induces load on the source system:
  - Minimize the number of simultaneous replication updates. Each source engine can support replicating to multiple target engines, but you should try to keep simultaneous updates to under three target engines per source.
  - If possible, avoid heavy VDB workloads on the Source Engine
- **The permanence of Source Objects:** Provision only from sources that are effectively permanent, since replicated VDBs cannot be refreshed once the source is deleted. If you delete a source object you will need to re-replicate the VDBs if they need to be refreshed.

- **Additional Storage Capacity on the Target Engine:** Provision additional storage capacity on the target Engine
  - Remotely provisioned VDBs can consume shared storage (via NFS mounts) on the target even when the parent is deleted on the source

This use case supports more complex models such as 1-to-many and many-to-1. However, replication can only replicate objects that exist in the primary namespace. Consider a Delphix deployment with three Engines: Engine A, Engine B, and Engine C. The following workflow **is supported**:

1. **Engine A Replicates to Engine B**
2. **Provision a Replica VDB on Engine B**
3. **Engine B Replicates to Engine C**

In this scenario, you can replicate from Engine A to Engine B. Then, on Engine B provision a replica VDB into the primary namespace. Finally, add that object into a replication specification to replicate to Engine C. **Note:** Engine B can only replicate objects that exist in the primary (live) namespace to Engine C.

It is important to note the interim step of provisioning an on Engine B is required. For example, the following usage **is not allowed**:

1. **Engine A Replicates to Engine B**
2. **Engine B Replicates to Engine C**

You can replicate from Engine A to Engine B. But on Engine B, it is not possible, nor supported, to create a replication specification with objects in the replication namespace that are desired to be replicated to Engine C.

## Data migration

You can use replication to perform a one-time migration of resources, such as virtual databases or environments, from one Delphix Engine to another. While the hypervisor provides tools to move virtual appliances between physical systems, there are times when migration is necessary, such as:

- Migrating between different physical storage
- Consolidating or distributing workloads across Delphix Engines

In these cases, you can use replication to copy a subset of objects across different topologies.

For migration, follow these best practices:

- Send full updates, followed by incremental updates, until the time required for incremental updates meets your downtime window
- Disable all objects to be migrated on the source, to ensure that they are not actively changing
- Send a final incremental update before failing over the target Engine
- After failover, delete any migrated objects on the source, or the entire Engine

## Configuring replication

This topic describes how to configure data replication between Delphix Engines. Replication is configured with *Replication Profiles* that contain options such as the replication schedule, the hostname of the target Engine, and the selected objects that will be replicated.

### Requirements

- **Version requirements:** the replication target can be on the same or newer version than the replication source.
- **Engine communication:** The target Delphix Engine must be reachable from the source Engine.
- **Storage allocation:** The target Delphix Engine must have sufficient free storage to receive the replicated data.
- **Privilege requirements:** The user in the replication profile must have administrative privileges on the source and the target engines.

### Configuring the network

Delphix Replication uses a private network protocol to communicate between two Delphix Engines. You may specify a network interface to run replication by configuring routing to direct traffic over a particular interface.

The replication network protocol uses TCP port 8415. If there is a firewall between the source and target that is blocking this port, then there are two possible solutions:

1. Enable port 8415 on the firewall in order to allow connections to this port from the source to the target.
2. Replication can connect through a SOCKS proxy if one exists. Configure the SOCKS proxy address and port by connecting to the command-line interface (CLI) as a system administrator user and navigating to "service proxy" to update the SOCKS configuration.

**Note:**

Port 1080

SOCKS port 1080 is used by default but can be overridden

Replication can connect through a SOCKS proxy if one exists. Configure the SOCKS proxy address and port by connecting to the command-line interface (CLI) as a system administrator user and navigating to "service proxy" to update the SOCKS configuration. Example:

#### Example of a SOCKS Proxy

```
dlpx-engine> service proxy
dlpx-engine service proxy> update
dlpx-engine service proxy update *> set socks.enabled=true
dlpx-engine service proxy update *> set socks.host=10.2.3.4
dlpx-engine service proxy update *> set socks.username=someuser
dlpx-engine service proxy update *> set socks.password=somepassword
dlpx-engine service proxy update *> commit
dlpx-engine service proxy> get
  type: ProxyService
  https:
    type: ProxyConfiguration
    enabled: false
    host: (unset)
    password: (unset)
    port: 8080
```

```

username: (unset)
socks:
  type: ProxyConfiguration
  enabled: true
  host: 10.2.3.4
  password: *****
  port: 1080
  username: someuser

```

## Configuring the replication source Delphix engine

1. On the source Delphix Engine, click **System**, then **Replication**.
2. In the left-hand navigation section, click **Create Profile**.
3. Enter the following required fields:
  - a. Name of the replication profile
  - b. The hostname or IP address for the target Delphix Engine.

## Replication profile options

There are several configuration options for your replication profiles. These give you more granular control on options such as when replication will run, how much bandwidth it may use, and which objects are replicated. Details for each option are described below.

**i** The following configurable options are static and can not be configured at run-time. You can set these configurations while a replication spec is being executed, but the values will be applied only after the next execution.

- **Automatic replication:** A policy to automatically run replication. With this option, you can set up replication based on the schedule you need. Automatic replication allows you to define a policy to automatically run replication. By default, automatic replication is disabled, meaning that you must trigger replication updates manually. To enable automatic replication, click the Enabled checkbox. With this setting, you can enter the frequency and time for replication updates to the target Delphix Engine. Automatic replication uses Quartz, a job scheduling tool (<http://www.quartz-scheduler.org/>), for scheduling, which can be configured via the Advanced option.
- **Traffic Options:** Various traffic and bandwidth options are available. For example, you may want to enable encrypted traffic or limited bandwidth during replication updates.
  - **Encrypting traffic:** By default, replication streams are unencrypted, which provides maximum performance on a secure network. However, this setting allows you to encrypt traffic during replication.

**Note:**  
Encrypting Replication  
Encrypting the replication stream will consume additional CPU resources and may limit the maximum bandwidth that can be achieved. During replication, the Delphix Engine will negotiate an SSL connection with its server peer to use TLS\_AES\_128\_GCM\_SHA256 as the cipher suite and TLSv1.3 as the protocol.
  - **Network connections:** Allows setting the number of underlying network connections that can be used by replication.
  - **Limiting bandwidth:** By default, replication will run at the maximum speed permitted by the underlying infrastructure. In some cases, particularly when a shared network is being used, replication can increase resource contention and may impact the performance of other operations. This option allows administrators to specify the maximum bandwidth that replication can consume.

- **Objects Being replicated:** Select the objects you wish to be replicated from the source engine to the target engine. In the right-hand column, under Objects Being Replicated, you can select the objects you want to replicate. Some selected objects may have dependencies – other objects that will be pulled into replication because they share data.

**Note:**

- This is not guaranteed to be the full set of dependent objects. The full set of objects and their dependents will be calculated at the time of replication.
  - You can not configure a Replication Profile without selecting an object and the last object from a Replication Profile can not be removed. If you need to remove the last object from the Replication Profile, you must delete that Replication Profile.
  - The object is removed from the replication target namespace only after a subsequent replication job is executed for the associated replication specification.
    - Remove the object from the specification on the source
    - Execute the replication specification
    - The object is removed as a part of the replication job. The object is not removed while modifying the replication specification. To add back the object, the entire object needs to be sent again.
1. When replicating a group, all dSources and VDBs currently in the group, or added to the group at a later time, will be included.
  2. If you select a Delphix Self-Service data template, all data containers created from that template will be included. Likewise, if you select a data container, its parent data template will be included.
  3. Regardless of whether you select a VDB individually or as part of a group, the parent dSource or VDB (and any parents in its lineage) are automatically included.
    - a. This is required because VDBs share data with their parent object.
    - b. In addition, any environments containing database instances used as part of a replicated dSource or VDB are included as well.
  4. When replicating individual VDBs, only those database instances and repositories required to represent the replicated VDBs are included. Other database instances that may be part of the environment, such as those for other VDBs, are not included.
  5. Non-data objects (Delphix users, roles, permissions, authorizations, policies, database configuration templates) that are associated with selected objects will be automatically included during replication. They will not be shown on the selection interface.

## Configuring the target Delphix engine

Additional configuration on the target engine is not needed. Replicated objects will appear in an alternate received replica (or namespace) that mirrors the original object layout.

To view replicated objects from the Delphix Engine:

1. Click System, then select Replication.
2. Look under Received Replicas. All replicated objects are read-only until the replica is failed over. For more information about managing replicas and how to activate a replica, see the topics [Replicas and Failover](#) and [Controlled Failover](#).

You can create and manage objects on the target server without affecting subsequent updates, though this can cause conflicts on failover that require additional time to resolve. For disaster recovery use cases, it is recommended to keep the target passive and not create any local objects. This will avoid conflicts and guarantee a smooth failover operation.

Multiple sources can replicate to the same target, allowing for the flexible geographical distribution of data. This is not a recommended practice for disaster recovery, because it increases the probability of conflicts on failover and may oversubscribe resources on the target if multiple replicas are failed over and there is insufficient infrastructure to support the combined workloads.

## Managing replicated objects

Once the failover process has completed the last step is to enable the objects on the Delphix Engine that received a replica. There are two major concepts:

1. **SSH Keys:** Public keys need to be re-published on the source, staging, and target environments for the replicated Delphix Engine, since the replication process does not automatically copy SSH keys.
2. **Enabling Replicated Objects:** Objects will need to be re-enabled once replication is complete. This ensures that replication has completed successfully and the configuration of each object is correct.

### SSH keys

If you were previously using a password-less SSH key exchange on your source and/or target environments, you may need to publish the now-primary engine's public key for continued functionality.

1. Click **Manage**.
2. Select **Environments**.
3. Select **any environment**.
4. Under **Environment Users**, click the **edit** icon () next to the defined user.
5. Click **View Public Key** to display the public key for the Delphix Engine.
6. Highlight the public key string (starts with "ssh-rsa") and copy the key to your clipboard (Ctrl+C in Windows).
7. On each source and target host within your defined environments, paste the public key into the environment user's authorized\_keys file, which is normally located in the user's ~/.ssh/ directory.

Once the public key has been copied to the hosts making up your environments, you are ready to enable the remaining objects.

### Enabling environments

In order to begin using the environments and related dSources and VDBs, the environments must first be started.

1. Login to the Delphix Management application.
2. Click **Manage**.
3. Select **Environments**.
4. Select an **environment** that you want to enable.
5. From the Actions menu (...) select **Enable**. This will initiate jobs that will refresh and enable the environment.
6. Repeat these steps for each environment that you want to enable.

### Enabling dSources

In order to again have actively syncing dSources, you must enable them.

1. Login to the Delphix Management application.
2. Click **Manage**.
3. Select **Datasets**.
4. Click the **dSource** you want to enable.
5. From the Actions menu (...) select **Enable**.
6. Click **Enable** to confirm.

### Enabling VDBs

The final step in the failover would be to enable any needed VDBs.

1. Login to the Delphix Management application.

2. Click **Manage**.
3. Select **Datasets**.
4. Click the **VDB** you want to enable.
5. Click the **Configuration** tab.
6. From the Actions menu (...) select **Enable**.
7. Click **Enable** to confirm that you want to enable the VDB.

At this time the failover is complete. All objects previously running on the previous source Delphix Engine should now be running off of the target Delphix Engine on which the objects were failed over.

## Controlled failover

This topic describes the process of failing over a replica. Objects stored in a replica are read-only, and failing over a replica moves the replicated objects to the live system. After a failover, all of the objects will appear in the system as if they had been created locally.

### Prerequisites

- A Delphix system that contains a replica is required.
- For an overview of what replicas are and what failover implies, see [Replicas and Failover](#).
- For more information on configuring replication, refer to the [Configuring Replication](#) topics.

### Procedure

1. Locate the replica to failover.
  - a. Click **System**.
  - b. Select **Replication**.  
In the **Received Replicas** section, you will see the list of replicas. Each replica has a default name that is the hostname of the source that sent the update. If you wish, you can customize these names. Each replica will list the databases and environments it contains.  
**Note:**  
If this replica is the result of a replication update, check to see whether or not the source Delphix appliance is still active. If it is still active, then disable any dSource or VDB that is part of the replica being failed over to ensure that only one instance is enabled. You can disable dSources and VDBs by selecting **Datasets**, finding the appropriate database, select **Disable**. After disabling the objects, navigate to **System > Replication** and click **Replicate Now** to get the most recent data to the target environment. If any scripts are accessing the engine, then you must repoint those scripts to the replication target environment to avoid VDBs from being started up in the old replication source environment.
2. Click **Failover** and a confirmation dialog will appear (see screenshot "failover-confirm"). To accept the default failover behavior, confirm the dialog.

This will pause while the replica is failed over.

3. When failover completes, the replica page will update.

4. Apply any configuration changes that are required to customize the objects for the system. This might include updating object states such as IP addresses, mount paths, or credentials. For more details, see the [Replicas and Failover](#) topic.
5. Enable the environments that were failed over.
  - a. Click **Manage**.
  - b. Select **Environments**. The environments that were failed over will be disabled.
  - c. From the Actions menu (...) select **Enable**.
6. Refresh any environments that were consolidated during failover.
  - a. Click the **Refresh** icon for each affected environment.
7. Enable the dSources and VDBs that were failed over.
  - a. Click **Manage**
  - b. Select **Datasets**.
  - c. Select the desired **database**.
8. From the Actions menu (...) select **Enable**.

 If the dSources and VDBs that were failed over belong to a plugin, depending on what version of the plugin existed on the target engine, the plugin may be in an inactive state. The plugin must be moved out of the inactive state before the object can be enabled. For more information see the [Delphix Engine Plugin Management](#) topic.

## After replication failover

Navigate to **System > Replication** and select the delete button to delete the replication specification.

A failover is similar to a migration operation for TDE-enabled vPDBs. If after the failover the original target hosts are still available, then the vPDB can be enabled on the failed over Delphix Engine without requiring additional manual steps. If the vPDB is to be restored to a different target host, then the same manual steps are required for migration, as the vPDB will now be located on a new target and thus needs the artifact directory, parent Keystore, and merged Keystore available.

## Uncontrolled failover

Before starting an uncontrolled failover, keep a note of the source and target engine's IP address and engine UUID. These details are available on the [Delphix server setup application](#)

### Uncontrolled failover procedure

1. On the source engine, create a replication spec for the dSources and VDBs, by clicking **Replicate now** to replicate these dSources/VDBs to the target engine.
2. To simulate a crash of the source engine, Power of the source engine.
3. On the target engine, click on **Failover**.  
At this point, the target engine will become active and the replicated environments/dSources/VDBs will be seen in the default namespace of the target engine.

The following sections describe the procedures to handle an Uncontrolled Failover for each data platform:

- [Oracle environment and data sources](#)
- [SAP ASE environment and data sources](#)
- [SQL server environment and data sources](#)

## Oracle environment and data sources

After an uncontrolled failover, for Oracle SI and RAC complete the following procedure:

1. Enable dSources and VDBs on the target engine. dSources will be enabled but the VDBs/vPDBs will fail.
2. To enable VDBs, shutdown the database instance using **SHUTDOWN ABORT**.
3. Remove all the mounts from the target environment with sudo privilege.
  - a. List all the mounts on the target environment using the `mount` command.
  - b. Run `umount -lf <Delphix-mount>` to remove the mounts. For example: `umount -lf /mnt/provision/VDBOMSR8A1718_FPX/datafile`
4. Remove all the stale oracle processes of the database instance using `kill -p <process id>`.
  - a. Run `ps -ef | grep "DATABASE INSTANCE"` to get all the running processes associated with the database instance. For example `ps -ef | grep VDBOMSR8A1718_FPX`. This command list all the running processes, e.g. **oracle 15236 9227 0 11:01 pts/0 00:00:00 grep --color=auto VDBOMSR8A1718\_FPX**
  - b. Run `kill -p <process id>` to kill all the running processes. For example: `kill -9 15236`
5. Now enabling VDBs and VPDBs will be successful.

## SAP ASE environment and data sources

After an uncontrolled failover has been triggered, on the target/staging host, the SAP ASE dSource/VDBs mounts, corresponding to the source engine, will still be present. This can be checked using the following command on the target host:

**mount | grep <source-engine-ip>**

These mounts will be mounted in the user-provided toolkit directory (Example */work*) and these would be of the form */ork/<Engine-UUID>-[staging/vdb]/[datafile/archive/temp]*. The following is an example for a dSource staging database mount */work/4201763f-2f8d-1c8f-381a-efb180b0328-staging-2/datafile*.

All the mounts will be using the source engine's UUID.

Attempting to 'Enable' or 'Start' the ASE dSources/VDBs on the target engine while the NFS mounts are in this stale state, will cause the jobs to hang or timeout or result in a job failure.

To clear off these stale mounts, one of the following options can be used:

### Manually unmount

1. Shutdown the concerned SAP ASE instances which host the dSource's staging database and VDBs.
2. List all the dSource/VDB mounts with a **mount | grep <source-engine-ip>**.
3. Remove all the mounts with a **umount -lf <Delphix-mount>** for example: **umount -lf /work/4201763f-2f8d-1c8f-381a-efb180b0328-staging-1/archive**, this might require sudo privileges. NOTE: Use the appropriate syntax for **umount** for your operating system. The above example is for Linux.
4. **Restart** the SAP ASE instances.

OR

### Reboot the target/staging host

Reboot the target/staging host corresponding to the concerned dSources/VDBs. This option is probably the cleanest way of clearing the source engine's leftover dSource/VDB mounts, but should only be used if the concerned target/staging host(s) do not host any other databases that are not part of the uncontrolled failover.

### Enabling Environments, dSources, and VDBs

1. Enable the source environment and then the target environment.
2. Enable the dSources and VDBs on the target engine.
3. Mounts will be moved to a new Delphix(Target Engine) and can be checked by using the following command: **mount | grep <target-engine-ip>** These mounts still use the source engine's UUID and not the target engine's UUID, but validated/manual syncs on dSources and refreshes/rewinds on VDB operations will be successful.

## SQL server environment and data sources

### Enabling environments and dSources

1. Enable the proxy(staging) environments followed by the source environments.
2. Enable dSources on the target engine.
3. Delete the staging database stale mounts from the connector directories. An example directory: **C:\ProgramFiles\Delphix\DelphixConnector\<Old Engine ID >-staging-<X>** where **X** is an arbitrary id representing the staging database.
4. Delete the staging database from the SQL instance on the proxy host using the following convention: **<Old Engine ID>-staging-<X>** where **X** is an arbitrary id representing the staging database.

### Enabling VDBs on the standalone host

1. Delete the VDB directories stale mounts from: **C:\ProgramFiles\Delphix\DelphixConnector\<Old Engine id>-vdb-<X>** where **X** is an arbitrary id representing the virtual database.
2. From the SQL instance delete VDB databases that are in recovery pending state.
3. Enable VDBs. New mounts will be created and a new engine ID will reflect on those mounts.

### Enabling VDBs on failover cluster as target

1. Once the source Engine is powered down login to **Failover cluster**.
2. Go to **Windows Administrative Tools** and select **Failover cluster manager**
3. On the left pane of the **Failover cluster manager** go to the **Roles**. As shown in the image below you will see the Failover cluster in the following state with the indicated status.

4. In order to fix the state go to the **Storage** section and select **Disks**. The **dlpx-XXXXXXXXXX** mounts attached to the Cluster Disk will be in offline states. These mounts will be equal to the total number of VDBs provisioned on that cluster as the target.

5. Right-click on the dlp mount, and select **Remove from SQL Server (Instance Name)**.

6. Click **Yes**.

In the **Assigned To** column, you will see **Available Storage**.

- Right-click on the **dplx mount** and click on **Remove**.

8. The dlpX mount will be deleted. Repeat the same process with other dlpX mounts assigned to **Available Storage**.
9. Under **Roles**, you would see that the **SQL Server service** is now in a **Failed** state.

In order to fix it right-click on the service and click **Stop Role**.

- Once the Stop role is executed properly, right-click on the **SQL cluster service** and click on **Start Role**.

- The SQL cluster service should now be online. Under the **Resources** tab the Storage, Server Name, Other Resources and Roles should have Online status. Ensure that the Disks and Nodes are also in an online state.

12. Make sure that both the nodes are in a healthy state.

## Replicas and failover

Replication recreates objects on the target system in a replica that preserves object relationships and naming on the target server without interfering with active objects on the system. Objects within a replica are read-only and disabled until a replica is failed over, at which point they can be activated. VDBs and dSources within a replica can be used as the source for provisioning new VDBs.

### Replicas

A replica contains a set of replicated objects. These objects are read-only and disabled while replication is ongoing. To view replicated objects, look under **namespace** in the CLI. Or in the GUI:

1. Click **System**.
2. Select **Replication**.
3. Under **Received replicas**, select the replica.

On this screen, you can browse the contents of replicas, as well as failover or delete individual replicas. As described in the [Replication overview](#) topic, databases (dSources and VDBs) and environments are included within the replica.

#### Deleting or failing over a replica

Deleting or failing over a replica will sever any link with the replication source. Subsequent incremental updates will fail, requiring the source to re-establish replication. Failover should only be triggered when no further updates from the source are possible, as in a disaster scenario.

Multiple replicas can exist on the system at the same time. Active objects can exist in the system alongside replicas without interfering with replication updates. You can also use VDBs and dSources within a replica as a source when provisioning. For more information, see [Provisioning from replicated data sources or VDBs](#)

### Failover and conflict resolution

To activate the objects in a replica, you must first fail over the replica. This will sever replication and move the objects to the live system, where they can be manipulated in the same fashion as other objects on the system.

Objects that are failing over can conflict with objects in the live system. One reason for conflicts is identical names. For example, Groups will conflict if the failing over Group has the same name as a Group in the live system, as will most other objects including Environments, dSources, and VDBs. By default, active objects with conflicting names will cause an error at the time of failover. The error message will indicate which object(s) have conflicting names.

For all other object types, because the replica objects are read-only, you must rename the active objects before the failover operation can complete successfully.

#### **Conflicting names**

Given that conflicting names prevent failover from succeeding, best practices in a disaster recovery situation are to leave the target system completely passive with no active objects until the time that failover is required.

#### **Conflicting plugins**

Due to the potential for plugin version incompatibilities, if any of your replicated objects are plugin-based, we highly recommend that you leave the target system completely passive with no active objects until the time that failover is required. For more information, see the [Delphix engine plugin management](#) page.

**⚠** When environments are consolidated, the Delphix engine maintains the existing environment configuration and privilege elevation profile; and merges replicated objects with them. Therefore, you must check and update the configured privilege elevation profiles when Environments are consolidated.

Once a replica is failed over, the objects are active but will be automatically disabled.

#### Manual conflict resolution

To resolve conflicts in Groups, you may either rename the conflicting group on the target replication engine or if the source replication engine is still available, rename on the source replication engine and send a replication update, before failover. For all other object types, because the replica objects are read-only, you must rename the active objects on the replication source engine and send a replication update before the failover operation can complete successfully.

#### Automatic conflict resolution

Starting with 6.0.2.0, most of the object conflicts can be resolved automatically. When you select "Automatically resolve object conflicts", replica objects like Groups will be renamed whereas objects like Environments will be merged and consolidated.

As of 6.0.5.0, the Automatic Conflict Resolution option will be chosen by default.

After automatic conflict resolution and successful failover, a report is presented with a list of objects that needed conflict resolution.

 ip-10-110-198-63-5 

 **Failover**

- Renamed GROUP from "Untitled" to "Untitled-ip-10-110-198-63-5"
- Consolidated UNIX\_HOST "172.16.102.163" with "172.16.102.163"
- Consolidated UNIX\_HOST "bbrac14" with "bbrac14"
- Consolidated UNIX\_HOST "172.16.101.163" with "172.16.101.163"
- Consolidated UNIX\_HOST "172.16.101.162" with "172.16.101.162"
- Consolidated UNIX\_HOST "cnrac11" with "cnrac11"
- Consolidated UNIX\_HOST "172.16.102.162" with "172.16.102.162"
- Consolidated WINDOWS\_HOST "10.110.244.248" with "10.110.244.248"
- Consolidated WINDOWS\_HOST "10.110.227.152" with "10.110.227.152"
- Consolidated WINDOWS\_HOST "10.110.156.45" with "10.110.156.45"
- Consolidated WINDOWS\_HOST "10.110.156.86" with "10.110.156.86"
- Consolidated WINDOWS\_CLUSTER "fc8uoqar268" with "fc8uoqar268"
- Consolidated ORACLE\_CLUSTER "bbrac1416" with "bbrac1416"
- Consolidated ORACLE\_CLUSTER "cnrac1113" with "cnrac1113"
- Consolidated ORACLE\_CLUSTER\_NODE "bbrac16" with "bbrac16"
- Consolidated ORACLE\_CLUSTER\_NODE "bbrac14" with "bbrac14"
- Consolidated ORACLE\_CLUSTER\_NODE "bbrac15" with "bbrac15"
- Consolidated ORACLE\_CLUSTER\_NODE "cnrac13" with "cnrac13"
- Consolidated ORACLE\_CLUSTER\_NODE "cnrac12" with "cnrac12"
- Consolidated ORACLE\_CLUSTER\_NODE "cnrac11" with "cnrac11"
- Consolidated WINDOWS\_CLUSTER\_NODE "10-110-156-86.ad.delphix.com" with "10-110-156-86.ad.delphix.com"
- Consolidated WINDOWS\_CLUSTER\_NODE "10-110-156-45.ad.delphix.com" with "10-110-156-45.ad.delphix.com"

**Replica Type**

Replication

**Replicated Objects**

No replicated objects

**Description** 

**Environments**

No replicated environments

Automatic conflict resolution is not supported for objects like dSources and VDBs.

### Enabling databases and environments

Objects may refer to states (IP addresses, mount paths, etc) that differ between the source and target system. Because of this, all databases and objects within a replica automatically start in the disabled state after a failover. This allows the administrator to alter configuration prior to enabling databases and environments, without the system inadvertently connecting to invalid systems.

After failover is complete, you must explicitly enable all dSources, VDBs, and environments. If you need to change any configuration for the target environment, you can do so prior to enabling the objects. In the event that a failing-over environment is consolidated with a live system environment, it must be refreshed before all of it's databases can be used.

## Provisioning from replicated data sources or VDBs

This topic describes how to provision from a replicated dSource or VDB. The process for provisioning from replicated objects is the same as the typical VDB provisioning process except for the need to first select the namespace containing the replicated object.

### Prerequisites

You must have done the following:

- replicated a dSource or a VDB to the target host, as described in [Replication overview](#)
- added a compatible target environment on the target host as described in [Provisioning Oracle VDBs: an overview](#)
- installed on the target host any App Data plugin which the replicated objects depend on

### Procedure

1. Login to the **Delphix Management** application for the target host.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **replica** that contains the dSource or VDB to be provisioned.
5. The provisioning process is now identical to the process for provisioning standard objects.

 If the dSource or VDB belongs to a plugin, the plugin must exist on the target engine to be successfully provisioned. The target's plugin's version must also be equal to or higher than the source's plugin's version. For more information see the [Delphix engine plugin management](#) topic.

### Post-requisites

Once the provisioning job has started, the user interface will automatically display the new VDB in the live system.

## Replication user interface

The replication user interface helps users manage replication on both the source and the target. Replication consists of a profile-replica pair. You can view and edit the replication profile on the source engine, and view the replica on the target engine.

### Sources for replication

The **Replication Profiles** section provides you with several configuration options for your replication profiles. This makes it possible to replicate objects from a single source to multiple targets. Each profile defines the set of data objects and the associated configuration between a single source and target.

### Targets for replication

The **Received Replicas** section shows the set of all objects in the replica and allows you to initiate failover.

### Canceling a replication job

You must cancel the replication job at the source engine. Canceling the replication job at the target engine results in the re-starting of the receiving job at the target engine. If the source engine is down, then you can cancel the replication job at the target engine. If you re-start the source engine where the replication job was previously running, the source engine will attempt to restart the replication send job.

## Replication UI

The Replication UI consists of the following sections.

### Replication profiles

The screenshot and descriptions below illustrate the capabilities in the **Replication profiles** section.

The screenshot displays the 'Replication Profiles' section of the user interface. It features a sidebar on the left with a 'Replication Profiles' header and a '+1' button (1) for creating a new profile. Below this is a list of profiles, with 'My Profile' selected and highlighted (2). At the bottom of the sidebar is the 'Received Replicas' section (3), which currently shows no replicas. The main content area displays the details for 'My Profile', including a 'New Replication Profile' status bar (4) with a 'Next Scheduled' time of Jul 27, 2021 12:30:00 PM. The profile details are organized into sections: 'DESCRIPTION' (My first replication profile), 'TARGET ENGINE' (test.delphix.com), 'AUTOMATIC REPLICATION' (Every 1 Day(s) at 12:00 AM) (5), and 'TRAFFIC OPTIONS' (Encrypted). The 'REPLICATION TYPE AND OBJECTS' section (6) shows the profile type as 'Replication' and the objects being replicated as 'Entire Delphix Engine'. A 'Replicate Now' button (7) is located in the top right corner, and icons for editing and deleting the profile (8) are also present.

- 1. Create profile button**  
It allows you to configure a Replication Profile.
- 2. Replication profiles list**  
Provides a list of existing replication profiles. Click a profile in this list to view its details.

3. **Received replicas list**  
Provides a list of all existing replicas on this Delphix Engine. Click a replica in this list to view its details.
4. **Status box**  
Shows the replication status of the selected profile. This includes the result of the most recent or current replication event and statistics for the replication run (i.e. data transferred, duration, average throughput, etc.).
5. **Configuration options**  
Additional configuration options for the selected replication profile.  
*Description:* Free text field for a profile description.  
*Target Engine:* The Delphix engine on the receiving end of this replication pair.  
*Automatic Replication:* If enabled, shows the frequency and time that regular replication will be run.  
*Traffic Options:* Summarizes the traffic options with which this profile has been configured.
6. **Objection selection tree**  
Shows all of the objects, such as groups, dSources, VDBs, and Self-service (JetStream) data layouts, that you have selected for replication in this replication profile. Selecting **Entire Delphix Engine** will cause all objects on the engine to be replicated, and thus the tree is collapsed.
7. **Replicate now button**  
Begins the replication process
8. **Delete button**  
Allows you to delete the current profile.

## Received replicas

The screenshot and descriptions below provide more details of the functionality of this section.

1. **Status box**  
Similar to the **Replication profile** status box, this shows the most up-to-date status information for the replica on the target
2. **Replicated environments**  
Replicating a dSource or VDB will automatically replicate any environments associated with those objects. For more information, see [Replication overview](#)
3. **Replicated objects tree**  
A read-only view of the objects in this replica.
4. **Failover button**  
Initiates a failover for this replica

### 5. Delete button

Deletes this Replica on the target. This does not have an effect on the corresponding profile on the source engine.

## Create new replication profile wizard

Perform the following steps to create a new replication profile.

1. Login to the **Delphix Management** application.
2. Navigate to **System > Replication**.

3. Next to **Replication Profiles**, Click the **plus** icon. The **Add Replication Profile** wizard screen appears.
4. Enter the **Name** of the replication profile and an optional **Description**, and click **Next**.
5. To specify the **Object**, select the **Profile Type** as **Replication Profile** and select from the **Objects Being Replicated** to a target engine. Click **Next**.

#### Note:

##### Selected Objects

- a. Some selected objects may have dependencies – other objects that will be pulled into replication because they share data. Objects that will be replicated are confirmed with a blue chain link icon.
  - i. **Note that this is not guaranteed to be the full set of dependent objects, but rather is the best guess. The full set of objects and their dependents will be calculated at the time of replication.**
- b. When selecting objects, you can select the entire server (**Entire Delphix Engine**) or a set of groups, dSources, VDBs, and Jet Stream data layouts.
- c. When replicating a group, all dSources and VDBs currently in the group, or added to the group at a later time, will be included.
- d. If you select a Delphix Self-Service data template, all data containers created from that template will be included. Likewise, if you select a data container, its parent data template will be included.
- e. If you select the entire server, all groups and Delphix Self-Service objects will be included.
- f. Regardless of whether you select a VDB individually or as part of a group, the parent dSource or VDB (and any parents in its lineage) are automatically included. This is required because VDBs share data with their parent object. In addition, any environments containing database instances used as part of a replicated dSource or VDB are included as well.

- g. When replicating individual VDBs, only those database instances and repositories required to represent the replicated VDBs are included. Other database instances that may be part of the environment, such as those for other VDBs, are not included.
  - h. Non-data objects (Delphix users, roles, permissions, authorizations, policies, database configuration templates) that are associated with selected objects will be automatically included during replication. They will not be shown on the selection interface.
6. For **Target Engine**, enter the **hostname** or **IP address** for the target Delphix Engine. Enter the **username** and **password** of a user who has Delphix Admin-level credentials on the target Delphix Engine. If the username or password changes on the target Delphix Engine, you must update these settings on the source Delphix Engine. Click **Next**.
7. By default, automatic replication is disabled and you must trigger replication updates manually. To **Schedule** automatic replication, click the **Enabled** checkbox. In the **Automatic Replication** field, enter the frequency and starting time for replication updates to the target Delphix Engine. Once you have entered and saved your replication settings, you will also see an option to trigger replication immediately with the **Replicate Now** button. Under **Traffic Options**, select whether you want to **Encrypt** traffic or **Limit bandwidth** during replication updates. Click **Next**.
8. The final summary tab will enable you to review your configurations. Click the **Back** button to go back and to change any of the configurations or click **Submit** to complete the wizard.

## Viewing and editing an existing replication profile

Perform the following steps to view and edit existing replicas.

1. Login to the **Delphix Management** application.
2. Navigate to **System > Replication**.
3. Under the **Received Replicas** section, select a replica.
4. You can edit the **Name** and **Description** fields. All other fields are view-only.

Perform the following steps to edit the fields.

1. Click the **pencil** icon next to the corresponding field or group of fields to edit the fields.
2. To save the edits and/or selections, click the **Checkmark** icon.
3. To cancel the edits and/or selections, click the **cross** icon.

## Selective data distribution

These topics describe concepts and procedures for using Selective Data Distribution (SDD) to replicate data from one Delphix Engine to another.

- [Support matrix for selective data distribution](#)
- [Selective data distribution overview](#)
- [Selective data distribution use Cases](#)
- [Selective data distribution user Interface](#)
- [Configuring selective data distribution](#)
- [Selective data distribution and failover](#)

## Support matrix for selective data distribution

SDD is supported across all environments supported by each data source. Refer to the support matrix for each data source below.

- [Oracle Matrix](#)
- [SQL Server Matrix](#)
- [SAP ASE Matrix](#)
- [Db2 Matrix](#)
- [EBS Matrix](#)
- [HANA Matrix](#)
- [PostgreSQL Matrix](#)

## Selective data distribution overview

The selective data distribution technology permits the distribution of masked data between Delphix Engines without bringing over the unmasked parent source. These engines must be the identical versions of the Delphix Data as a Service Engine with the Delphix Masking Engine. Otherwise, they can be asymmetric in terms of engine configuration. You can provision VDBs from distributed masked objects, allowing for the geographical distribution of data and remote provisioning.

You can run selective data distribution ad hoc, but it is typically run according to a predefined schedule. After the initial update, each subsequent update sends only the changes incurred since the previous update. Selective data distribution does not provide synchronous semantics, meaning that the data distributed to the target is only as current as of the most recent update.

## Selective data distribution features

As virtual appliances, you can backup, restore, replicate, and migrate data objects between Delphix Engines using features of VMWare and the underlying storage infrastructure. In addition to the replication capabilities provided by this infrastructure, selective data distribution permits the distribution of masked data between Delphix Engines. The sources received on a target Delphix Engine do not include the original parent source, thereby making the original source inaccessible from the target.

Selective data distribution is configured on the source Delphix Engine. It first copies a subset of masked VDBs to a target Delphix Engine, then sends incremental updates either manually or according to a schedule. As illustrated below, sensitive data from the Production Data Center is brought into Delphix as a dSource. The Masking Engine then masks the dSource data as a VDB. Synchronously, DxFs redacts the sensitive data within that dSource before sending it across into the Non-Production datacenter using Delphix Replication. Using SDD capability, sensitive data is never exposed because it is protected both at the dSource and VDB layers.

You can use replicated masked VDBs to provision new VDBs on the target Delphix Engine. The provisioned VDBs contain the data in their masked parent and are therefore also considered masked. You can refresh these VDBs to snapshots sent as part of an incremental replication update, as long as you do not destroy the parent object on the replication source. For more information, see [Provisioning from a Replicated Data Sources or VDBs](#).

During replication, replicated masked VDBs are maintained in an alternate replica and are not active on the target side. The failover of a selective data distribution replica is not supported.

## Selective data distribution details

When you select masked objects for selective data distribution, the engine will automatically include any dependencies, such as environments, associated with the VDB. The parent dSource and any parent VDBs are not included automatically. The data associated with parent objects are selectively included for disk space efficiency, but data in the parent dSource and VDBs that the masked VDB does not need are excluded.

During replication, the Delphix Engine will negotiate an SSL connection with its server peer to use SSL\_RSA\_WITH\_RC4\_128\_MD5 as the cipher suite, and TLSv1 as the protocol.

Only database objects and their dependencies are copied as part of a selective data distribution operation, including:

- Masked VDBs
- Environments
- Environment configuration (users, database instances, and installations)

The following objects are not copied as part of a selective data distribution operation:

- Parent dSources of masked VDBs - The storage blocks for non-sensitive dSource data are sent from the source to the target replication host. This storage is displayed under Held Space, for more information see [An Overview of Held Space](#).
- Groups of the parent dSources
- Users and roles
- Policies
- VDB (init.ora) configuration templates
- Events and faults
- Job history
- System services settings, such as SMTP

## Resumable selective data distribution

A single selective data distribution instance can fail for a number of environmental and internal reasons. However, using the Resume feature, you can restart selective data distribution from an intermediate point; no data is retransmitted. Selective data distribution is resumable across machine reboot, stack restart, and network partitions. The resumable replication feature is fully automated and does not require or allow any user intervention.

For example, you can resume a large, time-consuming initial distribution or incremental update after it is interrupted. Suppose a selective data distribution profile has already been configured from a source to a target. A large, full send from the source begins that is expected to take weeks to complete. Halfway through, a power outage at the data center that houses the source causes the source machine to go down and only come back up after a few hours. On startup, the source will detect that a selective data distribution was ongoing, automatically re-contact the target, and resume the distribution where it left off. In the user interface (UI) on the source, the same selective data distribution send job will appear as active and continue to update its progress. However, in the UI of the target, a new distribution receives job will appear, although it will track its progress as a percentage of the entire replication.

Selective data distribution will not resume after failures that leave the source and target connected. For example, if a storage failure on the target, such as an out-of-space error, causes a distribution to fail, then the source and target remain connected. As a result, the Engine will discard state data associated with the failed Replication operation.

## Selective data distribution restrictions

- Only masked VDBs can be added to a selective data distribution spec. You cannot add dSources, groups, or the entire domain.
- Only masked VDBs with a Snapshot Policy of None should be added to a selective data distribution spec.
- Unmasked VDBs cannot be added to a selective data distribution spec.
- VDBs that undergo selective data distribution and their children cannot be selectively redistributed to another target.
- You cannot go to the target engine and create a selective data distribution spec that includes VDBs that are present because of selective data distribution. However, you can replicate this data using a traditional replication spec.

Best practices for using Selective Data Distribution are described in the [Selective Data Distribution Best Practices](#) knowledge base article.

## Selective data distribution supported platforms

Selective Data Distribution supports the following platforms:

- Oracle
- Microsoft SQL Server
- SAP ASE (Sybase)

- Db2

## Selective data distribution use cases

Selective data distribution is a flexible tool that allows you to move dSources and virtual databases (VDBs) between Delphix Engines. Selective data distribution relies on the replication infrastructure to transmit masked data, as such selectively distributed data has much of the same capabilities as replicated data. These topics describe several different use cases for selective data distribution.

### Geographically distributed development

The Delphix Engine allows you to provision VDBs from distributed dSources and VDBs, as described in [Provisioning from Replicated Data Sources or VDBs](#). This allows dSources that are linked in a single central location to be geographically distributed so that developers can provision VDBs remotely without having to sync from the source database in multiple locations. Selective distribution ensures that masked VDBs are sent to the target without transmitting the original unmasked source. As such, the original unmasked source will not be accessible on the target.

Selective data distribution does not support failover. In this environment, the link between the source and the target is never broken, except when remote VDBs need to be preserved. You can refresh remote VDBs as long as the parent objects continue to exist on the source. If they are deleted, then remote VDBs will continue to function but cannot be refreshed.

Because there is no failover, this technology can support more complex topologies such as 1-to-many and many-to-1. Chained distribution (replicating from Site A -> Site B -> Site C) is not supported.

## Best practices

For geographical distribution, follow these best practices:

- Because each replication stream induces load on the source system:
  - Minimize the number of simultaneous replication updates
  - If possible, avoid heavy VDB workloads on the source
- On the target, the provision only from sources that are effectively permanent. If a source is deleted remote VDBs can no longer be refreshed.
- Provision additional storage capacity on the target
  - Remotely provisioned VDBs can consume shared storage on the target even when the parent is deleted on the source

## Migration

You cannot use selective data distribution for data migration. Full replication is needed for data migration.

## Selective data distribution user interface

### Sources for selective data distribution

The **Replication Profile** section continues to handle Replication functions, but also allows for the configuration of **Selective Data Distribution (SDD)** profiles. This makes it possible to distribute objects from a single source to multiple targets. Each profile defines the set of data objects and the associated configuration between a single source and target.

### Replication/selective data distribution section

This section is used to illustrate the capabilities in the **SDD Profiles** section. From the Delphix Management portal, navigate to **System > Replication**.

Select the plus icon to add a profile, this will open a new window for configurations. Below the **Replication Profiles** header and the plus icon is a list of existing Replication Profiles and SDD profiles. Select a profile in this list to view its details.

The **Received Replicas List** shows all replicas received to this Delphix Engine, including normal Replication and SDD replicas. Click a **replica** in this list to view its details.

A **Status Box** appears when a profile is selected from the list that shows the distribution status of the selected profile. This includes the result of the most recent or current distribution event and statistics for the distribution run, such as data transferred, duration, and average throughput. The **Profile Type** shows the type of the selected profile or replica.

There are several configuration options available for the selected profile or replica listed below the Profile Type. These sections, in addition to the profile name itself, can be modified by selecting the pencil icon.

- Description – Free text description of the profile
- Target Engine – The Delphix Engine on the receiving end of this data distribution pair
- Automatic Replication – If enabled, shows the frequency and time that regular distribution will be run
- Traffic Options – Summarizes the traffic options with which this profile has been configured

The **Objects Being Replicated** shows all of the masked objects selected for distribution in this SDD profile. The **Replicate Now** button initiates the distribution process and the **bin icon** to the left allows for current profile deletion.

The screenshot displays the 'Replication Profiles' section in the DELPHIX MANAGEMENT console. The profile 'sdd' is selected, and its configuration is shown in a right-hand pane. A 'Replicate Now' button is visible in the top right corner. The configuration details are as follows:

- Last Replication Successful:** 0:01:04 | 1.71GB | 46.99MB/s. Last Successful Replication Jul 9, 2020 4:27:18 PM (2 minutes ago).
- Profile Type:** Selective Data Distribution
- Description:** (Editable)
- Target Engine:** 6021.dlpxdc.co (Editable)
- Automatic Replication:** Disabled (Editable)
- Traffic Options:** None (Editable)
- Objects Being Replicated:**
  - dSources and VDBs
    - Untitled
      - VPDB\_8NQ (Source: PDB1. Masked parent: VPDB\_8NQ)
  - = will be replicated

Below the configuration pane, there is a 'Received Replicas' section with a sub-section for 'ip-10-110-227-8-1'.

## Create new profile

1. In the left-hand navigation section, click the **+** icon.
2. Enter the **name** of the SDD profile and an optional **description**.
3. For **Type**, select **Selective Data Distribution**.
4. For **Target Engine**, enter the **hostname** or **IP address** for the target Delphix Engine.
5. Enter the **username** and **password** of a user who has Delphix Admin-level credentials on the target Delphix Engine. If the username and password change on the target Delphix Engine, these settings must be updated on the source Delphix Engine.
6. Automatic replication is disabled by default, which means the distribution updates must be triggered manually via the **Replicate Now** button. To enable automatic distribution, click the **Enabled** checkbox.
7. In the **Automatic Replication** field (if enabled), enter the **Frequency** and **Starting Time** for distribution updates to the target Delphix Engine.
 

**Note:** Automatic replication uses Quartz for scheduling. Starting with Delphix version 4.2, the Quartz-formatted string is editable via the **Advanced** option. An example **Cron String** would be seen as: `0 0 0 *`
8. Under **Traffic Options**, select to **Encrypt** traffic or **Limit bandwidth** during distribution updates.
9. In the right-hand column under **Objects Being Replicated**, select the **boxes** next to the objects to distribute. Only masked VDBs can be used and multiple masked VDBs cannot be added to the same profile.
10. Click **Create Profile** to submit the new profile. This saves the SDD profile details. Leaving the **Create** page prior to submitting the profile will result in the draft being discarded.

## Configuring selective data distribution

This topic describes how to configure Selective Data Distribution between Delphix Engines. Selective data distribution relies on the replication infrastructure to transmit masked data, as such configuring selective data distribution is similar to configuring replication.

### Prerequisites

- The replication target can be on the same or newer version than the replication source. Starting 6.0.10.0, replication operation can not go beyond engine versions released more than 12 months apart. For more information, see [Replication Overview](#).
- The target Delphix Engine must be reachable from the source engine.
- The target Delphix Engine must have sufficient free storage to receive the replicated data.
- The user must have administrative privileges on the source and the target engines.

### Configuring the network

Replication and selective data distribution operate using a private network protocol between two Delphix Engines. Apart from standard network considerations for performance, no additional configuration is required for replication. Replication and selective data distribution can run over dedicated networks by configuring routing to direct traffic destined for the target IP address over a specific interface. The selective data distribution process can recover from transient network outages, but extended outages may cause the process to start from the previous update.

The selective data distribution network protocol uses TCP port 8415. If there is a firewall between the source and target that is blocking this port, then there are two possible solutions:

- Enable port 8415 on the firewall in order to allow connections to this port from the source to the target.
- Selective data distribution can connect through a SOCKS proxy if one exists. Configure the SOCKS proxy address and port by connecting to the command-line interface (CLI) as a system administrator and navigating to "service proxy" to update the socks configuration. Example:

```
dlpx-engine> service proxy
dlpx-engine service proxy> update
dlpx-engine service proxy update *> set socks.enabled=true
dlpx-engine service proxy update *> set socks.host=10.2.3.4
dlpx-engine service proxy update *> set socks.username=someuser
dlpx-engine service proxy update *> set socks.password=somepassword
dlpx-engine service proxy update *> commit
dlpx-engine service proxy> get
  type: ProxyService
  https:
    type: ProxyConfiguration
    enabled: false
    host: (unset)
    password: (unset)
    port: 8080
    username: (unset)
  socks:
    type: ProxyConfiguration
    enabled: true
```

```

host: 10.2.3.4
password: *****
port: 1080
username: someuser

```

Note that SOCKS port 1080 is used by default, but you can override it.

## Configuring the source Delphix engine

1. On the source Delphix Engine, click **System**.
2. Select **Replication**.
3. In the left-hand navigation section, click **Create Profile**.
4. Enter the **name** of the replication profile and an optional **description**.
5. Select type **Selective Data Distribution**.
6. For **Target Engine**, enter the **hostname** or **IP address** for the target Delphix Engine.
7. Enter the **username** and **password** of a user who has Delphix Admin-level credentials on the target Delphix Engine. If the username and password change on the target Delphix Engine, you must update these settings on the source Delphix Engine.
8. By default, automatic replication is disabled, meaning that you must trigger replication updates manually. To enable automatic replication, click the **Enabled** checkbox.
9. In the **Automatic Replication** field, enter the **Frequency** and **Starting Time** for replication updates to the target Delphix Engine. Once you have entered and saved your replication settings, you will also see an option to trigger replication immediately with the **Replicate Now** button.

**Note:**

Quartz scheduling Automatic replication uses Quartz for scheduling. Starting with Delphix version 4.2, the Quartz-formatted string is editable via the **Advanced** option.

10. Under **Traffic Options**, select whether you want to **Encrypt** traffic or **Limit bandwidth** during replication updates. **Note:**

**Encrypting Traffic** By default, replication streams are sent unencrypted. This provides maximum performance on a secure network. If the network is insecure, encryption can be enabled. Note that encrypting the replication stream will consume additional CPU resources and may limit the maximum bandwidth that can be achieved.

**Note:**

**Limiting Bandwidth** By default, replication will run at the maximum speed permitted by the underlying infrastructure. In some cases, particularly when a shared network is being used, replication can increase resource contention and may impact the performance of other operations. This option allows you to specify the maximum bandwidth that replication can consume.

11. In the right-hand column, under **Objects Being Replicated**, click the **checkboxes** next to the objects you want to replicate.

**Note:**

**Selected Objects**

- a. You can only select masked VDBs for selective data distribution.
  - b. The parent dSource or VDB (and any parents in its lineage) are NOT automatically included. Some of the data from the parent may be included for disk space optimization. In addition, any environments containing database instances used as part of a replicated VDB are included as well.
  - c. When replicating individual VDBs, only those database instances and repositories required to represent the replicated VDBs are included. Other database instances that may be part of the environment, such as those for other VDBs, are not included.
12. Click **Create Profile** to submit the new profile. This saves the replication profile details. If you leave the **Create** page prior to submitting the profile, the draft replication profile will be discarded.

**Note:**

Configuring Replication and Multiple Target Engines through the CLI

You can also configure replication on the Source Delphix Engine by using the replication spec in the command line interface. For more information, see the topics under [CLI Cookbook: Replication](#).

**Note:**

[Enabling Configuration of Multiple Replication Profile](#)

Learn how to configure and use functionality for multiple replication profiles on the source using the replication profiles in the [Replication User Interface](#).

## Configuring the target Delphix engine

No additional configuration on the target is needed. Selectively distributed objects will appear in an alternate replica that mirrors the original object layout. To view these replicas:

1. Click **System**.
2. Select **Replication**.
3. Review items listed under **Received Replicas**.

Alternatively, you can view replicas under **namespace** in the command-line interface (CLI). All replicated objects are read-only. For more information about managing replicas, see [Selective Data Distribution and Failover](#).

Multiple sources can replicate to the same target, allowing for the flexible geographical distribution of data. You can create and manage objects on the target server without affecting subsequent updates. However, you cannot use selective data distribution for disaster recovery.

## Selective data distribution and failover

Selective data distribution recreates objects on the target system in a replica that preserves the object relationships and naming on the target server without interfering with active objects on the system. Objects within a replica are read-only and disabled. They cannot be failed over. However, you can use virtual databases (VDBs) within a replica as the source for provisioning new VDBs.

### Replicas

A replica contains a set of replicated objects. These objects are read-only and disabled while replication is ongoing. To view replicated objects:

1. Click **System**.
2. Select **Replication**.
3. Under **Received Replicas**, select the replica. On this screen, you can browse the contents of replicas or delete individual replicas. As described in the [Selective Data Distribution Overview](#), VDBs and environments are included within the replica.

You can also view replicated objects under **namespace** in the command-line interface (CLI).

Deleting a replica will sever the link with the replication source. Subsequent incremental updates will fail, requiring the source to re-establish replication.

Multiple replicas can exist on the system at the same time. Active objects can exist in the system alongside replicas without interfering with replication updates. VDBs within a replica can also be used as a source when provisioning. For more information, see [Provisioning from Replicated Data Sources or VDBs](#).

### Failover

Selective data distribution does not support the failover of replicas.

## Delphix self-service

### Delphix self-service

Delphix Self-Service eliminates data related bottlenecks by extending virtual data on demand to application development teams as a self-service.

## Delphix self-service admin guide

This section covers the following topics:

- [Getting started with delphix self-service](#)
- [Delphix self-service concepts](#)
- [Navigating the Delphix self-service admin interface](#)
- [Understanding data templates](#)
- [Understanding how to manage data template details](#)
- [Understanding data containers](#)
- [Delphix self-service data container activities](#)
- [Using masked data sources with Delphix self-service](#)
- [Understanding Delphix self-service user management](#)
- [Working with multiple container owners](#)
- [Understanding bookmarks](#)
- [Understanding Delphix self-service usage management](#)

## Getting started with delphix self-service

### Welcome to Delphix self-service

The Delphix Engine has greatly improved the speed at which end users can get the data that they need. While end-users reap the benefits, they do not typically interact with the Delphix Engine directly, nor are they necessarily even aware that they are using it. End users most commonly file tickets for data management operations and wait for the tickets to be serviced by their IT organization. Delphix data management workflows allow database administrators (DBAs) to respond to these tickets much more quickly and reliably, but DBAs are often overloaded, and resolving high-priority issues takes precedence over requests from users. Requiring interactions between users and IT for every data operation is inefficient and can lead to unwanted delays.

The goal of Delphix Self-Service is to create a clear separation of IT infrastructure and data management. As with the current Delphix Engine, IT administrators and DBAs continue to control decisions about how resources such as virtual databases (VDBs) and vFiles are allocated. However, with Delphix Self-Service, administrators can also assign these resources directly to a user. A user has the ability to control what data their container presents, even though the details of the physical resources are hidden from them. This separation of roles empowers Delphix Self-Service users to get the data they need, when they need it while providing administrators with the controls to ensure resources are accounted for appropriately.

### User roles and permissions

Delphix Self-Service has two types of users:

#### Admin user

Admin users have full access to all report data and can configure Delphix Self-Service, additionally, they can:

- use the Delphix Engine to add/delete users
- change tunable settings
- add/delete tags
- create and assign data templates and containers

#### Data user

Data users have access to production data provided in a data container. The data container provides these users with a playground in which to work with data using the **Self-Service Toolbar**.

### Login

1. Access Delphix Self-Service by opening a web browser and using the **IP address** or **DNS qualified hostname**.
2. Login with the **Delphix Admin User ID** and **Password** provided for you.
3. Upon successful login, you should be able to click on your username at the top right corner and select a Self-service view from the dropdown menu. This will open the Delphix Self-Service interface.

## Delphix self-service concepts

### Data sources

A data source can be a database, an application, or a set of unstructured files. Delphix administrators configure the Delphix Engine to link to data sources, which pulls in the data of these sources. The Delphix Engine will periodically pull in new changes to the data, based on a specific policy. This, in turn, begins building a custom timeline for each data source. Additionally, the Delphix Engine can rapidly provision new data sources that are space-efficient copies, allowing users to work in parallel without impacting each other.

### Data templates

Data templates are the backbone of data containers. They are created by the Delphix administrator and consist of the data sources that users need in order to manage their data playground and their testing and/or development environments. Data templates serve as the parent for a set of data containers that the administrator assigns to users. Additionally, data templates enforce the boundaries for how data is shared. Data can only be shared directly with other users whose containers were created from the same parent data template.

### Data containers

A data container allows data users to access and manage their data in powerful ways. Their data can consist of application binaries, supporting information, and even the entire database(s) that underlie it.

A data container allows users to:

- Undo any changes to their application data in seconds or minutes
- Have immediate access to any version of their data over the course of their project
- Share their data with other people on their team, without needing to relinquish control of their own container
- Refresh their data from production data without waiting for an overworked DBA

A data container consists of one or more data sources, such as databases, application binaries, or other application data. The user controls the data made available by these data sources. Just like data sources in a template, changes that the user makes will be tracked, providing the user with their own data history.

The **Data Container Interface** lets users view the details and status of their data container and its associated data sources, as well as manipulating which data is in those sources. The **Data Container Interface** includes a section called the **Data Container Report Panel**, which displays details about each source, including the connection information needed to access it – for example, the java database connectivity (JDBC) string for a database. This connection of information is persistent and stable for the life of the data container, regardless of what data the resources are hosting.

### Delphix Self-Service Data Flow

The Delphix Self-Service data flow diagram below demonstrates how a Delphix Self-Service data user accesses data sources. Data sources are connected to a Delphix Engine, which is controlled by the Delphix administrator. The Delphix administrator will connect all data sources that developers and quality assurance (QA) teams need to a data template. This data template acts as a parent source to create the data containers that the administrator will assign to data users. Data sources flow from the Delphix Engine into a data template and downstream into a data container, where a data user or users will use the data sources to complete tasks. The data container acts as a self-contained testing environment and playground for the data user. Additionally, data users are able to set, bookmark, and share data points in their container with other data users of other data containers, as long as all the data containers were created from the same parent data template.

## Navigating the Delphix self-service admin interface

The following screenshots provide a roadmap for how to navigate the primary screens and places a user will go within the Delphix Self-Service application. The application includes screens such as the **Management Overview**, **Data Platform Management**, **Users and Permissions**, and **Data User Management**.

### Overview screen

The **Overview** screen is the homepage for Delphix Self-Service. To reach this page from the Management application as an admin user, select **Self-Service** in the user login drop-down.

Name	Containers	Role	Email Address
admin	2	Engine Admin	webtester1@smtptest.com
batgirl	1	Self-Service User	batgirl@mycompany.com
tom	1	Self-Service User	tom@abc.com

### Data management overview page

On this page, you can:

1. You can delete one or more templates at one time by selecting the checkboxes and clicking the **Delete** button.
  - a. You cannot delete replicated templates or templates that have containers.
2. From this column, you can see which replica the template belongs to if it is a replicated template. You can sort by this column and see all templates from the same replica.
  - a. This column lists replica names, not replication sources. You can view a list of replicas in the Management application at **System > Replication > Received Replicas**.
3. The number of containers associated with the template.
4. Shows the last time the template was updated.
5. Create a new data template.

### Users screen

By selecting the Users Button you can view users, whom you can then assign to data containers that you create from existing data templates.

Name	Containers	Role	Email Address
admin	2	Engine Admin	webtester1@smtptest.com
batgirl	1	Self-Service User	batgirl@mycompany.com
tom	1	Self-Service User	tom@abc.com

1. List of all configured users. You can click on a user to see their details, such as what containers they are assigned to.
2. The number of containers assigned to the user.
3. The Role column indicates whether a user is a **Jet Stream Only** user or a **Delphix Admin**.
4. Lists the associated email address for the user.
5. Select this link to add a new user or manage users.

### Data template management

The **Data Template Management** page contains a view panel of 6 tiles on the left-hand side of the screen. Each tile reports on a variety of useful information, such as user activity, data sources, data capacity, specific details about data containers, and data templates. They also help you navigate to areas where you can complete specific tasks, such as creating a new template or container, working with data timeflows, assigning users to containers, and bookmarking important points in time.

### User roles in admin App

To add or manage user roles and permissions, select the **Add or manage users** link from the **Users Overview** screen.

The **Users** screen in the Management application will open. From this screen, you can add a new user, edit a user, suspend a user, or delete a user.

Selecting the **+** icon opens the **Add User** window. Use this window to add a user and select the user role and permissions.

### Data operations interface for Delphix administrators

The **Overview** page is the only interface to which Delphix Self-Service data users have access and with which they interact. The user interface is the environment in which a data user works with data in an assigned data container, using data sources from a data template.

As shown below, the **Data Operations** screen contains a list of available templates. Select a template to view details.

The following screen allows users to complete tasks using self-service operations.

For more details about how to use this interface, refer to the [Delphix Self-Service Data User Guide](#).

### Administrator settings

You can open the **Administrator Settings** dialog from the user drop-down menu. Here you can edit various settings that apply globally to all Delphix Self-Service users.

### Default bookmark expiration

You can set a value that controls the default expiration time, in days, for Bookmarks. This setting only applies to new bookmarks that are created through the Delphix Self-Service application, not the CLI or API. Note that this only controls the default selection; users can still disable expiration or pick a different date for a specific bookmark if they wish. This setting is disabled by default.

### Automatic retry for data operations

To make operations on data containers more robust, Delphix Self-Service supports automatically retrying failed sources during data operations. You can specify a maximum number of retry attempts so that if an operation fails on any individual data source within a data container, it will be automatically retried until it succeeds, or until the retry limit is reached.

Automatic retry applies to any Delphix Self-Service operation that changes the data in the data container, such as Refresh, Restore, Reset, or Create Branch. This setting can be especially useful in scenarios where there are a large number of sources in a data container, and some sources fail to update the first time. If the reason for the failures was intermittent, an automatic retry may allow the sources that failed to succeed, and the operation can still complete successfully. The default number of retry attempts is **1**.

To change the number of automatic retries:

1. Click the user icon in the upper right-hand corner of the screen.
2. From the drop-down menu, select **Settings**.
3. In the field **Automatically retry data sources...**, enter a new maximum; alternatively, use the arrows to increase or decrease the number.
4. Click **Save**.

## Understanding data templates

### Data templates: an overview

A data template represents a collection of data sources that you can provision to a user. A data source can be a dSource, VDB, or vFiles. These sources can be used in multiple data templates. Once you have created a data template, the set of data sources associated with it is fixed; you cannot add data sources to an existing template, nor can you remove data sources from it. In addition to data sources, you can define the set of metadata that is relevant for a given template – for example, notes, descriptions, names for sources that are relevant to an end-user, and other configuration details. Once you have created the template, it provides a stencil for provisioning data containers. This, in turn, enables users to have self-service access to a space-efficient copy of the data sources defined in the data template.

### Data template activities

Data templates are managed by a Delphix admin. The admin can provision data containers from the data template and assign a data container to an end-user. The admin can also create bookmarks on the data template timeline in order to mark meaningful points in time.

When creating a data template, it is important to consider the set of users who will own data containers provisioned from it. In Delphix Self-Service, templates effectively define the boundaries of the data that users can share directly with each other. Only owners of data containers created from the same data template are able to share data using bookmarks.

### Creating a Data template and adding data sources

A data template consists of an arbitrary set of dSources, virtual databases (VDBs), and vFiles. These are created and managed in the **Delphix Management** interface and can be used in Delphix Self-Service as data sources. You can use any data type supported by the Delphix Engine as a data source. For more information, refer to the Linking/Provisioning documentation for the standard Delphix Engine. The following is an example of the many kinds of data sources you can use to create a data template.

When adding data sources to the data template, it is important to consider whether there are any dependencies between them. For example, do data operations need to begin with a VDB (database) source before the same operation occurs on vFiles (application binary)? Or can data operations be performed in parallel with each of the data sources? The data source dependencies are by default synced together in parallel during any data operation,

including starting the data container and its sources. When working with specific ordering constraints, such as with Oracle EBS, you can set up and configure the ordering sequence for each data source.

Procedure for creating a data template

To create a data template:

1. From the drop-down menu in the upper right-hand corner of the Delphix Management application, select **Self-Service**.
2. On the **Overview** page, click **Add Template**.

This will send you to the **Create Data Template** page.

3. Enter a **Name** for the data template.
4. Optionally, enter a **description** for the data template.

5. Click **Add Data Source** to add data sources to the template. Each data source name will include the name of the datasets group with which it is associated.

*Create Data Template window with data source drop-down menu*

To select a replica data source, first, select the name of the replica it belongs to. Then pick the replica masked VDB from the drop-down menu.

6. To set a startup order, select the Set startup order of data source checkbox, then from the drop-down select the order.
7. Select **Create**.

#### Default vs. Setting the Ordering of Data Sources to a Data Template

You have the option of setting the ordering of data sources to a data template. This option executes Delphix Self-Service operations sequentially on each data source (rather than in parallel), to ensure consistency among sources that need to be started/shut down in a particular order. You cannot change this setting after the data template has been created. **If you want the default behavior of running operations in parallel, do NOT select the box labeled "Set startup order of data sources".**

When your template has ordering constraints, as with Oracle EBS, you must set the startup order for each data source. Select the **Set startup order of data sources** box. The Delphix Engine will select the data source with order 1 as the first source started and the last one to be stopped. The data source with order 2 will be selected as the second source started, and this sequence will continue until the last data source is selected and ordered. Note that it is not possible to have operations performed in parallel on a subset of data sources and sequentially on a different subset of data sources.

Configure the synchronization and consistent ordering of data sources

1. Select the **Set startup order of data sources** box.
2. Use the drop-down menu to select the **source** you want to include. The drop-down menu will display all dSources in the system and all VDBs and vFiles that are not already assigned to a Delphix Self-Service data container.
3. Enter a specific **name** for the data source.
4. Optionally, enter a **description** in the **Notes** section. Delphix Self-Service users see a copy of these notes in the data containers they own.
5. Click **Add Data Source** to continue to add and configure more data sources to the data template. You can remove data sources using the **Delete** icon.
6. By default, the **Order** of the sources will correspond to the order they are added. You can also edit the **Order** using the dropdown for each source.

7. Click **Create** to finish creating the data template.

 For Oracle EBS, the vFiles dbTechStack will have order 1, the Oracle database order 2, and the vFiles appsTier order 3. For more information about EBS, see the EBS documentation. Once you have created a template, you cannot change the set of data sources in it. Any VDBs or dSources being used as data sources in Delphix Self-Service will appear with a special badge in the Management application.

## Viewing data templates

As the Delphix Admin user, you can view what sources have been included in a data template. You can distinguish the masked sources from the unmasked sources by referring to the corresponding data icons, as seen below.

Example of a template containing both masked and unmasked VDBs

### Managing data templates

After you have created the data template, it will be visible from the **Overview** page under the **Data Templates** tab, which is the default tab.

Data Template Details in the Overview page

### Notes

- Each line corresponds to a data template and contains high-level information about that data template. For example, the number of child data containers is visible in the **Containers** column.

- You can search, sort, and filter the list of data templates, making it easy to manage a large number of data templates in Delphix Self-Service.

Editing a data template's name

1. Click the **Edit** icon next to the data template name.
2. Enter the new **name**.
3. Click the **checkmark** icon to confirm changes.

Deleting a data template

1. Select the **data template** you want to delete.
2. Click the **Delete** button in the upper right-hand corner.

**Data Containers**

If there are any data containers provisioned from the data template, you must remove them before you can delete the data template. See instructions in [Data Container Activities](#).

## Understanding how to manage data template details

### The data template details page

In the **Overview** page, under the **Templates**, click the data template's **name**. This will direct you to the templates details page. You can use this page to view and configure details of an individual data template. It consists of a number of tiles, described below.

#### Summary

Use this tile to get an overview of the data template and its child data containers.

#### Summary Details for Templates

#### Notes

- The graphs labeled **Operation Counts By Week** and **Container Data Age Distribution** give a sense of the amount of activity in the data template over time
- **Top Checkouts** shows at a glance which bookmarks have been used most frequently as part of a **Restore** or **Branch** operation
- **Top Users by Data Operations** shows at a glance which users are the most active

#### Containers

Use this tile to create, view, and delete child data containers from this data template.

#### Container Details

#### Sources

In this tile, you can view the data sources that this data template uses. Each data source has a user-visible name, a description, and a set of properties that consist of arbitrary key/value pairs. This information will be included in the data containers provisioned from this template.

### *Sources Details*

#### Properties

Use this tile to edit the data template's properties. Properties are arbitrary key/value pairs associated with the data template. These values will be propagated to all data containers provisioned from this template. This provides a way for you to annotate data templates and data containers with whatever information is relevant to their use case.

### *Properties Details*

#### Bookmarks

Use this tile to create and manage bookmarks on the data template. A bookmark represents a given point in time that is protected against retention. Bookmarks created on a data template are visible to all of the data containers provisioned from it. For more details, refer to the Bookmarks section in the [Delphix Self-Service Data User Guide](#).

### *Bookmarks Details*

#### Capacity

Use this tile to get information about the storage associated with the data template and its child containers.

## Understanding data containers

### Delphix self-service data container overview

Data containers are provisioned from data templates by administrators and assigned to a user. A data container represents a socket that is capable of making any data within the data template accessible. The user controls what data they want to access. Delphix Self-Service users have effectively been provisioned a set of "physical" resources, such as a database on a host that consumes some set of resources. A data container is comprised of a virtual database (VDB) or vFiles provisioned from each source in the data template from which it is created. The data container manages these VDBs, and the data operations performed on a data container will only impact these VDBs. Data containers represent the separation between IT infrastructure and end-users. IT determines the set of VDBs or vFiles to allocate to a data container, and users determine the data that they want accessible in the containers allocated to them.

Data containers can be used to access any data within a single data template, but not across templates. Users have the ability to populate the data within their data container from any point in time on the data template, the data container's history, or shared bookmarks from other data containers. Although operations are all accomplished by performing Timeflow operations on the underlying VDBs, the data containers hide the VDBs and their underlying properties from users. None of the data container operations require provisioning additional VDBs; everything is accomplished using the resources assigned when the data container is created.

Operation	Description
<b>Refresh</b>	This is the same basic concept as <b>Refresh</b> in VDBs. In Delphix Self-Service, <b>Refresh</b> will update the data on the active branch of a user's data container. The user will then have the latest data in the sources of the data template from which the container was provisioned.
<b>Restore</b>	<p><b>Restore</b> allows a Delphix Self-Service user to update the data on the active branch of their data container to one of the following:</p> <ul style="list-style-type: none"> <li>• any point in time on the data container</li> <li>• the data template from which the container was provisioned</li> <li>• a bookmark</li> </ul> <p>This operation effectively means, "Take me to the data at this time."</p>
<b>Reset</b>	<b>Reset</b> is a simplified version of <b>Restore</b> built to support the notion of "undo." It allows a user to reset the state of their application container to the latest operation. This can be useful for testing workflows where, after each test, users want to reset the state of their environment.
<b>Branch</b>	A branch represents a logical timeline, effectively a task on which a user is working. Only one branch can be active at a time, but a user can use multiple branches to track logically separate tasks. Delphix Self-Service branches do not require the allocation of a new VDB; instead, they are comprised of a collection of TimeFlows within a VDB.
<b>Activate</b>	This allows the user to select which branch they want to be active. Only a single branch within a data container can be active at a time.

Operation	Description
<b>Bookmark</b>	This creates a semantic name for a point in time and prevents this data from being removed by the retention policy. Bookmarks can be annotated with tags to make them easier to search for. In addition to tags, bookmarks allow a user to enter a description of what the bookmark represents.
<b>Share</b>	Bookmarks can be shared, which allows them to be seen by users who own data containers that have been provisioned from the same data template. This allows users to share data, providing a way for other users to either restore their existing timeline or create a new branch from these shared points.

Once a data operation has been selected its progress can be viewed from the Action sidebar in the Management application. From the Action sidebar, users cannot cancel the enable, disable or activate branch operations.

#### Automatic retry for data operations

To make operations on data containers more robust, Delphix Self-Service supports automatically retrying failed sources during data operations. You can specify a maximum number of retry attempts so that if an operation fails on any individual data source within a data container, it will be automatically retried until it succeeds, or until the retry limit is reached.

Automatic retry applies to any Delphix Self-Service operation that changes the data in the data container, such as Refresh, Restore, Reset, or Create Branch. This setting can be especially useful in scenarios where there are a large number of sources in a data container, and some sources fail to update the first time. If the reason for the failures was intermittent, an automatic retry may allow the sources that failed to succeed, and the operation can still complete successfully. The default number of retry attempts is **1**.

To change the number of automatic retries:

1. Click the user icon in the upper right-hand corner of the screen.
2. From the drop-down menu, select **Settings**.
3. In the field **Automatically retry data sources...**, enter a new maximum; alternatively, use the arrows to increase or decrease the number.
4. Click **Save**.

Settings in the user drop-down menu

## Delphix self-service data container recovery

### Data containers consistency

Delphix Self-Service allows you to group multiple datasets in the same data container. This makes it easy for you to access entire applications such as PeopleSoft, including binaries and code. If a data container represents an application, then there are likely to be dependencies between the application's datasets. For example, the vFiles data source containing the code will depend on a specific version of the database's schema. Therefore, it is important that all dataset sources are drawn from the same point in time. If they are, the data container is in a "consistent" state; if they are out of sync, or "inconsistent," errors will occur. For example, if the vFiles data source containing the code has been updated more recently than the database's schema, the dependency cannot work.

Delphix Self-Service currently has no way to determine whether the application is consistent. However, it attempts to minimize the chance that dataset sources are out of sync whenever it performs a data operation such as refresh, restore, or reset. When performing a data operation, Delphix Self-Service attempts to snapshot all dataset sources from a point in time as close as possible to the desired time. If at least one of the data sources fails to go to the desired point, then Delphix Self-Service considers the data container to be in an inconsistent state. The application as a whole may still be working, but Delphix Self-Service assumes that the failed dataset's data is not the correct version. To return to a consistent state, you must perform a recovery operation on the data container.

### Data container recovery

Prior to performing any data operation, Delphix Self-Service takes snapshots of all datasets. Recovery is the process of rolling back a data container to a snapshot, thereby restoring it to a consistent state. When a failure occurs, you will see the following screen:

You can either perform recovery or use a different data container. Whether the recovery will fail or succeed depends on exactly why the data operation failed in the first place. If the problem was intermittent, such as a temporary network problem causing SSH failure, then performing recovery should work. If the problem is persistent – for example, the target host is out of space – then intervention is required; recovery will not succeed until you address the underlying root cause of the failure.

Admins can see the underlying failure in the **Actions** sidebar or the **Job History** dashboard. The **Actions** sidebar is the preferred place to view the failure; it has a hierarchical display that makes diagnosing the failure more straightforward.

### Preserving independent containers in delphix self-service during replication

Replication is used for data backup and recovery as well as for managing and sharing data across remote data centers. Delphix Self-Service users can preserve their data after replication jobs. In the past, if replication occurred on templates in containers, users would lose the data in their containers. Now admin users can preserve containers to be used independently of replication jobs.

Independent containers behave in the same way as other containers, with two exceptions:

- You cannot refresh them.
- The bookmarks created on them cannot be shared, because they do not have a template reference.

The functional overview of independent containers seen below represents the flow of steps between the source engine and the target engine. A description of what is occurring between each of the steps appears below the diagram.

Functional Overview of Independent Containers

In Delphix Self-Service, you can create a template on the source engine and then replicate the template to the target engine.

the target engine, an admin can use the replicated template to create new containers and assign them to users. You cannot change the replicated template’s name or the names of the containers with which it was replicated over.

Due to an update, the replicated template is deleted from the source engine

The deleted replicated template will be removed from the target engine. Any new container created in step 2 loses the reference to the deleted template and becomes an independent container.

## Creating independent containers

### Prerequisites

- The replication source and the replication target must be running identical versions of the Delphix Engine – for example, Delphix Engine version 5.1.
- The target Delphix Engine must be reachable from the source engine.
- The target Delphix Engine must have sufficient free storage to receive the replicated data.
- The user must have administrative privileges on the source and the target engines.

For more information, see [Configuring Replication](#) and [Understanding Data Templates](#).

### Limitations of this functionality

You can find independent containers in Delphix Self-Service on the target engine under the **Independent Containers** tab. They have the following characteristics:

- They cannot be refreshed, because they are no longer bound to a template.

- You can create bookmarks on them, but you cannot share those bookmarks because there is no common template.
- You can use them for branching, restoring, resetting, starting, and stopping.

Procedure

To create an independent container, complete the following steps:

1. On the source engine, create a template with a container.
2. From the user drop-down menu, select **Management**.
3. From the **System** menu, select **Replication**.
4. Next to **Replicated Profiles**, select the **plus** icon to **Create New Profile**.
5. Under **Objects Being Replicated**, select your Self-Service **template** and its associated **container**.
6. Enter your profile information.
7. Click **Create Profile**.

When replicating templates, you can select all, some, or none of their associated containers in the replication profile. This is done by selecting the checkbox next to the container's name in the **Create New Profile** window. When replicating a container, you must also replicate its associated template. Replicated objects cannot be modified on the target engine unless they are failed over, so you cannot modify the names of replicated data containers and templates.

8. Once the profile has been created, click **Replicate Now**.
9. On the target engine, click the user menu.
10. Select **Self-Service**.
11. The replicated template will appear in Self-Service on the target engine. The replica name is displayed next to the template name. You can edit regular templates by clicking the pencil icon next to the template name.

12. Select the replicated template, then select **Containers**.
13. In the **Containers** window, click **Add Container**. In order to complete this action, you will need to ensure that there is data available from each data source in the template. This means that VDBs must have been provisioned from each replica dSource or VDB in the template. After the container is created, your replicated

template should have the new container you just created and the original container created in step 1.

14. On the source engine in Self-Service, delete your template.
15. From the user menu, select **Management**.
16. From the **System** menu, select **Replication**.
17. Replicate your profile to create a new independent container.
18. On your target engine, select **Self-Service**.
19. The new container is created. To find it:
  - a. Login to the target engine.
  - b. Click the user menu.
  - c. Select **Self-Service**.
  - d. In the Overview page, select the **Independent Containers** tab.

## Delphix self-service data container activities

### Configuring data containers in Delphix self-service

A data container is comprised of a set of virtual databases (VDBs), where each VDB is a direct child of the dSource, VDB, or vFiles in the data template's data sources. Delphix Self-Service does not automatically provision VDBs when creating a data container; a Delphix admin must create the required VDBs using the **Management** application.

**i** Once a VDB or vFile is part of a Self-Service container, you cannot use the Management Service to rewind, refresh, or delete it. You can still use the Management Service to disable or enable it, take a snapshot of it, or provision a new VDB or vFile from it.

1. Select the **Overview** page.
2. Select a **template** from which you want to create the data container. This will take you to the **Data Template** page.

#### Add a data container

1. Click **Add Container** in the upper right-hand corner of the screen.  
 *Details Panel and Dashboard* This will take you the **Create Data Container** page.

*Data Container Dialog*

- Optional: Enter information about the data container, such as the **Name** and **Description**.
- Once the data container has been created Select the **Owners** for the data container from the search box. It is acceptable to have multiple owners for each data container. Any Delphix administrator is able to manage all containers, so the owners should be end-users. For details, see [Understanding Delphix Self-Service User Management](#).

- When a data container is created, you now have the option to:

- a. **Refresh data sources to most recent template state** – This option will refresh VDBs before adding them to the container. This is done to enforce that when multiple sources are used in a container, the sources are consistent.
  - b. **Add data sources to container as-is** – This option will not refresh the data sources.
5. Select the **VDBs** to use for this container's data sources. The available VDBs have the following constraints:
  - They have been provisioned from the dSources/VDBs belonging to the parent data template
  - They are not already part of another data template or containerIf there are no VDBs that meet these constraints, you may see a message informing you that you do not have any compatible VDBs.  
  
*VDB Warning Alert*
6. Click **Create**.

## Selecting Masked Data Sources for Data Containers

### Prerequisites

- [Using Masked Data Sources with Delphix Self-Service](#)
- [Selecting Masked Data Sources in Data Templates](#)

### Procedure

Once you have selected a child masked VDB for the data container, you can see the parent-child relationship as a masked source under data sources.

*Masked*

*Data Sources Parent/Child Relationship*

As an admin user, you can select both masked and unmasked data sources in both Delphix Self-Service templates and data containers.

Delphix Self-Service users will not know whether the data in their containers and branches is masked or unmasked. All Delphix Self-Service functionality remains the same regardless of whether a data source is masked or unmasked.

The figure above is an example of a data container with masked data.

## Delete a Data Container

All data sources (VDBs and vFiles) in a Data Container are not deleted as part of the Data Container deletion process.

When performing the **Delete Container** operation, you can check the **Delete associated VDBs and vFiles** box in the dialog window to delete the data sources associated with the container.

## Data management operations

### Start a data container

Starting a Data Container does the following:

- Starts the data sources, This means that each data source listed in the **Source Details** section of the **Data Container** page will start using CPU and network resources on the host system it is running.
- Puts a copy of the data from the active branch into those data sources.

On the **Self-Service Toolbar**, click **Start**.

### Stop a data container

Stopping a data container does the following:

- If not already done, copies the current data in the data sources into the active branch of the data container
- Shuts down the data sources. This means each data source listed in the **Source Details** section of the **Data Container** page will stop using CPU and network resources on the host system.

On the **Self-Service Toolbar**, click **Stop**.

Other operations on the data container, such as Stop, Reset, and Refresh, must be performed from the **Data Management** page:

*Data Management Interface Shortcut in Delphix Self-Service Data Template*

### Locking a Container

On the Self-Service Toolbar, click **Lock**.

Locking a data container does the following:

- You become the only user who can perform operations on it.
- For all other users, the container appears disabled.

Unlocking a container

Unlocking a data container does the following allows other Self-Service users to perform operations on that container.

This operation is only enabled if a container is currently locked. Only the user who locked a container or a Delphix Self-Service administrator can unlock it.

- = In Delphix Engine version 8.0.0.0 (or later), if a Self-service data container contains an Oracle virtual PDB (vPDB) and the PDB's virtual container database (vCDB) contains more than one vPDB, the start of the container will fail with error 'failed to enable data container "<data container name>"' if the vCDB is not enabled or it is not running. Start the vCDB first (using Delphix Management UI) and then start the data container again.

## Using masked data sources with Delphix self-service

### SDD Overview

You can now replicate masked data in a VDB directly to a target Delphix Engine without transmitting the unmasked data in its parent source. This is called [selective data distribution \(SDD\)](#). Although you can run selective data distribution ad hoc, it is typically run according to a predefined schedule. In the current release, there are some best practices and limitations you should know about before using data from SDD in Delphix Self-Service. This section covers the workflow for using SDD replicated data in templates and containers. It is aimed at administrators who are familiar with the process of creating a masked VDB, SDD replication and setting up objects.

### Configuring Delphix Self-Service with Masked Data Sources

The diagram below illustrates the steps for using masked data sources in Delphix Self-Service.

Step 1: Provision a masked VDB on the source.

Step 2: Use SDD to replicate masked data to the target.

Use SDD to replicate your masked VDB to the target. The target VDB will be called the “replica masked VDB.”

**i** **Replica Masked VDBs**  
 To keep the replica masked VDB up to date, configure a refresh policy for how often it should refresh. The refresh policy should be related to the schedule for SDD updates from the source. Refreshing more frequently will result in the VDB being unavailable to Delphix Self-Service more often than needed.

Step 3: Create a data template on the target.

To create a data template:

1. From the drop-down menu in the upper right-hand corner of the Delphix Management application, select **Self-Service**.

2. On the **Overview** page, click **Add Template**.  *Add Data Template* This will send you to the **Create Data Template** page.
3. Enter a **Name** for the data template.
4. Optionally, enter a **description** for the data template.
5. Click **Add Data Source** to add data sources to the template. Each data source name will include the name of the datasets group with which it is associated.

*Create Data Template window with data source drop-down menu*

To select a replica data source, first, select the name of the replica it belongs to. Then pick the replica masked VDB from the drop-down menu.

6. To set a startup order, select the Set startup order of data source checkbox, then from the drop-down select the order.
7. Select **Create**.

Step 4: Provision child VDBs from the replica masked VDB.

1. Login to the **Delphix Management** application for the target host.
2. Click **Manage**.
3. Select **Datasets**.
4. Select the **replica** that contains the dSource or VDB to be provisioned.
5. The provisioning process is now identical to the process for provisioning standard objects.

Step 5: Add data containers and select the child VDBs as data sources.

Follow the instructions to [add a data container](#).

Select a masked child VDB as a source for the container. As an admin user, you can select both masked and unmasked data sources in templates and data containers.

Once you select a child masked VDB for the data container, you can see the parent-child relationship as a masked source under data sources.

**Data Sources**

Refresh data sources to most recent template state (ensures data consistency)  
 Add data sources to container as-is (possible that data between sources may be inconsistent)

Data Source Name	VDB	VDB or vFiles
Masked	dbdhcp2-dbdh_FWO-1489717771234	Vdbd_065 (Untitled)

**Connection Info**

Host: kgbbdhcp-tgt.dc2  
 DB Name: Vdbd\_065  
 DB Version: Oracle 11.1.0.7.0  
 Oracle Home: /u02/app/ora11107/product/11.1.0/db\_1  
 JDBC: jdbc:oracle:thin:@10.43.76.8:1521/Vdbd\_065

**Description**

**Order**  
Parallel

---

Data Source Name	VDB	VDB or vFiles
Unmasked	dbdhcp1-dbdh_IEG-1489715998270	Vdbdhcp1dbdh_IEG1489715998_38E (Untitled)

**Connection Info**

Host: kgbbdhcp-tgt.dc2  
 DB Name: Vdbdhcp1dbdh\_IEG1489715998\_38E  
 DB Version: Oracle 10.2.0.5.0  
 Oracle Home: /u01/app/ora10205/product/10.2.0/db\_1  
 JDBC: jdbc:oracle:thin:@10.43.76.8:1521/Vdbdhcp1dbdh\_IEG1489715998\_38E

**Description**

*Masked Data Sources Parent/Child Relationship*

**Refreshing Masked VDBs in Delphix Self-Service Data Templates**

Make sure that in step 4 above, you select the replica masked VDB as the source for the data template.

In order for new data to be available in the template on the target, you must do the following:

1. Refresh the masked VDB on the source. This will re-run the masking job.
2. After the refresh completes, execute the SDD spec for the masked VDB.

Wait to refresh If you do not wait until the refresh is complete, unmasked data may be sent to the targ

#### SDD update

Although you can employ a policy to drive refreshes of the masked VDB, you cannot use that policy to drive the SDD update as well. You may need a combination of policies and scripts to automate the workflow.

## Limitations

### SDD Replication Profile

You cannot add data templates to an SDD replication profile. As a result, you must create the data template on the target. This is step 3 above.

## Understanding Delphix self-service user management

### User management activities

This document describes the process of creating a user and assigning that user to a data container. It also provides an overview of the **User Details** page.

#### Creating a User

Follow the same process when creating a new user or modifying an existing Delphix user. Delphix Self-Service users do not have access to the existing admin user interface, and they can only access the **Data Container** page for containers they own.

1. From the **Management** application, select **Manage**.
2. Select **Users**.
3. Click **+** to add a new user or to make an existing Delphix Engine user a Delphix Self-Service user, select the user from the list.
4. Enter the appropriate information.

5. From the **User Type** drop-down menu, select **Self-Service Only**.
6. Press **Submit**.

The user is now a Delphix Self-Service user! They can now login to the Delphix Self-Service user interface, and you can make them the owner of a data container.

#### Notes

- Users will only be able to access the **Data Management** page. They will not be able to access the other portions of the Delphix Self-Service interface, nor the **Management** application.
- A Delphix admin user cannot be made a Self-Service Only user. However, admins can still use Delphix Self-Service and own a data container. Admins are also able to manage all data containers.
- A user who owns one or more data containers cannot be deleted.
  - For the list of data containers that a given user owns, see **User Details**.
- You cannot revoke a user's Self-Service Only role if they own any data containers.
  - For the list of data containers that a given user owns, see **User Details**.

### Assigning a user to a data container

This section describes how to assign a user (created in the previous section) to a data container. Making a user the owner of a data container allows them to perform operations such as **Refresh** on that data container. Users cannot see or manipulate data containers that they do not own. You can either assign a user when creating a new data container or modify the owner of an existing data container.

#### Case 1: Assigning a user to a new data container

1. Navigate to the **Overview** page.

2. Select a **template** from which you want to create the data container. This will take you to the **Data Template** page.
3. In the upper right-hand corner of the screen, click **Add Container**.
4. Optional: Enter information about the data container, such as the **Name** and **Description**.
5. Select the **Owners** for the data container from the search box. It is acceptable to have multiple owners for each data container.
6. Select the **VDBs** to use for this container's data sources and Save.

Case 2: Changing the owner of an existing data container

1. On the **Management Overview** page, select the **data template** from which the data container was provisioned.
2. Click the **Containers** tile in the left-hand panel.
3. Select the **trash can** icon next to the username.

4. Click the **Plus** icon.

5. Select the desired **owner** from the drop-down list.

The user you selected is now the owner of the data container and can perform operations on that data container.

### User details page

This section provides an overview of **Delphix Self-Service User Details**. This page displays graphs related to the user's Delphix Self-Service activity, as well as a list of all of the data containers that the user owns.

1. On the **Management Overview** page, click the **Users** tab.

2. Select the **name** of the desired user to go to their **User Details** page.

The following sections will display important information:

Section	Information displayed
<b>Operation Counts By Week graph</b>	Shows the aggregate of all Delphix Self-Service operations performed this user has performed on all of their containers.
<b>Container Age Distribution graph</b>	Shows the average time since a data operation was performed on all of the user's containers
<b>Containers</b>	Lists all containers that the user owns

User Details

## Working with multiple container owners

Delphix Self-Service administrators can designate multiple users as owners of a single data container. These users all share access to the same data container which means actions taken by one user will impact all users on the same data container. For example, if User A activates Branch X, User B will also see Branch X as the active branch. This ability for one user's actions to impact another user on the same containers creates new concerns for users sharing the same container. As a result, more processes should be put into place in order to coordinate usage between users. Each team is different, but strategies include:

- designating a person to perform certain data operations
- saving your work with a bookmark or creating/working on a personal branch
- being aware of who is using your data container/data before performing operations
- locking a container to prevent others from performing any operations on it

### How many owners should a container ideally be shared between?

There is no technical limit built into the software, but it is best if a team of 5-10 users shares a single data container. In most cases, having fewer owners minimizes overhead and conflicting usage. One owner per container provides maximum productivity and minimal overhead, so this feature should only be used if your infrastructure or processes require that multiple users share a container. Additionally, Jet Stream Only users currently cannot see other users with whom they share the container.

### How should users handle potentially disruptive operations?

If one user performs an operation on a data container, it will affect the other owners of that container. Additionally, each user has permission to perform the same operations on the data container; currently there are no fine-granularity permissions that limit the operations a user can perform. All operations are potentially disruptive, but the level of disruption varies by operation. If any of the following operations are performed at the same time, the second operation will fail due to a conflict when processing the job.

#### Conflicting operations

- Refresh
- Restore
- Reset
- Enable/Disable
- Create Branch
- Activate Branch
- Delete Branch
- Create Bookmark
- Delete Bookmark

If User A performs a destructive operation while User B is "using" the data container, the operation will destroy User B's current state. Currently, the interface does not provide insight into whether the data container is in use by another user.

#### Destructive operations

- Refresh
- Restore
- Reset
- Enable/Disable
- Create Branch
- Activate Branch

## Deleting objects

All owners can delete any bookmarks or branches in the container, regardless of who created them.

## Coordinating users

Opportunity for disruption increases as more owners are sharing a single container. Sharing a container works best when users can communicate with each other, such as when they are part of a team, or when they are working with the container at different times.

Additionally, these disruptions can be avoided when Delphix Self-Service users lock their containers to prevent other users from performing operations on them. Users cannot see the other users with whom they share the container. However, if a user locks a container, only that user will be able to use the container; it will appear disabled to others.

## What operations could disrupt others using a container?

Potentially disruptive operations include:

- Refresh
- Switching active branches
- Deleting bookmarks
- Creating Branches
- Un-sharing bookmarks
- Restore
- Reset
- Starting/ stopping your container

## What processes should I put in place?

The more owners you assign to a single container, the more processes you should put in place to coordinate usage between users. Each team is different, but strategies include:

- designating one person to perform certain data operations
- saving your work with a bookmark or a creating and working on a personal branch
- being aware of who is using your data container before performing operations
- locking a container to prevent others from performing any operations on it

## Where can I see which user has performed what operation?

You can see which user has performed which action in the **History** tab of the **Data Operations** screen.

Be aware that operation counts in the template view are currently tabulated based on the container, not the user performing the operation.

*Data Operations history tab*

## Where can I see which containers are unlocked/locked?

Unlocked containers can be viewed by typing “unlocked” in the search filter.

You can view locked containers by typing “locked” in the search filter. To find containers locked by a specific user, type “locked by {username}” in the search filter.

## Understanding bookmarks

### Bookmarks overview

Bookmarks are a way to mark and name a particular moment of data on a timeline. You can restore the active branch's timeline to the moment of data marked with a bookmark. You can also share bookmarks with other users, which allows them to restore their own active branches to the moment of data in your container. The data represented by a bookmark is protected and will not be deleted until the bookmark is deleted. To help manage the space used by this data, users can set an optional expiration date for a bookmark. At the end of the set date, the bookmark will automatically be deleted. Once created, you can easily locate a bookmark through one of the bookmark viewers in the interface. To understand how to use bookmarks, please refer to the [Delphix Self-Service Data User Guide](#).

### Using bookmarks in data templates

An admin user can create a bookmark on a template that will then be automatically shared to all containers created from that template. Additionally, an admin user can create a bookmark on the master template timeline with the point of time you are interested in. The bookmark will always be saved from retention policies, and a new branch can be created from this bookmark.

### Default bookmark expiration

You can set a value that controls the default expiration time, in days, for Bookmarks. This setting only applies to new bookmarks that are created through the Delphix Self-Service application, not the CLI or API. Note that this only controls the default selection; users can still disable expiration or pick a different date for a specific bookmark if they wish. This setting is disabled by default.

## Understanding Delphix self-service usage management

### Usage management dashboard overview

Data templates are comprised of dSources, virtual databases (VDBs), and vFiles. These data sources are controlled by the standard policies configured in the **Management** application of the Delphix Engine. As with existing containers, space will be reclaimed by the retention policy over time. As retention cleans up historical data, users will no longer be able to use those points in time to restore or branch. In Delphix Self-Service, an admin can create a bookmark on the data template timeline, which will prevent retention from cleaning up the data that a bookmark references.

Data containers are comprised of VDBs provisioned from the sources defined in the data template. Similar to VDBs in the **Management** application, data containers' VDBs will share blocks with the source from which they are provisioned. This prevents the referenced data on the source from being cleaned up by retention. Retention for these VDBs is controlled by the standard Delphix Engine retention policies. As on templates, bookmarks in data containers will prevent storage from being reclaimed by retention. In addition, Self-Service will ensure that the latest data on each branch is never removed.

The **Usage** pages of the data templates and data containers provide information that can help you understand how storage is being used, how to reclaim space, and how much space you are able to reclaim.

**Usage Overview** is a top-level page, along with the **Data Operations** and **Overview** pages. It contains the space usage breakdowns by data templates and users.

### Template usage overview

The **Template Usage** page, seen in the image below, contains the usage breakdowns for data templates and users. The interface is interactive and allows you to visualize data by interacting with pie charts, bar graphs, and tables. The pie chart contains information about the top 10 space consumers; the table at the bottom contains information about all of the templates and/or users.

The table below the charts includes category fields. You can find corresponding descriptions by hovering over the names of the fields in the table:

The Template Usage page

Additionally, the table allows you to sort, navigate, and interact by clicking the field category of interest. For example, to sort the table, click a **column header** such as **Unvirtualized** and the table will sort by that category. To navigate to a particular data template or user, you can click either the **pie slice** or the **name** of the template/user in the table.

Table of templates/users

The field categories display the following information:

- **Total** – The sum of the space used by the data containers provisioned from this data template and by the bookmarks created on this template. This is the space that will be freed if you delete the template.
- **Containers** – The amount of space used by the data containers provisioned from this data template. This is the space that will be freed if you delete or purge all of the data containers.
- **Bookmarks** – The amount of space used by the bookmarks on this data template. This is the space that will be freed if you delete all bookmarks on the template.
- **Unvirtualized** – The amount of space that would be used by the data in this template and its child data containers without Continuous Data.

The pie chart and table graphs can help you analyze storage usage information.

### Template usage details

The **Usage** tile appears at the bottom of the Self-Service navigation sidebar, as seen in the image below. Usage summaries are available for templates, containers, and users. For example, when you click the **Usage** tile on the **Template Details** page, the usage details you interact with will be in the context of the selected data template.

The Usage tile

## User usage overview

The **User Usage Overview** page provides graphical visualizations of space used by users assigned to data containers.

The field categories display the following information:

- **Referenced** – The amount of space used by data containers that are owned by this user. This excludes the space that this user is sharing with other users.
- **Containers Owned** – The number of data containers owned by this user

## Template usage (Containers) overview

The **Template Usage Details** page, as seen below, shows the space used by data containers provisioned from the template and the bookmarks created on the template.

### Container Usage

The stacked bar graph shows information about the top 10 space users. You can re-sort the graph based on the fields in the **Sort by** the legend on the top right-hand corner of the screen as seen in the image above. For example, if you want to know which data containers are sharing the most data with others, you can un-select **Shared (others data)** and **Unique** by clicking them in the legend.

### The Sort by legend

- i** Legend Items When the legend items are not selected, their corresponding colored boxes turn gray and the data is removed from the chart. The data and name will reappear when you re-select by clicking the grayed-out category you want.

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this data container. This assumes that it also deletes underlying data sources.
- **Shared (others data)** – The amount of space that cannot be freed on the parent data template (or sibling data containers) because it is also being referenced by this data container due to Restore or Create Branch operations. The snapshots on the template or sibling container are what use up space.
- **Shared (self data)** – The amount of space that cannot be freed on this data container because it is also being referenced by sibling data containers due to Restore or Create Branch operations, via shared bookmarks
- **Unvirtualized** – The amount of space that would be used by the data in this container without Continuous Data

### Template usage (Bookmarks) overview

As shown in the image below, the **Template Usage Details** page provides the usage information about bookmarks created on a template. The primary categories of information include **Unique**, **Shared (others data)** and **Shared (self data)**.

*Template Usage (Bookmarks)*

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this bookmark
- **Shared** – The amount of space referenced by this bookmark that cannot be freed by deleting this bookmark because it is also referenced by neighboring bookmarks or branches that have been created or restored from this bookmark
- **Externally Referenced** – The amount of space referenced by this bookmark that cannot be freed by deleting this bookmark because it is also being referenced outside of Self-Service – for example, by a retention policy.

### Container usage (Branches) overview

The **Container Usage Details** page shows the usage information about the branches and bookmarks created on a container. The primary categories of information include **Unique**, **Shared (others data)**, and **Shared (self data)**.

*The Container Usage Details page*

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this branch
- **Shared (others data)** – The amount of space that cannot be freed on the parent data template or sibling branches because it is also being referenced by this branch due to Restore or Create Branch operations. The snapshots on the template or sibling container are what use up space.
- **Shared (self data)** – The amount of space that cannot be freed on this branch because it is also being referenced by sibling data containers due to Restore or Create Branch operations, via shared bookmarks.

## Welcome to delphix self-service

Delphix Self-Service grants access to the data that users need, whenever they need it. Once users have been assigned a data container, they can control the data available within it. This means they can refresh to the latest production data, roll back to a previous point in the data container's timeline, and share data with another user without requiring any involvement from Information Technology or database administrators (DBAs). Delphix Self-service data management allows developers to be more productive while using fewer resources, dramatically improving operational efficiency.

### User roles and permissions

Self-Service has two types of users:

#### Admin user

Admin users have full access to all report data and can configure Delphix Self-Service. Additionally, they can use the Delphix Engine to add/delete reports, add/delete users, change tunable settings, add/delete tags, and create and assign data templates and containers.

#### Data user

Data users have access to production data provided in a data container. The data container provides these users with a playground in which to work with data using the self-service toolbar.

### Login

1. Access Delphix Self-Service by opening a web browser using the **IP address** or **DNS qualified hostname**.
2. Login with the **User ID** and **Password** the Delphix Administrator has provided for you.

### Changing your default locale

As a user, you can change your default locale by doing the following:

1. Click the **user login** icon in the upper right-hand corner of the screen.
2. Click the **Locale** drop-down menu.
3. Select the desired locale.

## Delphix self-service data concepts

### Understanding data sources

A data source can be a database, an application, or a set of unstructured files. Delphix administrators configure the Delphix Engine to link to data sources, which pulls in the data of these sources. The Delphix Engine will periodically pull in new changes to the data, based on a specific policy. This, in turn, begins building a custom timeline for each data source. Additionally, the Delphix Engine can rapidly provision new data sources that are space-efficient copies, allowing users to work in parallel without impacting each other.

### Understanding data templates

Data templates are the backbone of data containers. They are created by the Delphix administrator and consist of the data sources that users need in order to manage their data playground and their testing and/or development environments. Data templates serve as the parent for a set of data containers that the administrator assigns to users. Additionally, data templates enforce the boundaries for how data is shared. Data can only be shared directly with other users whose containers were created from the same parent data template.

### Understanding data containers

A data container allows data users to access and manage their data in powerful ways. Their data can consist of application binaries, supporting information, and even the entire database(s) that underlie it.

A data container allows users to:

- Undo any changes to their application data in seconds or minutes
- Have immediate access to any version of their data over the course of their project
- Share their data with other people on their team, without needing to relinquish control of their own container
- Refresh their data from production data without waiting for an overworked DBA

A data container consists of one or more data sources, such as databases, application binaries, or other application data. The user controls the data made available by these data sources. Just like data sources in a template, changes that the user makes will be tracked, providing the user with their own data history.

The **Data Container Interface** lets users view the details and status of their data container and its associated data sources, as well as manipulating which data is in those sources. The **Data Container Interface** includes a section called the **Data Container Report Panel**, which displays details about each source, including the connection information needed to access it – for example, the java database connectivity (JDBC) string for a database. This connection of information is persistent and stable for the life of the data container, regardless of what data the resources are hosting.

### Data flow

The Delphix Self-Service data flow diagram below demonstrates how a Delphix Self-Service data user accesses data sources. Data sources are connected to a Delphix Engine, which is controlled by the Delphix administrator. The Delphix administrator will connect all data sources that developers and quality assurance (QA) teams need to a data template. This data template acts as a parent source to create the data containers that the administrator will assign to data users. Data sources flow from the Delphix Engine into a data template and downstream into a data container, where a data user or users will use the data sources to complete tasks. The data container acts as a self-contained testing environment and playground for the data user. Additionally, data users are able to set, bookmark, and share data points in their container with other data users of other data containers, as long as all the data containers were created from the same parent data template.

## Understanding branches

You can organize data in the data container into task-specific groupings, called "branches." For example, you can use a branch to group all the data you have used while addressing a particular bug, testing a new feature in an application, or exploring a business analytics scenario. By default, Delphix Self-Service automatically creates the first branch of source data for you when you login for the first time. You can view the default branch and any additional branches that you create over time by clicking the Branch tab. Additionally, to the right of the default branch, you will see an interconnected branch timeline unique to whichever branch is currently active. The illustration below displays both the default branch in the Branch tab of the Data Container View Panel and the default branch timeline.

*Branch Tab*

*Branch View Panel and Branch Timeline*

A branch is used to track a logical task and contains a timeline of the historical data for that task. One branch is the "active" branch, which means that it is the branch that is currently being updated with new data from the data sources. At any time, you can change which branch is active and thus change which data is in the associated data sources.

## Delphix self-service user interface

The User Interface is organized within a single web browser page. The screen serves as a data container report and management panel.

### Data container report panel

### Data Container Workspace

### Data container report panel

The Data Container Report Panel for users consists of two tile buttons. They are summarized below as **Timeline** and **Bookmarks**.

#### Timeline

The **Timeline** tile allows you to view the timeline associated with a branch. Note that this only shows the timeline for a single branch. The branch timeline is how a user interacts with data in the container to mark, stamp, and perform tasks that occur at various points in time.

#### Bookmarks

The **Bookmarks** tile allows you to view and edit details about bookmarks within this data container and bookmarks accessible from it.

### Data container workspace

The Data Container workspace is reached by selecting a template from the Management Overview page. Select a container and then select the Data Management link.

*Data Container Workspace (Top Half)*

### Data container workspace

The Data Container Workspace contains all the tools, actions, and view panels needed to begin using Self-Service features. For example, the workspace allows a user to view the history of their data on a branch, and to refresh, reset, and restore that data.

## User login and settings drop down menu

The **user login** icon in the upper right-hand corner of the screen provides a drop-down menu with options to change your password and/or log out.

## Data container view panel

The **Data Container View** Panel, found on the left-hand side of the screen, is divided into three tabular sections: time, branches, and bookmarks. These tabs allow you to find and select data that you are interested in. Based on user selections made in the view panel, the corresponding branch timeline can change.

## Switch container

Allows you to switch between containers.

## Data container self-service toolbar

The Data Container Self-Service Toolbar allows you to perform tasks and activities with data in the current container, by clicking on the following user action icons:

- **Activate** will make a branch active
- **Bookmark** will mark an interesting point of data on a branch timeline
- **Branch** will create a branch that supports one task. A branch is a group of data time segments called a "timeline."
- **Share** will share a bookmark with users of other data containers from the same template
- **Refresh** will refresh each source in the data container on a branch timeline to the latest data in the corresponding source of the data template.
- **Restore** will restore the data to a point in time from the template, the container, or a shared bookmark.
- **Reset** will reset to the last interesting moment of data time on the current data timeline
- **Stop** will stop a data container
- **Start** will start a data container
- **Lock** will lock a data container for the current user
- **Unlock** will unlock a data container.

## Branch timeline

Use this to view the timeline associated with a branch. Note that this only shows the timeline for a single branch. The branch timeline is how a user interacts with data in the container to mark, stamp, and perform tasks that occur at various points in time.

## Understanding timelines and how to preserve data in a point in time

### Understanding timelines

#### Branch timeline

A branch timeline acts as a dynamic point-in-time interface for user actions within the branch. You can interact with the source data in the active branch by using both the branch timeline and icons along the **Self-Service Toolbar** at specific points in time. Common activities include re-setting data sources to run a test, refreshing the data container with the most current source data, and bookmarking data to share or track interesting moments of time along the branch timeline. Users work with one branch at a time to perform a series of actions related to a particular testing or debugging task such as data updates or starting and stopping data. The initial branch on your data container may include data from before the data sources were made into a container. As you work within your data container, you can create more branches overtime to run or complete separate tasks. Additionally, the data container tracks each branch and the corresponding actions you perform on the branches. To view the actions completed over the life of a branch, see the container timeline in the **Time** tab of the **Data Container View Panel**.

Branch with Timeline Segments Over the Life of the Branch

#### Container Timeline

The **Time** tab displays the data container's timeline, which acts as a wall clock of time. It shows continuous real-time across all branches and timeline segments. You can scroll up and down in the container timeline to find the point in time that interests you.

#### Time Tab Timeline

Clicking a point in time in the container timeline will display the corresponding branch timeline capturing any actions performed on the branch. Additionally, should you need to select a time between tick-marks, you can use the **time input field** in the time selector on the left side of the screen.

### Container Timeline

#### Selecting a Point in Time with the Time Selector

1. In the **time selector**, type in a **date** and **time** with the following format: Month/Day/Year Hour:Minute:Second{am|pm}. For example: 1/26/2015 1:14:13pm.
2. Press **Enter**.

The time input field will show the selected time. Now that you have entered the specific time you want, you can use the toolbar to select the data operation that you want to be performed at this point in time. Data operations can include Create Bookmark, Create Branch, and Restore.

**⚠ Invalid Time Value**  
If you type in an invalid time value, or a time that is out of range, the value you typed in will revert to the previous default that existed before.

#### Selecting a Point in Time with the Time Selector Calendar

1. In the time selector, click the **calendar** icon to the left of the input field.
2. From the window that appears, click the **date** you want to use.
3. Select and **time** you want to use.
4. In the toolbar, click the button for the data operation that you want to perform at this point in time. Data operations can include Reset, Create Branch, and Create a Bookmark.

**i Picking a date**  
The flyout will not let you pick a date that is before the first point of data time in the container, or after the present moment.

### Understanding the self-service toolbar

The **Self-Service Toolbar** contains self-service action icons that represent available actions a data user can perform. You can distinguish between available and unavailable icon actions by the use of color on the toolbar. Actions available to you will be red, and actions that are unavailable will be grey. All actions are dynamic, and

availability will change based on how you use and work with data in both the branches and data container(s) that are assigned to you.

*Self-Service Toolbar*

For example, your options for actions on the **Self-Service Toolbar** can change if the branch of the branch timeline you are working with is activated. In the illustration below, the screen shows a user working in an active branch. Notice the bright red star at the end of the timeline. This indicates that the branch is active. Also, notice which actions are and are not available to the user on the **Self-Service Toolbar**.

*Self Service Toolbar with a Point in Time selected on an Active Branch Timeline*

The **Self-Service Toolbar** is dynamic and will change based on tasks a user performs in Self-Service. These workflows will influence how and when self-service actions become available on the Self-Service Toolbar.

**Branch timeline segments**

A branch timeline with segments is a visual representation of actions taken on a branch timeline over a time span. The timeline segments represents data in time that is no longer contiguous once a user clicks **Create Branch, Refresh, Reset, or Restore** on the **Self-Service Toolbar**. A vertical bar between each of the segments appears to remind a Delphix Self-Service user that the data in one timeline segment is a completely new data start. In other words, while the data within one segment is logically contiguous, the data is never contiguous across segments. For example, the following image shows a timeline with multiple segments.

*Segmented Branch Timeline*

As mentioned above, the branch timeline becomes segmented after you have performed a specific action or task, such as **Refresh**. Based on the action, two red bubbles will appear in the time segment. The top bubble indicates where the data used for this action came from – for example, the data template, a different branch, or a shared bookmark. The second red bubble appears on the timeline as the actual data stream in a point in time from the parent data. It appears because of actions such as **Refresh**, **Reset**, **Restore**, **Create Branch** and **Bookmark**. Clicking the second bubble will show you specific details of the action, such as the specifics of the action including its name, the time the action occurred, and the data sources used at a point in time. This is illustrated below.

*Parent Data Sources and Child Data Sources*

Working with multiple branches and timelines

As you work in your data container, you can switch between branches to work on resolving a bug or to test a new application feature.

For example, consider what occurs on two different branches in a container:

Branch 1:

*Branch 1 Timeline*

Branch 2:

*Branch 2 Timeline*

A user may have actually worked with these branches in the following order over time:

Branch 1: Create a branch and use <input type="checkbox"/>
<input type="checkbox"/> Branch 2: Create another branch and use
Branch 1: Activate branch, Restore the data source and use <input type="checkbox"/>
Branch 2: Activate branch and create bookmarks <input type="checkbox"/>
Branch 2: Refresh the data source from a particular point in time <input type="checkbox"/>
Branch 2: Reset a branch to the last action (e.g., refresh) on the timeline, and use <input type="checkbox"/>

In the above illustrations, an individual branch's timeline shows all actions performed on the branch while the branch was active. The active branch timeline can be interrupted and deactivated when you choose to perform actions such as switching to another branch, **Create Branch, Activate, or Stop** a data container. Additionally, you will only be able to view actions on a single branch at a time. A better way to manage multiple branches is to go to the **Time** tab in the **Data Container View Panel**. The **Time** tab allows you to access the **container timeline**, which becomes useful as you toggle back and forth between branches to complete different tasks. The **container timeline** allows you to view all the continuous data points of time, with all actions taken on all branches in a single data container.

Container Timeline

**⚠** Merging keystores requires several manual steps. Refer to [Migrating a TDE-enabled vPDB](#) for more information.

Understanding how to preserve data in a point in time

The following illustration shows that on 8/27/14, at 9:33:09am, data was reset to the parent data branch (master) at 9:28:48am, capturing data points from 9:33:06am.

Preserve Data in a Point in Time

The black arrows above point to a tick, (representing a point in time) clicked on the branch timeline. This represents the time the **Reset** action was performed on the data container. The red arrows point to when time was captured in a data source using the **Reset** action on the branch timeline. When clicked, the reset bubble provides more details with a flyout, indicating where the data comes from and the time that the data represents. Additionally, the reset bubble detail flip card provides additional information about each data source. Specifically, the blue arrows point to the time used for each data source at this point in the data container.

**⚠** This does not show the time that was used for each source that pulled the data.

The time represented on the branch timeline varies based on many factors. For example, after you select a specific point in time on the branch timeline, the Delphix Engine will map that point to the closest usable point in time for each data source. Based on the properties of the underlying data sources, these times may be different. Not all data sources track changes at the same granularity, as illustrated below.

Point In Time

While a branch timeline can follow a continuous-time flow, the data sources being selected for each time segment may not be continuous.

## Understanding bookmarks

Bookmarks are a way to mark and name a particular moment of data on a timeline that makes it easy to search and find events later. Once a point in time is selected, you can create a bookmark. You can select a specific point in time on the branch timeline, the Delphix Engine will then map that point to the closest usable point in time for each data source. Based on the properties of the underlying data sources, time may not be the same for every data source in the container. Not all data sources track changes at the same granularity. For more information, see [Working with Bookmarks in a Data Container](#).

 **Note**  
 A bookmark captures the latest point-in-time (not exceeding the bookmark timestamp) that is available while creating the bookmark. When you access the bookmark later, it does not get a closer time even if new logs are available.

Once created, you can easily locate a bookmark through one of the bookmark viewers in the interface.

### Bookmarks tab in the data container view panel

The **Bookmarks** tab is the third tab in the **Data Container View Panel** within the data container workspace of the Delphix Self-Service interface. It allows you to find a bookmark that is within your data container and view the branch where the bookmark has been placed.

*Bookmark Tab*

### Bookmarks tile in the data container report Panel

The **Bookmarks** tile in the **Data Container Report Panel** allows you to see all bookmarks within your container and all bookmarks that other users have made available to you. Here you can also edit details about bookmarks, create new branches, and restore the active branch to the bookmark's point of data time.

*Bookmark Tile*

### Bookmark sharing permissions

When you first create them, bookmarks are private to your data container, but you can share a bookmark with other data users. Bookmarks that other users have shared with you are called "available" bookmarks. Your bookmarks will only be shared with data users in data containers created from the same data template. This is because all data containers created from the same data template have a compatible set of data sources.

### Bookmark appearance

<input type="checkbox"/>	A bookmark that is private
<input type="checkbox"/>	A bookmark you have shared
<input type="checkbox"/>	A bookmark that has been shared with you

## Data container storage and retention for branches and timelines

Bookmarks mark a moment of data. Delphix Self-Service will never automatically delete the data marked by a bookmark. However, Delphix Self-Service will automatically delete a bookmark with an expiration date set after it has expired. For more information on setting or removing an expiration date, see [Data Container Activities](#). Delphix Self-Service may delete data from any time in the past on your branches, depending on the retention policies configured by your administrator. If you select a moment of data that has been deleted, the flyout will indicate that retention has removed data for this point in time.

*Data Container and Retention*

## Data container activities

### Getting started

Data containers can be shared between multiple users. In this situation, users should coordinate with their co-owners when performing data operations that could disrupt other users' workflow such as stopping or refreshing the data container.

### Activity One: how to start and stop a data container

Starting a data container does the following:

- Starts the data sources
  - This means that each data source listed in the **Source Details** section of the **Data Container** page will start using CPU and network resources on the target system it is running on
- Makes the data in the active branch available
  - Once the container has been started, the data represented by the active branch is available

Stopping a Data Container does the following:

- Shuts down the data sources
  - This means each data source listed in the **Source Details** section of the **Data Container** page will stop using CPU and network resources on the target system.

To start a data container, click **Start** on the **Self-Service Toolbar**.

To stop a data container, click **Stop** on the **Self-Service Toolbar**.

### Working with a branch, a branch timeline, and the self-service toolbar

### Activity Two: using reset from a bookmark to facilitate destructive testing

**Reset** is a data user workflow that is optimized to enable destructive testing. **Reset** automatically restores the data to the last operation conducted in the data container, which can include creating a bookmark, resetting, or restoring data. As an example, you can do a refresh and then get your data into a state required for testing. Once you are satisfied with the state of your data, you can create a bookmark, which will preserve the data at this point in time.

Afterward, you can then run destructive tests on the data. When you are done, you can click the **Reset** icon, which will automatically restore the state of the container to the last operation – in this case, the bookmark. This workflow ensures that each test has a clean copy of the data and is not impacted by the results of other tests. You only need to create a bookmark and click **Reset** on the **Self-Service Toolbar**.

#### Create a bookmark

1. Select a **Data Point** on a branch's timeline.
2. On the **Self-Service Toolbar**, click the **Bookmark** icon.
3. In the **Bookmark Window**, enter a new **name**.

*Name a Created Bookmark*

4. Optionally, fill in a **description**.
5. Optionally, set an expiration date. The bookmark will be automatically deleted at the end of this day.
6. Optionally, add one or more **tags**.

You can use these to help filter a set of bookmarks.

7. Click **Create**.

After the bookmark has been created, you will see the **bookmark** icon appear on the timeline. When you click the **Reset** button, all data will be reset to that point in time.

Reset to data from a bookmark

Click the **Reset** icon.

This action reflects the moment of data marked by the closest operation bubble (**Refresh, Restore, Reset,** or **Bookmark**) into a new timeline segment on the active branch. It also copies the moment of data into the data sources.

Update Data with Reset

Undo data

Click the **Undo Data** icon for an operation.

Undo the given operation. This is only valid for RESET, RESTORE, UNDO, and REFRESH operations.

Activity Three: using refresh to get the latest data from a data template

1. Start a new timeline segment with the most recent point of data from the data container's data template.
2. Click the **Refresh** icon.

Refresh creates a new timeline segment on the active branch. This refreshes each source in the data container to the latest data in the corresponding source of the data template.

Update Data with Refresh

#### Activity Four: using restore to return data back to a point in time

This starts a new timeline segment on the active branch with the selected point of data.

1. Select one of the following:
  - a. A **point of data** on a timeline.
  - b. A **bookmark** on a timeline.
  - c. A **bookmark** under the **Bookmarks** tile in the **Data Container Report Panel**.
2. Click the **Restore** icon.

If you restore data back to a point in time on the data template master timeline, you will be asked which data container to restore into. It will then:

- Reflect the selected point of data into a new timeline segment on the active branch
- Copy the moment of data into the data sources

If the timeline segment on a branch timeline was created by a **Restore** operation, then the segment starts with the moment of data from the branch that was selected when the **Restore** operation was done. This is illustrated below.

- i** Parent Branch  
 The parent branch for this segment can be the same branch of which this segment is a part. It is possible to restore the active branch from a point in time on the same branch.

Update Data with Restore

**i** Source Branch  
 The source branch for this segment can be the same branch of which this segment is a part. It is possible to restore the active branch from a point in time on the same branch.

### Activity Five: restoring to a point on the parent template

Data templates serve as the parent for a set of data containers, and as a data user, you have the flexibility to restore your container to any point on the template.

1. Choose the container tab and select the template by clicking on the template name located at the top of the screen.
2. Select one of the following:
  - A point of data on the timeline
  - A bookmark on the timeline
  - A bookmark under the Bookmarks tile in the Data Container Report Panel
3. Click the restore icon
4. A dialog will pop up. Use it to select the container you'd like to restore.

### force option

**forceOption** is an API/CLI-only feature. Generally, if a source database is corrupted or otherwise prevents taking VDB snapshots, the Refresh, Reset, and Restore actions cannot be completed. With **forceOption**, you can bypass taking a pre-operation screenshot and proceed with the desired action.

Because **forceOption** does not take a snapshot of the VDB before refreshing/resetting/restoring, you cannot undo the operation afterward.

From the CLI:

1. Go to the Delphix Self-Service container endpoint.

2. Select the container.
3. Attempt the execute the operation.
4. Set **forceOption** parameter to **true**.
5. Commit the change.

The operation will now perform without taking a snapshot first.

### Activity Six: create a new branch and switch between branches

Developers and QA teams can have multiple branches that can represent data from different points in time or different sources. You have many options for how you create a new branch. These include:

- A **point of data** time on a data timeline within the Delphix Self-Service data container, or
- A **bookmark** bubble on the timeline, or
- A **bookmark** in the **Bookmarks** tile in the **Data Container Report Panel**

1. Click the **Branch**  icon to create a new branch.
2. Enter a **name** for the new branch.
3. Click **OK**.
4. On the **Self-Service Toolbar**, click the **Activate** icon.

If the inactive branch is not showing in the data container workspace:

1. Find the **branch** in the **Branch** tab.  
  
*Selection of Branches in Branch Tab*
2. Click the **Activate**  icon.
3. After a moment, the branch will become active.

#### Active branch

Within a single data container, only one branch is active at any given time. The data located at the red star of the active branch's timeline is the newest copy of the data from the data container's data sources. The active branch is distinguished by a red star, which appears at the far right of the timeline, alongside its name in the **Branch Name** area, and in the **Branch** tab.

<input type="checkbox"/>	<input type="checkbox"/>
Active branch	Inactive branch

### Activity Seven: rename and/or delete a branch

Rename the Default Branch

1. Select the **Default Branch** in the **Branch** tab.
2. Click the **Pencil** icon to the right of the name.
3. Enter the **new name**.
4. Click the **Checkmark** icon.

Delete a created branch

1. Select the **branch** in the **Branch** tab.

2. Click the **Delete** icon to the right of the name.
3. Click **Delete** in the confirmation window that appears.

## Activity Eight: restoring a data container to a consistent state with the recovery operation

### Data containers consistency

Delphix Self-Service allows you to group multiple datasets in the same data container. This makes it easy for you to access entire applications such as PeopleSoft, including binaries and code. If a data container represents an application, then there are likely to be dependencies between the application's datasets. For example, the vFiles data source containing the code will depend on a specific version of the database's schema. Therefore, it is important that all dataset sources are drawn from the same point in time. If they are, the data container is in a "consistent" state; if they are out of sync, or "inconsistent," errors will occur. For example, if the vFiles data source containing the code has been updated more recently than the database's schema, the dependency cannot work.

Delphix Self-Service currently has no way to determine whether the application is consistent. However, it attempts to minimize the chance that dataset sources are out of sync whenever it performs a data operation such as refresh, restore, or reset. When performing a data operation, Delphix Self-Service attempts to snapshot all dataset sources from a point in time as close as possible to the desired time. If at least one of the data sources fails to go to the desired point, then Delphix Self-Service considers the data container to be in an inconsistent state. The application as a whole may still be working, but Delphix Self-Service assumes that the failed dataset's data is not the correct version. To return to a consistent state, you must perform a recovery operation on the data container.

### Data container recovery

Prior to performing any data operation, Delphix Self-Service takes snapshots of all datasets. Recovery is the process of rolling back a data container to a snapshot, thereby restoring it to a consistent state. When a failure occurs, you will see the following screen:

You can either perform recovery or use a different data container. Whether the recovery will fail or succeed depends on exactly why the data operation failed in the first place. If the problem was intermittent, such as a temporary network problem causing SSH failure, then performing recovery should work. If the problem is persistent – for example, the target host is out of space – then intervention is required; recovery will not succeed until you address the underlying root cause of the failure.

Admins can see the underlying failure in the **Actions** sidebar or the **Job History** dashboard. The **Actions** sidebar is the preferred place to view the failure; it has a hierarchical display that makes diagnosing the failure more straightforward.

### Activity Nine: working with container locks

Container owners have the ability to lock/unlock containers. By default, a container is unlocked, which means that all the container’s owners can perform operations on it:

You can lock a container by clicking the **Lock** button in order to prevent other users from operating on it.

The information on who locked the container is available in three places:

- In the history below the timeline
- In the tooltip on the locked container’s name in the container selector
- In the tooltip on the locked container’s name in the container label above the timeline

### Errors

If an action such as refresh fails, a dialog box will give you further information. The **Error Details** field will

The **copy** button enables you to copy and paste error details, which you can then send to your Delphix administrator for further assistance.

*Error dialog*

## Containers with multiple owners

Delphix Self-Service administrators can designate multiple users as owners of a single data container. These users all share access to the same data container which means actions taken by one user will impact all users on the same data container. For example, if User A activates Branch X, User B will also see Branch X as the active branch. This ability to for one user's actions to impact another user on the same containers creates new concerns for users sharing the same container. As a result, more processes should be put into place in order to coordinate usage between users. Each team is different, but strategies include:

- designating a person to perform certain data operations
- saving your work with a bookmark or creating / working on a personal branch
- being aware of who is using your data container / data before performing operations
- locking a container to prevent others from performing any operations on it

### How many owners should a container ideally be shared between?

There is no technical limit built into the software, but it is best if a team of 5-10 users shares a single data container. In most cases, having fewer owners minimizes overhead and conflicting usage. One owner per container provides maximum productivity and minimal overhead, so this feature should only be used if your infrastructure or processes require that multiple users share a container. Additionally, Jet Stream Only users currently cannot see other users with whom they share the container.

### How should users handle potentially disruptive operations?

If one user performs an operation on a data container, it will affect the other owners of that container. Additionally, each user has permission to perform the same operations on the data container; currently there are no fine-granularity permissions that limit the operations a user can perform. All operations are potentially disruptive, but the level of disruption varies by operation. If any of the following operations are performed at the same time, the second operation will fail due to a conflict when processing the job.

### Conflicting operations

- Refresh
- Restore
- Reset
- Enable/Disable
- Create Branch
- Activate Branch
- Delete Branch
- Create Bookmark
- Delete Bookmark

If User A performs a destructive operation while User B is "using" the data container, the operation will destroy User B's current state. Currently, the interface does not provide insight into whether the data container is in use by another user.

### Destructive operations

- Refresh
- Restore
- Reset
- Enable/Disable
- Create Branch

- Activate Branch

## Deleting objects

All owners can delete any bookmarks or branches in the container, regardless of who created them.

## Working with bookmarks in a data container

Working with bookmarks is an easy way to share data with other users of any container created from the same template. By sharing with others, you can integrate testing, development, and QA needs. For example, in the past, if you found a bug you would wait until it was fixed. But with bookmarks, you do not have to stop your work while someone tries to fix the problem. Sharing a bookmark allows users to work with data as they see fit. Bookmarks mark a moment of data. Delphix Self-Service will never automatically delete the data marked by that bookmark. However, Delphix Self-Service will automatically delete a bookmark with an expiration date set at the end of that day.

*Bookmarks Management in the Data Report View Panel*

### Activity Nine: Share a bookmark with other Delphix self-service users

Share a bookmark

1. Select a **bookmark** by clicking one of the following:
  - The bookmark's **bubble** on the **branch timeline**.
  - The **Bookmarks** tab in the data container workspace.
  - The **Bookmarks** tile in the **Data Container Report Panel**.

2. Click the **Share**  icon.

You cannot share a bookmark that you or another user have already shared.

Unshare a bookmark

1. Select a **bookmark** by clicking one of the following:
  - The bookmark's **bubble** on the **branch timeline**.
  - The **Bookmarks** tab in the data container workspace.
  - The **Bookmarks** tile in the **Data Container Report Panel**.

2. Click the **Unshare**  icon.

You cannot unshare a bookmark that is already private or a bookmark which someone else has shared.

## Delete a bookmark

1. Select a **bookmark** by clicking one of the following:
  - The bookmark's **bubble** on the **branch timeline**.
  - The **Bookmarks** tile in the **Data Container Report Panel**.
2. Click the **Delete**  icon.

## Activity Ten: editing bookmarks

## Rename a Bookmark

1. In the **Data Container Report Panel**, click the **Bookmarks** tile. A selection of bookmarks will appear based on whether you have chosen to view private, shared, and/or available bookmarks.
2. In the **detail bookmarks** window, click the **Edit** icon to the right of its name.
3. Enter the **new name** in the edit field.
4. Click the **checkmark** to the right of the field to accept and save the new name.

## Edit the description of a bookmark

1. Select a **bookmark** by clicking the **Bookmarks** tile in the **Data Container Report Panel**.
2. Click the **Edit** icon to the right of its name.

## Remove the expiration date of a bookmark

1. Select a **bookmark** by clicking the **Bookmarks** tile in the **Data Container Report Panel**.
2. To the right of the bookmark's name, click the **Edit** icon.
3. Uncheck the **Will be deleted after** checkbox.
4. Click the **checkmark** to the right of the date selector.

## Set or update the expiration date of a Bookmark

1. In the **Data Container Report Panel**, click the **Bookmarks** tile.
2. To the right of the bookmark's name, click the **Edit** icon.
3. Check the **Will be deleted after** checkbox.
4. Use the date selector to pick a new date.
5. Click the **checkmark** to the right of the date selector.

## Activity Eleven: filter and view bookmarks

## View Only Your Created Bookmarks

In the **Bookmarks** tile in the **Data Container Report Panel**, bookmarks that belong to you are shown. To see only your own bookmarks:

1. In the **Data Container Report Panel**, click the **Bookmarks** tile.
2. De-select **Available**.

## View Bookmarks You Have Shared with Others

1. In the **Data Container Report Panel**, click the **Bookmarks** tile.
2. De-select **Private**.
3. De-select **Available**.

Only your shared bookmarks will be shown.

### View Bookmarks That Others Have Shared with You

1. In the **Data Container Report Panel**, click the **Bookmarks** tile.
2. De-select **Private**.
3. De-select **Shared**.
4. Select **Available**.

These are the bookmarks that have been shared with you.

### Adding Tags To Your Bookmark

1. In the **Data Container Report Panel**, click the **Bookmarks** tile.
2. Select the **bookmark** to which you want to add tags.
3. Click **Add a Tag**.
4. Enter the **tag name**.
5. Click the **Accept** icon.

Your tags will be shown at the bottom of the **Bookmarks** tile in the **Data Container Report Panel**.

You can only add tags to bookmarks that you have created.

### Finding Bookmarks

In either the **Bookmarks** tab in the data container workspace or the **Bookmarks** tile in the **Data Container Report Panel**:

- Type into the **Filter** field.

This will only show bookmarks that have names or tags that match the text you have entered.

## Understanding Delphix self-service usage

### Usage management Dashboard overview

Data templates are comprised of dSources, virtual databases (VDBs), and vFiles. These data sources are controlled by the standard policies configured in the **Management** application of the Delphix Engine. As with existing containers, space will be reclaimed by the retention policy over time. As retention cleans up historical data, users will no longer be able to use those points in time to restore or branch. In Delphix Self-Service, an admin can create a bookmark on the data template timeline, which will prevent retention from cleaning up the data that bookmark references.

Data containers are comprised of VDBs provisioned from the sources defined in the data template. Similar to VDBs in the **Management** application, data containers' VDBs will share blocks with the source from which they are provisioned. This prevents the referenced data on the source from being cleaned up by retention. Retention for these VDBs is controlled by the standard Delphix Engine retention policies. As on templates, bookmarks in data containers will prevent storage from being reclaimed by retention. In addition, Self-Service will ensure that the latest data on each branch is never removed.

The **Usage** pages of the data templates and data containers provide information that can help you understand how storage is being used, how to reclaim space, and how much space you are able to reclaim.

**Usage Overview** is a top-level page, along with the **Data Operations** and **Overview** pages. It contains the space usage breakdowns by data templates and users.

### Container usage overview

The **Usage Details** page, shows the space used by data containers provisioned from the template and the bookmarks created on the template.

The stacked bar graph shows information about the top 10 space users. You can re-sort the graph based on the fields in the **Sort by** legend on the top right-hand corner of the screen as seen in the image above. For example, if you want to know which data containers are sharing the most data with others, you can un-select **Shared (others data)** and **Unique** by clicking them in the legend.

**i** When the legend items are not selected, their corresponding colored boxes turn gray and the data is removed from the chart. The data and name will reappear when you re-select by click on the preferred grayed-out category.

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this data container. This assumes that also delete underlying data sources.

- **Shared (others data)** – The amount of space that cannot be freed on the parent data template (or sibling data containers) because it is also being referenced by this data container due to Restore or Create Branch operations. The snapshots on the template or sibling container are what use up space.
- **Shared (self data)** – The amount of space that cannot be freed on this data container because it is also being referenced by sibling data containers due to Restore or Create Branch operations, via shared bookmarks
- **Unvirtualized** – The amount of space that would be used by the data in this container without Delphix virtualization

### Bookmarks usage overview

As shown in the image above, the **Container Usage** page provides the usage information about bookmarks created on a template. The primary categories of information include **Unique**, **Shared (others data)**, and **Shared (self data)**.

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this bookmark

- **Shared** – The amount of space referenced by this bookmark that cannot be freed by deleting this bookmark because it is also referenced by neighboring bookmarks or branches that have been created or restored from this bookmark
- **Externally Referenced** – The amount of space referenced by this bookmark cannot be freed by deleting it because it is also being referenced outside of Self-Service – for example, by a retention policy.

## Branches usage overview

As detailed in the image above, the **Container Usage Details** page shows the usage information about the branches and bookmarks created on a container. The primary categories of information include **Unique**, **Shared (others data)**, and **Shared (self data)**.

The field categories display the following information:

- **Unique** – The amount of space that will be freed if you delete this branch
- **Shared (others data)** – The amount of space that cannot be freed on the parent data template or sibling branches because it is also being referenced by this branch due to Restore or Create Branch operations. The snapshots on the template or sibling container are what use up the space.
- **Shared (self data)** – The amount of space that cannot be freed on this branch because it is also being referenced by sibling data containers due to Restore or Create Branch operations, via shared bookmarks.

# Developer's guide

## Developer's guide

[Command line interface guide](#)

[Web services API guide](#)

## Command line interface guide

This section contains the following topics:

- [Command line interface overview](#)
- [Delphix objects](#)
- [Command reference](#)
- [CLI cookbook: common workflows, tasks, and examples](#)

## Command line interface overview

This topic provides an overview of the Delphix Engine command-line interface and links to additional topics.

The Delphix Engine provides a native command-line interface (CLI) accessible over SSH. This CLI provides an interactive layer on top of the public web service APIs, and is intended for users that wish to automate interactions with the Delphix Engine, or simply prefer a text-based interface. All of the functionality available in the CLI is also available through the public stable web service APIs should more full-featured automation be required. For more information on automation using the web service APIs, see the [Web service API guide](#).

The CLI has an internal help system and supports tab-completion to help guide users. Running the `help` command will display a list of valid commands and properties, if applicable. Specifying the command or property as an argument to `help` will display more specific information about that command or property. This guide serves as an overview of CLI operation and examples of some basic tasks, and is not a reference for all CLI commands or properties. As the CLI content is identical to the public web services, complete information about particular commands, properties, or other operations can be found in the API documentation delivered with each server instance, found at:

```
http://<server>/api
```

The API documentation is guaranteed to be consistent with the set of APIs exported by that particular server. All of the APIs used by the GUI will be supported by the CLI. While all the database and environment APIs are available, most of the system-oriented APIs (such as those required to do initial setup) will be made available in a later release.

- [Managing properties](#)
- [Array properties](#)
- [Untyped object properties](#)
- [CLI automation](#)

## Connecting to the CLI

This topic describes how to connect to the Delphix Engine command line interface.

If the same username exists in both the SYSTEM and DOMAIN namespaces (for example a sysadmin and a domain user), when logging in via ssh it is necessary for the user to explicitly provide the namespace SYSTEM or DOMAIN. For example, a user whose name exists in both namespaces must ssh in as either "someone@SYSTEM" or "someone@DOMAIN". If the user tries to log in as just "someone", the engine will give an error: Ambiguous username. Add a @DOMAIN or @SYSTEM suffix to the username.

The CLI is available over SSH or the terminal console on any Delphix Engine version 3.0 or later. To connect, use any SSH client appropriate for your workstation environment and connect to the Delphix Engine by IP or hostname on the standard SSH port (22). Enter a username for either a domain or system user followed by the namespace appropriate to that user (either DOMAIN or SYSTEM). For example:

```
ssh admin@DOMAIN@delphix-server.example.com
```

```
ssh sysadmin@SYSTEM@delphix-server.example.com
```

 The default domain user created on Delphix Engines is now **admin** instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling delphix\_admin.

At the prompt, enter your user password. Once connected, you will be placed at the CLI prompt:

```
delphix>
```

While both admin and sysadmin produce the same prompt once logged in, be aware that the two users have different menus and different functional areas.

### Sysadmin menu

```
delphix> ls
Children
network
service
storage
system
user
Operations
version
Operations
version
delphix>
```

## Delphix admin menu

```
delphix> ls
Children
alert
audit
authorization
connectivity
database
environment
fault
group
host
job
namespace
network
policy
replication
repository
service
session
snapshot
source
sourceconfig
system
timeflow
user
Operations
version
delphix>
```

Individual commands passed as arguments to the SSH client will be interpreted as if they had been read from the terminal. More complex scripts can be passed as input to the SSH command. When running SSH in non-interactive mode via these mechanisms, the command line prompt will be suppressed, as will terminal font decorations such as underline and bold.

The CLI is also available from the serial terminal console should the network be unavailable. Consult your VM platform documentation for information on how to connect to the terminal console. Once connected, log in using your Delphix user credentials just as you would over SSH.

If the management service is unavailable due to a software bug or other problem, the CLI can still be accessed as a system user provided that user is locally authenticated (not via LDAP) and has logged in at least once before. While in this state, only the `system` commands are available, including `restart`, which will attempt to restart the management service without rebooting the entire server. If this problem persists, please contact Delphix support.

The topic [CLI cookbook: configuring Key-Based SSH Authentication for Automation](#) shows an example of how to connect to the CLI using SSH key exchange instead of the standard password-based authentication.

## CLI contexts

This topic explains the concept of contexts within the Delphix Engine command-line interface.

The CLI is built on the concept of modal “contexts” that represent an administrative point for interacting with the web service APIs. These contexts can be divided into the following types:

Context	Description
<b>Static children</b>	These contexts exist for the purpose of navigating between points in the hierarchy, but have no properties of their own and do not correspond to any server-side object. The root context is an example of this, as are most of the top-level contexts such as <code>database</code> or <code>group</code> .
<b>Object</b>	These contexts represent an object on the server, either a specific object (such as databases) or system-wide state (such as SMTP configuration). These contexts have properties that can be retrieved via the <code>get</code> command.
<b>Operation</b>	These contexts represent a request to the server. Commands may or may not require input and may or may not change state on the server, but in all cases require an explicit commit operation to execute the command. When in a command context, the prompt includes a trailing asterisk (*) to indicate that <code>commit</code> or <code>discard</code> is required before exiting the context.

User can move between contents by typing the name of the context. To move to a previous context, the `up` or `back` commands can be used. In addition, the CLI supports UNIX-like aliases for `cd` and `ls`, allowing navigation similar to a UNIX filesystem. For more information on these commands, see the [Command Reference](#) section.

## Managing objects

This topic describes the use of objects in the Delphix Engine command-line interface and provides a list of the object management operations.

The Delphix Engine represents state through objects. These objects are typically managed through the following operations, covered in more detail in the [Command Reference](#) topics.

The topic [CLI cookbook: Changing the Default Group Name](#) illustrates the use of object management commands such as `list` and `get`.

Operation	Description
<code>list</code>	For a given object type (represented by a static context such as <code>database</code> ), list the objects on the system, optionally constrained by some set of attributes. Some objects are global to the system and do not support this operation.
<code>select</code>	Select a particular object by name to get properties or perform an operation on the object. See the “Delphix Objects” section for more information on object naming.
<code>get</code>	Display all or some of the properties of an object after selecting it.
<code>update</code>	Enter a command context to change one or more properties of an object after selecting. Not all objects support this operation, and only properties that can be edited are shown when in the update command context.
<code>create</code>	Create a new instance of the object type from the root static context. Not all objects can be created in this simplified fashion. Databases, for example, are created through the <code>link</code> and <code>provision</code> commands.
<code>delete</code>	Deletes an object that has been selected. Not all objects can be deleted.

In contexts where there are multiple objects of a given type, the `list` command can be used to display available objects, and the `select` command can select an object for subsequent operation.

When listing objects, each context has its own set of default columns to display. The `display` option can be used to control what columns are displayed to the user. This is a comma-separated list of property names as they would be retrieved by the `get` command. It is possible to specify properties that do not exist in order to accommodate lists of objects of varying types and untyped objects.

The topic [CLI cookbook: Listing Data Source Sizes](#) provide an example of using the `list` command.

## Managing properties

This topic describes the use of properties in relation to objects in the Delphix Engine command-line interface.

Object properties are represented as a hierarchy of typed name/value pairs. The `get` command by itself will display the complete hierarchy for a particular object. This hierarchy is displayed with each nested object indented by an additional level. The set of available properties depends on the command context and may change if the type of an object is changed.

### Property state

Properties are typically set to a specific value, but they can also be `unset`. Unset properties indicate there is no known value, either because it hasn't been provided yet, or it has been explicitly removed. Properties in this state are displayed via the following means:

- `(unset)` – The property is not currently set. It may never have been given a value or it may have been explicitly unset through the `unset` command.
- `(required)` – This has the same underlying semantics as `(unset)`, but indicates that the property **must** be set before the current command can be committed. Failure to do so will result in a validation error at the time the commit operation is attempted. Required properties are displayed in bold.

In addition, all objects have a default state when in command context. A property that has been modified is noted with an asterisk (\*), and can be reverted to its default state through the `revert` command.

When updating properties, only those properties are sent to the server. The exception is arrays and untyped objects, covered in [Array properties](#) and [Untyped object properties](#). These objects are always sent in their entirety, so changing any one element will send the entire object.

### Basic properties

Most properties are displayed and input as a string, though the underlying type may be more specific. The following are some of the basic types:

- **String** – An arbitrary string. This may be subject to additional validation (such as an IP address) that is enforced at the time the property is set.
- **Number** – An integer number.
- **Boolean** – Either “true” or “false”.
- **Enumeration** – A string that must be chosen from a known set of options.

### Nested properties

Some properties are in fact other objects and are represented as a nested set of properties. These properties can be manipulated in one of two ways: by specifying a dot-delimited name or changing the context via the `edit` command.

A dot (.) in a property name indicates that the portion to the left of the dot is the parent object name, and the portion to the right is a child of that object. For example, `sourcingPolicy.logsSyncDisabled` denotes the `logsSyncDisabled` property within the `sourcingPolicy` property. These dots can be arbitrarily nested. An alternative syntax of using brackets to enclose property names (`sourcingPolicy[logsSyncDisabled]`) is also supported for familiarity with other programming languages.

The `edit` command, in contrast, will change the current context such that all properties are relative to the specified object. This can be useful when changing many nested properties at once, or when the complete set of properties can be confusing to manage all at once.

The topic [CLI cookbook: Disabling LogSync for a dSource](#) provides an example of manipulating nested properties.

## Array properties

This topic describes the use of array properties in the Delphix Engine command-line interface.

Some Delphix objects represent properties as arrays. Arrays are effectively objects whose namespace is a contiguous set of integers. While they behave like objects and their properties can be referenced via the same object property notation, they differ in several key areas.

Arrays can be divided into two types: arrays of primitive types (strings, integers, etc.) and arrays of objects. Arrays of objects can be managed like other objects via nested property names and the `edit` command, but differ in the following respects:

- When an array element is `unset`, it removes the element from the array and shifts all other elements down to preserve the contiguous index space.
- New array elements can only be appended to the end of the array by specifying an index that is one more than the maximum index of the array.
- When displaying a property that is an array, if the length is greater than 3, then it is displayed only as “[...]”. The complete contents of the array can be displayed by getting or editing that particular property.

Arrays of primitive types can be managed as arrays of objects, but also support an inline notation using comma-separated notation. This allows single-element arrays to be set as standard property, and for arrays of strings to be set on a single line instead of having to edit each element.

Regardless of the element type, arrays are sent as complete objects when updated. When any array element is changed and subsequently committed, the complete array is sent to the server. When a single array element is reverted, the entire contents of the array are reverted.

The topic [CLI cookbook: Setting Multiple Addresses for a Target Host](#) provides an example of working with a property that is an array of strings.

## Untyped object properties

This topic describes the use of the `type` field in the Delphix Engine command-line interface object model, and the use of untyped objects.,

Most Delphix objects are typed, meaning they have a `type` field that controls what properties are available and their types. Object types and their associated hierarchy are described in more detail in the topic [Object Type Hierarchy](#) topic. In contrast, some properties are “untyped” objects, which means that there are no constraints on the property namespace, and all properties are plain strings. These objects are used for database configuration templates and other scenarios where the property namespace is unbounded or under the control of the user.

Untyped objects are always sent in their entirety when making updates. This means that when any one value is changed and then committed, all values are sent. In addition, when reverting a single value within an untyped object, the entire parent object is reverted to its default state.

## CLI automation

This topic describes using automation with both the Delphix Engine command-line interface (CLI) and the web service API.

All functionality is available in both because the CLI is built upon the web services API. The CLI enables you to create scripts for simple automation, and it is a useful aid in the development of more complex code that uses the web service API.

### Using the CLI for simple scripts

For simple automation, you can build routines that make CLI calls through SSH.

This snippet lists all environment names. It leverages the SSH key exchange explained in [CLI cookbook: Configuring Key-Based SSH Authentication for Automation](#) so that no password is required for the user named "automation".

```
DELPHIX_ENGINE=172.16.180.33
SSH_CMD="ssh automation@${DELPHIX_ENGINE}"

${SSH_CMD} "cd host; list display=name"
```

### Backward compatibility

Both the CLI and web services API are versioned to support backward compatibility. Future Delphix versions are guaranteed to support clients that explicitly set a version provided the major version identifier is compatible. For more information, see the [Web Service API Guide](#). The CLI will always connect with the latest version, but the `version` command can be used to both display the current version and explicitly bind to a supported version.

Users building a stable set of scripts can run `version` to get the current version. Scripts can then run the `version <id>` command to guarantee that their scripts will be supported on future versions. For more information on the different API versions and how they map to Delphix versions, see the [API Version Information](#) section.

### Parsing CLI output

**The default text output of the CLI is unstable.** Any attempt to parse the output is certain to run into difficulties in repeatable results for unknown input, as well as instability as the text output is changed in subsequent releases. Column headings, column order, and the number of columns will change in subsequent releases.

You can specify a version in your scripts to counteract this, but you will not be able to take advantage of new features and fixes.

### CLI as a development tool for complex automation

While the CLI is useful for simple automation tasks, it can be slow and overly complicated due to the many round trips needed to control the automation logic. For example, to disable all the environments for an engine, you could write a script which lists the environments and modifies each one:

```
DELPHIX_ENGINE=172.16.180.33
SSH_CMD="ssh automation@${DELPHIX_ENGINE}"
```

```
env_array=(`${SSH_CMD} "version 1.5.0; cd environment; list display=name" | grep -v
NAME` )
for i in "${env_array[@]}"
do
    ${SSH_CMD} "version 1.5.0; cd environment; select $i; disable; commit"
done
```

This script works, but it will be slow on systems with many environments since each SSH command will start a new session.

The web service APIs are superior when performing many operations as a single logical unit. The web service APIs also provide substantially more data with a single call than what is shown in the CLI output, which can greatly simplify your code and avoid multiple round trips.

However, the input and output of web service API calls are JSON data, and it can be difficult to quickly determine what the input and output will look like.

For this reason, the CLI provides two options that can greatly assist you in the development of complex automation: **JSON Output** and **Tracing**.

`(setopt format=json)` changes the CLI to the output of all results to parseable JSON (javascript object notation). This is the fastest and easiest way to quickly see what the JSON output will look like when executed via the Web Service APIs. The JSON format has wide support in a variety of programming languages; see <http://www.json.org> for more information.

`(setopt trace=true)` will display the underlying HTTP calls being made with each operation and their JSON payload. This allows you to determine the GET and POST calls, and their JSON payloads, which perform the actions that you need to power your automation.

`(setopt format=text)` changes the CLI back into its regular output mode. `(setopt trace=false)` turns off the trace display.

 Using both options will show the JSON output twice

The fastest way to develop complex automation is to experiment with the CLI and copy the underlying API calls to a custom system for better control over behavior.

```
delphix421> setopt trace=true
delphix421> cd user
delphix421 user> create
delphix421 user create *> ls
Properties
  type: User
  name: (required)
  authenticationType: (unset)
  credential: (unset)
  ..... (Output Truncated) .....
  userType: DOMAIN
  workPhoneNumber: (unset)
delphix421 user create *> set name=Jose
delphix421 user create *> set authenticationType=NATIVE
delphix421 user create *> set credential.password>Password1
delphix421 user create *> commit;
```

```
=== POST /resources/json/delphix/user ===
{
  "type": "User",
  "name": "Jose",
  "authenticationType": "NATIVE",
  "credential": {
    "type": "PasswordCredential",
    "password": "Password1"
  }
}
=== RESPONSE ===
{
  "type": "OKResult",
  "status": "OK",
  "result": "USER-35",
  "job": null,
  "action": "ACTION-107"
}
```

Using the output above, you can see that to create a user you must use the URL "http://myengine/resources/json/delphix/user". You will use a POST command and pass a JSON payload which looks like the above. You will get a JSON response like the above, and can validate that the status is "OK".

## Delphix objects

These topics describe the object model for the Delphix Engine command-line interface.

The Delphix object model is a flexible system for describing arbitrary hierarchies and relationships of objects. In order to enable the current and future functionality of the system, the relationship between objects is not always immediately obvious. The CLI is merely a veneer atop the web services layer to ensure that the full complement of functionality expressed by the API is always available, but this requires users to have some understanding of how objects are represented in the system.

This section covers the following topics:

- [Object type hierarchy](#)
- [Object names and references](#)
- [Databases and environments](#)
- [Asynchronous jobs](#)

## Object type hierarchy

This topic describes the object type hierarchy for the Delphix Engine command-line interface.

All Delphix objects have an associated type. This type determines what properties are available for a particular object, the format of those properties, and controls how the system interprets objects and commands. The type hierarchy uses polymorphic inheritance to allow for common properties and behavior to be defined at a single point while permitting dramatically different types of objects to co-exist without requiring a completely separate API for each. For example, the `SourceConfig` object is the base type for all external database configurations, but it has children that include `OracleSIConfig` and `OracleRACConfig` types that refer to a single instance and RAC databases, respectively.

When specifying input types, the system will attempt to determine types appropriate for the current operation, but there are times when the type must be explicitly set, either because the operation supports multiple possible inputs, or the object can embed an abstract type. In these cases, it may be necessary to explicitly set the `type` property. Setting the type may change the set of visible properties and the resulting validation that is performed, but it will not affect any properties that are already set.

## Object names and references

This topic describes the use of object names and references in the Delphix Engine command-line interface.

Most Delphix objects are persistent objects in that they have a well-known identity on the server and associated persistent state. The exceptions are objects used only as input to other operations, or global objects that have a persistent state but don't require any explicit identity since they always exist.

Persistent objects have both a name and a reference. The reference is the canonical identifier for the object and remains valid even if the object is renamed on the server. It is an opaque token that should never be interpreted by the client; the format may change in future releases though backward compatibility with current references will be maintained. All web service APIs operate using references. References can be used in the CLI when selecting objects, but given that they are a programmatically generated internal concept, they are difficult for most users to use.

The object name, on the other hand, is a much more convenient way to refer to objects but suffers from the fact that it is not guaranteed to be globally unique. When displaying or setting references, the CLI will convert to or from the 'canonical name' based on the type of the reference and the current set of objects on the system. The canonical name has the form:

```
<Type>:/<Parent>/<Object>@<Namespace>
```

The type, parent, and namespace are only included if the local object name conflicts with other objects on the system that would otherwise be valid for the given type specification. Not all objects have names relative to their parent; groups, environments, users, and many other objects are globally unique on the system. This "best fit" method is used both when displaying references as well as when setting properties that are references. If the given name potentially matches multiple objects when attempting to set a reference property, then an error is displayed that includes a list of possible names to clarify which object is being referred to. The conversion from reference to name on display only happens with text output format. When the output format is JSON, the raw content is displayed (including the local name) and it is up to the consumer to format names appropriately based on their semantics. The conversion from name to reference when setting properties always occurs. Consumers can use references, optionally prefixed with a backtick ( ` ) character to signify they are references in the unlikely event that someone has created an object with the same name as a valid reference.

 Providing unique names for objects without the use of forward slashes ( '/') and at signs ( '@' ) will provide the simplest CLI experience when referencing objects.

Here are some scenarios for databases and groups and their resulting behavior:

### No conflicting database name

The local name will be used when displaying references to the object, and can be used when setting references:

```
set container=example
```

### Databases with the same name in different groups

The parent group name must be used when displaying references to the object and when setting references to the object:

```
set container=group1/example
```

### Databases with the same name in different namespaces

The namespace name must be used when displaying references to the object and when setting references to the object:

```
set container=example@namespace
```

**Objects of different types but with the same name**

This conflict is exceptionally rare, as the reference context typically constrains the set of possible objects to be a single type, but there are cases (such as alerts, or policy targets) that can be applied to any object. In these cases, the type name must be included to uniquely identify the object:

```
set target=Container:/group1/example
```

In the event that one of the named components contains a slash ('/') or an at-sign ('@'), single quotes must be used to disambiguate the name from its parent or namespace.

## Databases and environments

This topic describes the relationship between database container objects and environments in the Delphix Engine object model.

The core Delphix objects revolve around the notion of environments and databases, known at the API layer as **containers**. Understanding how these objects relate to each other is crucial to operating effectively within the CLI. This section provides an overview of these objects; for more information about a particular representation such as Oracle RAC, see the [Web Service API Guide](#).

**i** In variations of a use case where a database propagates down to lower environment databases (for keeping consistent data), records created in the lower tables would likely be overwritten by the propagating database once they are synced. Delphix is keeping track of changes at the data block level on disk, which would render this result. As a solution, you could create a clone of the propagating database and then programmatically compare/merge the changes. You can also use a product like Oracle Goldengate, HVR, IBM Datastage, etc, to capture (extract) and propagate (replicate to lower) changes.

### Environment components

- An **environment** is the root representation of the external state that manages database instances. An environment could be a single host ( `UnixHostEnvironment` ) or an Oracle cluster ( `OracleClusterEnvironment` ). Environments exist to contain repositories, and each environment may have any number of repositories associated with it.
- A **repository** is an entity that contains database instances. Repositories are typically installation directories ( `OracleInstall` ) within an environment. Within each repository is any number of `SourceConfig` objects, which represent known database instances.
- The **source config** exists independent of Delphix, and could represent a possible dSource (in which case there is no associated database object), or could be managed entirely by Delphix (for VDBs). The source config contains intrinsic properties of the database instance, while the source (described below) contains information specific to Delphix and only exists when the source config is linked to a dSource or VDB.

Most environment objects are created through the act of **discovery**. By specifying a host, Delphix will attempt to automatically discover all environments, repositories, and source configs. These objects can also be added manually after the fact in cases where discovery fails.

The environment hierarchy can be represented as depicted below. The generic type is listed in the top portion of each box, with an example of the Oracle single instance objects in the lower portion of each box. Each of these objects can contain multiple child objects with it.

Database components

The core of all databases within Delphix is the container that holds all the physical data associated with the database, whether a dSource or VDB. Within each container is a **Timeflow**, which represents a single timeline of change within the database history. Currently, a container can only have one Timeflow, though this limitation may be relaxed in a future release.

Within a Timeflow are two important objects: `TimeflowSnapshot` objects and `TimeflowRange` objects. Timeflow **range** represents the provisionable ranges within the history of the Timeflow, while Timeflow **snapshot** represents a point at which a snapshot was taken and therefore is more likely to provision in a short amount of time.

The environment hierarchy can be represented as depicted below. Each container may be associated with a **source**, which is the Delphix representation of an external database when it is associated with a container, and contains information specific to managing that source. Not all source configs within an environment have a source associated with them (as is the case with linkable databases), but all sources must have a source config. Containers may have no sources associated with them if they are unlined; sources can be manually attached at a later point. Currently, each container can have at most once source associated with it, though this may change in a future release.

## Asynchronous jobs

This topic describes conditions under which command-line interface operations may spawn jobs that run in the background and using the `wait` option to wait for job completion.

Not all operations can be performed in the context of a single web service API call. For cases where there is a long-running operation that cannot be executed quickly and transactionally, a job may be dispatched to do the remaining work in the background. For more information on jobs and their semantics, see the topic [Viewing action status](#). Within the CLI, any command can potentially result in an asynchronous operation. The default behavior is to wait for any such job to complete and display its progress in the CLI.

In the event that you do not want to wait for the operation to complete, the global wait option can be set (`setopt wait=false`). If disabled, the CLI will display the reference to any job that was dispatched, but not wait for it to complete.

## Command reference

These topics describe the core built-in commands within the CLI. It is not an exhaustive list of all commands in all contexts. For an object or type-specific commands, consult the API documentation.

This section covers the following topics:

- [CLI help and display commands](#)
- [CLI context commands](#)
- [CLI object commands](#)
- [CLI miscellaneous commands](#)
- [CLI property commands](#)

## CLI help and display commands

This topic describes help and display commands for the Delphix Engine command-line interface.

Command	Description
<code>children</code>	Display all statically defined children valid for the current context. These children can be targets of the <code>cd</code> command.
<code>commands</code>	Display all build in commands valid for this context.
<code>help</code>	Display all commands and properties valid for the current context. Specifying a command or property will provide more information about that command or object. When nested properties are present, only top-level properties are displayed by default, though specifying a particular property will display the entire hierarchy.
<code>ls</code>	Display children, commands, objects, and operations valid in the current context. Only those sections that are relevant in the current context are displayed.
<code>operations</code>	Display available context-specific operations. These operations require an explicit <code>commit</code> command to execute the operation, or <code>discard</code> to abort it.

## CLI context commands

This topic describes context commands for the Delphix Engine command-line interface.

Command	Description
<code>back</code>	Return to the previous visited valid context. This history only tracks contexts that were actually visited, so running <code>database "example"</code> followed by <code>back</code> will return you to the root context, not the database (because the two were executed as part of one action and never actually visited). If a previous context was deleted or is no longer valid, this command will skip over it.
<code>cd</code>	Switch to the given child. This is identical to typing the name of the child itself, but also support UNIX-style directory structures, such as <code>/</code> and <code>..</code> . This allows for contexts to be chained such as <code>cd ../database/template</code> .
<code>history</code>	Display the history of input to the shell. The shell supports the ability to move back and forth in the history using the up and down arrows.
<code>up</code>	This is an alias for <code>cd ..</code> for the benefit of those less familiar with UNIX filesystem navigation. Unlike <code>back</code> , which only returns to the previous context only if it was visited, and may return to a child context, this command will always return to the immediate parent context.

## CLI object commands

This topic describes object commands for the Delphix Engine Command Line interface.

Command	Description
<code>list</code>	List all objects of a particular type when in the appropriate root context. Different contexts may support different options to the list command to constrain the output; run <code>help list</code> to see possibilities.
<code>select</code>	Select an object by name within a list.

## CLI miscellaneous commands

This topic describes miscellaneous commands for the Delphix Engine command-line interface.

Command	Description
<code>echo</code>	Print the input arguments.
<code>exit</code>	Exit from the current CLI session. This is equivalent to sending the EOF control character (typically Ctrl-D) or closing your client SSH application.
<code>getopt</code>	Get the current value of a global configuration option. The list of global options can be retrieved by running <code>help getopt</code> , but include options for controlling JSON output ( <code>format</code> ), tracing HTTP calls ( <code>trace</code> ), and enabling synchronous job semantics ( <code>wait</code> ).
<code>setopt</code>	Set the value of a global configuration option.
<code>version</code>	Display the current API version or bind to a particular version. See the <a href="#">CLI automation</a> section for more information.

## CLI property commands

This topic describes property commands for the DelphixEngine command-line interface.

Command	Description
<code>commit</code>	When in operation context, commit the changes and execute the operation.
<code>discard</code>	When in operation context, discard any changes and abort the operation.
<code>edit</code>	Change the current context to be relative to a particular object property when in operation context.
<code>get</code>	Get all properties (with no arguments) or a particular property of the current object.
<code>revert</code>	Revert a particular property to its default value, either the value of the underlying object during an update or the default command input value.
<code>set</code>	Set the value of one or more properties. These properties can be specified as <code>name=value</code> , or as simply the property name. When only the property name is specified the CLI will prompt for the value to use, optionally obscuring the input if the property is a password.
<code>unset</code>	Clear the current value of a property. This is not the same as reverting the property, though this can have semantically identical behavior in the case that the default value is unset.

## CLI cookbook: common workflows, tasks, and examples

This section contains the following topics:

- [Authentication and users](#)
- [CLI cookbook: system administration](#)
- [CLI cookbook: hosts and environments](#)
- [CLI cookbook: source databases and dSources](#)
- [CLI cookbook: VDBs](#)
- [CLI cookbook: replication](#)
- [CLI cookbook: Delphix self-service actions](#)
- [CLI cookbook: hooks and hook templates](#)
- [CLI cookbook: network performance](#)
- [Kerberos CLIs](#)

## Authentication and users

These topics describe command-line interface procedures for authentication and managing users.

- [CLI cookbook: configuring SAP ASE manual discovery](#)
- [CLI cookbook: changing HTTP and HTTPS web connections](#)
- [CLI cookbook: configuring key-based SSH authentication for automation](#)
- [CLI cookbook: setting up SSH key authentication for UNIX environment users](#)
- [CLI cookbook: configuring SSH host verification for UNIX environments](#)

## CLI cookbook: configuring SAP ASE manual discovery

## Overview

This topic describes how to use CLI commands to manually add ASE repositories to an SAP ASE environment. Discovery is the process by which the Delphix Engine identifies data sources and data dependencies on a remote environment. SAP ASE repository discovery is done automatically when an environment is added to the Delphix Engine or when an already added environment is refreshed. In some cases, automatic discovery does not discover all of the repositories in an SAP ASE environment. These repositories may be added using manual discovery.

- Unlike automatically discovered instances, manually discovered instances are not automatically deleted if the environment is refreshed when the instance is not running. The physical attributes such as ASE listener port, installation directory, and instance owner are not updated during an environment refresh either. If you change a physical attribute, you must manually update the repository.

To manually discover an SAP ASE repository you will need to:

- Add an SAP ASE environment
- Use CLI to manually discover a repository

## Creating an SAP ASE environment

Please refer to [Adding an SAP ASE Environment](#) for detailed steps.

## Manually discover a repository

This example uses `sc-dev3.dc1` as the example environment.

1. Log into CLI and cd to the **repository** menu:

```
$ ssh admin@sc-dev3.dc1
Password:
sc-dev3.dc1> cd repository
sc-dev3.dc1 repository>
```

2. Add (manually discover) an SAP ASE repository instance:

- **Note:** The values used in the following code block are specific to the example instance we are adding.

3.
 

```
sc-dev3.dc1 repository> create
sc-dev3.dc1 repository create *> ls
Properties
  type: ASEInstance
  credentials: (unset)
  dbUser: (unset)
  dumpHistoryFile: (unset)
  environment: (required)
  installationPath: (required)
  instanceName: (required)
  instanceOwner: (required)
```

```

isqlPath: (unset)
linkingEnabled: true
ports: (required)
provisioningEnabled: true
servicePrincipalName: (unset)
staging: false
version: (unset)
sc-dev3.dc1 repository create *> set credentials.type=PasswordCredential
sc-dev3.dc1 repository create *> set credentials.password=sybase
sc-dev3.dc1 repository create *> set dbUser=sa
sc-dev3.dc1 repository create *> set environment=rh610-ebf-ase-tgt-
dev3.dc3.delphix.com
sc-dev3.dc1 repository create *> set installationPath=/opt/sybase/15-7/sp139/
install
sc-dev3.dc1 repository create *> set instanceName=ASE157_TGT
sc-dev3.dc1 repository create *> set instanceOwner=sybase
sc-dev3.dc1 repository create *> set ports=5400
sc-dev3.dc1 repository create *> ls
Properties
  type: ASEInstance
  credentials:
    type: PasswordCredential (*)
    password: ***** (*)
  dbUser: sa (*)
  dumpHistoryFile: (unset)
  environment: rh610-ebf-ase-tgt-dev3.dc3.delphix.com (*)
  installationPath: /opt/sybase/15-7/sp139/install (*)
  instanceName: ASE157_TGT (*)
  instanceOwner: sybase (*)
  isqlPath: (unset)
  linkingEnabled: true
  ports: 5400 (*)
  provisioningEnabled: true
  servicePrincipalName: (unset)
  staging: false
  version: (unset)
sc-dev3.dc1 repository create *> commit
`ASE_INSTANCE-3
sc-dev3.dc1 repository>

```

### Updating a repository

Adding onto the above, the following example illustrates updating an SAP ASE instance's version after upgrading SAP ASE:

 Take caution when setting the version string. Make sure it matches the output as displayed by the "select @@version" query all the way out to the patch level (PL). For example, "15.7 SP138" or "16.0 SP02 PL01".

```

sc-dev3.dc1> repository
sc-dev3.dc1 repository> select ASE157_TGT
sc-dev3.dc1 repository 'ASE157_TGT'> update

```

```
sc-dev3.dc1 repository 'ASE157_TGT' update *> set version="15.7 SP139"
sc-dev3.dc1 repository 'ASE157_TGT' update *> ls
Properties
  type: ASEInstance
  credentials:
    type: PasswordCredential
    password: *****
  dbUser: sa
  dumpHistoryFile: (unset)
  installationPath: /opt/sybase/15-7/sp139/install
  instanceOwner: sybase
  isqlPath: /opt/sybase/15-7/sp139/install/OCS-15_0/bin/isql_r64
  linkingEnabled: true
  ports: 5400
  provisioningEnabled: true
  servicePrincipalName: (unset)
  staging: false
  version: 15.7 SP139
sc-dev3.dc1 repository 'ASE157_TGT' update *> commit
sc-dev3.dc1 repository 'ASE157_TGT'>
```

## CLI cookbook: changing HTTP and HTTPS web connections

By default, the Delphix Engine allows both HTTP and HTTPS web connections. The following steps provide instructions on how to change their configuration:

1. Via CLI, login to the Delphix Engine as a system administrator (sysadmin).
2. Go to "service > httpConnector".
3. Initiate an update.
4. Set "httpMode" to the desired value among:
  - a. "BOTH": accepts HTTP and HTTPS connections (this is the default)
  - b. "HTTPS\_ONLY": accepts only HTTPS connections
  - c. "HTTP\_ONLY": accepts only HTTP connections
  - d. "HTTP\_REDIRECT": accepts HTTPS connections and redirects HTTP connections to HTTPS.
  - e. "HTTP\_REDIRECT\_WITH\_HSTS": redirect all requests made over HTTP to HTTPS and add Strict-Transport-Security Header to all responses.
5. Commit your Change. The Delphix web application will restart.

The following is an example of how to set the Delphix Engine to accept HTTPS connections and redirect HTTP connections to HTTPS.

```
cd /service/httpConnector
update
set httpMode=HTTP_REDIRECT
commit
```

## Replacing the HTTPS (HTTP secure) certificate

This topic explains how to replace the HTTPS (HTTP Secure) certificate used by the Delphix Virtualization Engine. There are two methods of replacing the certificate. The key difference between the two is whether Delphix or the user is providing the key pair (public and private key).

### Delphix provided key pair

Use the following instructions to provide an HTTPS certificate chain for a key pair created by the Delphix Engine. Once the key pair is created users can download a Certificate Signing Request (CSR) to generate a signed certificate from the CA of their choice. This is done using the "create" operation in the "/service/tls/csr" API as seen below when using the CLI.

```
hostname.domainname> service tls csr
hostname.domainname service tls csr> create
hostname.domainname service tls csr create *> ls
Properties
  type: CertificateSigningRequestCreateParameters
  dname:
    type: X500DistinguishedNameComposite
    dname: (required)
  :
    type: EndEntityHttps
  forceReplace: false
  keyPair:
    type: RsaKeyPair
    keySize: 2048
    signatureAlgorithm: SHA256withRSA
```

The first key property is the dname. This will be used as the subject name of the CSR and resulting X.509 certificate unless it is changed when the certificate is signed. Delphix supports two different formats for dname:

- a composite string
- a list of fields

Use the composite string as follows:

```
hostname.domainname service tls csr create *> set dname.dname="CN=Delphix CA,
O=Delphix, C=US"
hostname.domainname service tls csr create *> ls
Properties
  type: CertificateSigningRequestCreateParameters
  dname:
    type: X500DistinguishedNameComposite (*)
    dname: CN=Delphix CA, O=Delphix, C=US (*)
```

Use the list of field formats as follows:

```
hostname.domainname service tls csr create *> set
dname.type=X500DistinguishedNameFields
hostname.domainname service tls csr create *> ls
Properties
```

```

type: CertificateSigningRequestCreateParameters
dname:
  type: X500DistinguishedNameFields (*)
  city: (unset)
  commonName: Delphix CA (*)
  country: US (*)
  organization: Delphix (*)
  organizationUnit: (unset)
  stateRegion: (unset)

```

The only required field is the commonName (CN).

The only currently supported type for endEntity is EndEntityHttps.

The next property is forceReplace. By default, this is false and means Delphix will not replace the active key pair and certificate with the newly generated keypair and self-signed certificate. If the user wants to replace the active key pair right away before the signed certificate has been created this can be set to true.

The final property keyPair impacts the generated key pair. When creating a new key pair the engine supports two algorithms:

- **RSA** - The supported signature algorithms are SHA256withRSA, SHA384withRSA, and SHA512withRSA . The valid key sizes range from 2048 to 4096.
- **ECDSA** - The supported signature algorithms are SHA256withECDSA, SHA384withECDSA, and SHA512withECDSA. The valid key sizes range from 256 to 571

Once the create operation has completed you can get the CSR in PEM format by selecting the CSR object and looking at the requestInPem property:

```

requestInPem: -----BEGIN CERTIFICATE REQUEST-----
MIIBezCB0gIBADAhMR8wHQYDVQDEZXiYmFrZXIuZGM5LmRlbHBoaXguY29tMIGn
MBAGByqGSM49AgEGBSuBBAAmA4GSAAQBU5WY9+GkCTFvbGHTNJDdb/QM3t4YI/9S6
fhCJELx7SbJNti2n0l3mCePenyUuBY9m6BwvUQzlhawZG5YAJ9WdcM+IIPciiNsD
Xmw0eFH05z6yTLMnfBYYZKFbpu/dcK5V8WoltrIC7jTxc/k6jf/WeD+dmyIMQ0Z7
VmwnD6RsaAs7T5lajXkurwPfqQ5MnsmgADAKBggqhkjOPQDAwOBlwAwgZMCSAGM
quqcnIAXIRDxQ+BzzSywNtozn5ihtfFxtTF/EW/ARBib2l9hq0pwHrIinnLvJw9u
avpAH1pkWHx1w0/06W6DCZAPIIL3ugJHKsScJqsvaeZzVqJVfQt8g42cL9hKc7ic
HLhuAyMGQOXrEdLbOxtOH6SiExnyEv2Y9LHHYYgRafgGz0oA5tx+mrkr9J+zm8Y=
-----END CERTIFICATE REQUEST-----

```

Once the CSR has been signed and turned into an X.509 Certificate you can replace the certificate using the "service/tls/endEntityCertificate" API. To replace using the CSR method begin by setting the correct type of replace parameters as seen below:

```

hostname.domainname service tls endEntityCertificate> replace
hostname.domainname service tls endEntityCertificate replace *> set
type=EndEntityCertificateReplaceChainParameters
hostname.domainname service tls endEntityCertificate replace *> ls
Properties
  type: EndEntityCertificateReplaceChainParameters
  chain:
    type: PemCertificateChain
    chain: (required)
  endEntity:

```

```
type: EndEntityHttps
```

The "chain" property must contain a list of the entire trust chain from the newly generated end-entity certificate to the root CA.

The CLI might not always interpret newline characters in PEM certificates correctly. Therefore, it is highly recommended to find and replace all newlines ('\n') with an empty string ('') prior to pasting the PEM certificate into the CLI.

To do this in the CLI first run:

```
hostname.domainname service tls endEntityCertificate replace * > edit chain.chain
Then `add` and `set contents` to the PEM certificate for each certificate in the
chain.
hostname.domainname service tls endEntityCertificate replace chain.chain * > add
```

When adding multiple certificates, use the command back after each add. After the final add, enter back and then commit.

The order in which the PEM certificates are added to the list does not matter.

Customer provided key pair

This section describes the steps to take if you are replacing the HTTPS with your own key pair and certificate.

1. To start, you need to add the key pair and full certificate chain as an entry in a file in JKS or PKCS #12 format.
2. Then, send a file upload request to the following endpoint:

```
hostname.domainname service tls endEntityCertificate
requestKeyPairAndCertChainUpload * > ls
Properties
  type: CertificateUploadParameters
  alias: alias_in_keystore (*)
  keypass: (unset)
  keystoreType: JKS
  storepass: ***** (*)
hostname.domainname service tls endEntityCertificate
requestKeyPairAndCertChainUpload * > commit
  type: FileUploadResult
  token: 8f4361c5-019c-4fee-9306-b7c85e977cf4
  url: /resources/json/delphix/data/upload
```

The **alias** field is where the key pair and certificate is saved in your JKS or PKCS #12 store.

The **keypass** field is the password for the given alias' key. If not set, it uses the keystore's password.

The **storepass** field is the keystore's password.

3. Then, establish a session from the host with the keystore to the Delphix Engine.

Choose the location of the cookies, and determine the API version (command example uses 1.9.2):

```
curl -c <path/to/cookies> -X POST --data '{ "type": "APISession", "version":
{ "type": "APIVersion", "major": 1, "minor": 9, "micro": 2 } }' -H "Content-
Type: application/json" http://<delphix_engine_url>/resources/json/delphix/
session
```

4. Login to the Delphix Engine using the established session as a domain or system admin:

```
curl -b <path/to/cookies> -X POST --data '{ "type": "LoginRequest", "username":
"sysadmin", "password": "sysadmin" }' -H "Content-Type: application/json" http://
<delphix_engine_url>/resources/json/delphix/login
```

5. Send the file upload request with the location of your keystore and token from above:

```
curl -b <path/to/cookies> -X POST -F "file=@<path/to/keystore>" -F
"token=8f4361c5-019c-4fee-9306-b7c85e977cf4" http://<delphix_engine_url>/
resources/json/delphix/data/upload
```

6. You can now replace the HTTPS end-entity certificate with the keystore you have uploaded, identified by the token:

```
hostname.domainname service tls endEntityCertificate replace *> set
type=EndEntityCertificateReplaceKeystoreParameters
hostname.domainname service tls endEntityCertificate replace *> set
token=8f4361c5-019c-4fee-9306-b7c85e977cf4
hostname.domainname service tls endEntityCertificate replace *> ls
Properties
  type: EndEntityCertificateReplaceKeystoreParameters (*)
  endEntity:
    type: EndEntityHttps

```

## CLI cookbook: configuring key-based SSH authentication for automation

This topic describes how to use CLI commands to configure individual users with SSH keys to allow for password-less authentication from a remote host to the CLI in an automated environment.

### What is SSH Key-based authentication?

Secure Shell (SSH) is a connection method used to log into UNIX or Linux servers remotely. With Delphix, it is used to connect to the Delphix Command Line Interface (CLI) from a remote computer. This normally requires a password on each connection; however, it is possible to use Key-based Authentication to avoid the password requirement and allow the automation of Delphix commands.

Key-based Authentication relies on a public/private key pair generated on the client system. The private key allows access to any server acknowledging the matching public key as being authorized to login. In order to configure this, a public/private key pair must be created, and the resulting public key should be added to the Delphix server using the CLI.

**⚠** The default domain user created on Delphix Engines is now admin instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling delphix\_admin.

### Procedure

1. Consult your client documentation for information on generating a public/private key pair. The `ssh-keygen` program is typical on UNIX platforms. If you need details on ssh-keygen usage or have unique requirements (such as named RSA keys), see [Third-Party SSH Key Generation Example](#). If you already have a public/private key pair generated on your system, you can skip to step 2.
2. Connect as the user you wish to configure or as a Delphix administrator.

**⚠ Warning:** When you connect to the Delphix Engine with the CLI, you should specify the appropriate namespace (either DOMAIN or SYSTEM). See [Connecting to the CLI](#) for more information.

3. Select the current user, or select a specific user if configuring another user as an administrator.

```
delphix> user current
```

4. Update the user and set the SSH key.

```
delphix user "admin"> update
delphix user "admin" update *> set publicKey="[PASTE KEY]"
delphix user "admin" update *> commit
delphix>
```

**⚠** Avoid Newline Characters with Public Key Entry The public key value, which can be quite long, must be entered as a single string with no newlines. When copying and pasting the public key, be sure to avoid introducing any newline characters. For more information on how to manage multiple public keys for password-less user authentication on Delphix, please visit this [Knowledge Base](#) article.

5. Verify you can authenticate through the Delphix CLI without a passphrase.  
Example Using Default SSH Key

```
ssh admin@DOMAIN@delphix-server.example.com
Last login: Thu Dec 13 22:16:28 2012 from 192.168.0.2
delphix>
```

Example Using a Non-default SSH Key File Located at path/to/delphix\_key

```
ssh -i path/to/delphix_key admin@DOMAIN@delphix-server.example.com
Last login: Thu Dec 13 22:16:28 2012 from 192.168.0.2
delphix>
```

## CLI cookbook: setting up SSH key authentication for UNIX environment users

This topic describes adding public-key authentication for a UNIX environment user, thus allowing the Delphix server to connect to your UNIX Environments without an explicit password. This method uses the Delphix CLI in order to set up the environment user and gather SSH keys.

UNIX host environments (and Oracle cluster environments) can have users configured to use SSH-key-based authentication instead of the traditional password authentication method.

### Prerequisites

- You must be able to log into the remote host (or all hosts of an Oracle cluster) and have write access to the `~/.ssh/authorized_keys` file within the desired user's home directory.

### Option 1: system key

Within Delphix, there is a per-system SSH public key that can be placed into the `~/.ssh/authorized_keys` file of the remote user. Once this has been done, the Delphix environment user can be configured to use the private key instead of an explicit password. Note that it is also possible to configure an environment to use this system key in the Delphix Management application by navigating to **Manage > Environments** and selecting **Public Key** as the **Login Type** for the environment. For details, see [Managing Environments](#).

1. Get the current system public key:

```
delphix> system get sshPublicKey
ssh-rsa
AAAAB3NzaC1yc2EAAAABIwAAAQEASE1M7uJX44LVpBljhnxB6MZUTx8VF6cupaVATg120lQonIqx29l
P+Mwp0AWh7C983IDoYDo+AY7RXpcFP9nKksiJnGSGiK6wo9RIiqSnF1x/
VXNkTt2/67RVofoiui4W5fuxD4h0IvoTr47Bg1hh9L6nhP0tnUvS/
rusHFJ+ogxGHm46mwNlgUJUGmLTNao+W0YU693HRLukEch01t4k6oLVGaC0eLjYlgBf0Z5XiIcBX6ZW
qVHAhwMinVjAvmfQhirAgCI7gYrd5/PwNL/DC8xyhWuxd2jgA7sSPeRqWY0JHt/
xcmdpIaPxTwtxQLKtNpxrFrQd+l4uf6LKxr5g7w== root@delphix
```

2. Add this key (starting with `ssh-rsa`) to the remote user's `~/.ssh/authorized_keys` file. You will need to get access to this file using an alternate authentication mechanism (such as logging in as the user with a password or logging in as an administrator). Depending on the target OS, you may need to do the following:
  - a. If the directory does not exist:

```
$ mkdir ~/.ssh
```

- b. If creating the file or directory as an administrator:

```
# chown -R <username> <home>/.ssh
```

- c. If required by the host SSH configuration, ensure the directory is not world-readable:

```
$ chmod 600 ~/.ssh/authorized_keys
$ chmod 755 ~
```

3. Create or edit an environment user:

```
delphix> environment user create
```

4. Set the user environment and name:

```
delphix environment user create *> set environment=environment1
delphix environment user create *> set name=username
```

5. Set the user credential type to `SystemKeyCredential` :

```
delphix environment user create *> set credential.type=SystemKeyCredential
```

6. Commit the results:

```
delphix environment user create *> commit
```

#### Option 2: Per-environment key pair

Each environment user can also be configured to use an SSH key pair provided via the CLI or API.

1. Add the public key to the remote user's `~/.ssh/authorized_keys` file. You will need to get access to this file using an alternate authentication mechanism (such as logging in as the user with a password or logging in as an administrator). Depending on the target OS, you may need to do the following:
  - a. If the directory does not exist:

```
$ mkdir ~/.ssh
```

- b. If creating the file or directory as an administrator:

```
# chown -R <username> <home>/.ssh
```

- c. If required by the host SSH configuration, ensure the directory is not world-readable:

```
$ chmod 600 ~/.ssh/authorized_keys
$ chmod 755 ~
```

2. Create or edit an environment user:

```
delphix> environment user create
```

3. Set the user environment and name:

```
delphix environment user create *> set environment=environment1
delphix environment user create *> set name=username
```

4. Set the user credential type to `KeyPairCredential` :

```
delphix environment user create *> set credential.type=KeyPairCredential
```

5. Set the private and public keys:

```
delphix environment user create *> set credential.privateKey="-----BEGIN ..."  
delphix environment user create *> set credential.publicKey="ssh-rsa AA..."
```

(these example values were trimmed for brevity)

6. Commit the results:

```
delphix environment user create *> commit
```

## CLI cookbook: configuring SSH host verification for UNIX environments

This topic describes how to configure SSH host verification when authenticating to UNIX environments, which lets the Delphix server ensure it connects to the intended environment hosts. This method uses the Delphix CLI to set the SSH key or fingerprint of each host. Currently, it is only possible to configure SSH host verification via the CLI or the Web Service API.

When an SSH key or fingerprint is specified for an environment host, the Delphix server will use it when connecting to that host to verify that host. If the key or fingerprint does not match the information presented by that host, the Delphix server will close that connection and report the problem to the user.

The key types supported by the Delphix server are `RSA` ( `ssh-rsa` ), `DSA` ( `ssh-dsa` ), `ECDSA` ( `ecdsa-sha2-nistp256` ) and `ED25519` ( `ssh-ed25519` ). The fingerprint types supported are `SHA256` and `SHA512` ; the `MD5` type is considered insecure and, therefore, is not supported.

### Prerequisites

- To obtain the SSH public key or fingerprint of a host remotely from another machine, you must have the `ssh-keyscan` and `ssh-keygen` utilities.
- To obtain the SSH public key or fingerprint directly from a host, you must be able to log into that host.

### Obtaining an SSH key or fingerprint

1. Remotely: List the SSH public keys of the host using the standard utility `ssh-keyscan` and choose one of them. For example:

```
$ ssh-keyscan example.environment.host # example.environment.host:22 SSH-2.0-OpenSSH_7.4 example.environment.host ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAQDBs0AAokSR067jI28syRmX0wY/fKIboLLu/
ofk6BzYLKtkMaK1QC78/6QleLIJUP5HdK8E7Um/iM1JMxry4h9Rl13onY0uJVZkDB9wnJiztSu/
Wl9Eqbt59TU1vGmp/4uLWS3PISl7bxs+l43HzsrjM4dT2efQ7sLWoW86CDlL7Je4va65/
aopvifxKZeZkT0srB3L8VzHKw9+NJOumy1CI3DIBiICURJd4WZ10IH5TFUDRaUFAC/trzW1gvJY/
Whp892tPHeKyP32h0ZNIc7oDPx2boZauJVR6/
BHMkpmLlhkPpEqfZP8JW+JNsNnLr9BEmwJXaEpwnua1BUi8F ...
```

where the key is the Base64-code string to the right of the key type. In this example, the RSA SSH public key is the string starting in "AAAAB3Nza" and ending in "a1BUi8F".

2. Alternatively, from the host: Log into the host and print the file contents of your public key of choice. For example:

```
$ cat /etc/ssh/ssh_host_rsa_key.pub ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAQDBs0AAokSR067jI28syRmX0wY/fKIboLLu/
ofk6BzYLKtkMaK1QC78/6QleLIJUP5HdK8E7Um/iM1JMxry4h9Rl13onY0uJVZkDB9wnJiztSu/
Wl9Eqbt59TU1vGmp/4uLWS3PISl7bxs+l43HzsrjM4dT2efQ7sLWoW86CDlL7Je4va65/
aopvifxKZeZkT0srB3L8VzHKw9+NJOumy1CI3DIBiICURJd4WZ10IH5TFUDRaUFAC/trzW1gvJY/
Whp892tPHeKyP32h0ZNIc7oDPx2boZauJVR6/
BHMkpmLlhkPpEqfZP8JW+JNsNnLr9BEmwJXaEpwnua1BUi8F
```

3. If a fingerprint is preferred, use `ssh-keygen` in conjunction with the above commands. For example, remotely:

```
$ ssh-keyscan example.environment.host | ssh-keygen -E sha256 -lf - ... 2048
SHA256:8Cx8cBg/pSbkId3uu2vATeugkAXcm+Ruu9hu660XEGI example.environment.host
(RSA) ...
```

where the fingerprint is "SHA256:8Cx8cBg/pSbkId3uu2vATeugkAXcm+Ruu9hu660XEGI" (the string between the key size and the hostname).

Alternatively, from the host:

```
$ cat /etc/ssh/ssh_host_rsa_key.pub | ssh-keygen -E sha256 -lf - 2048
SHA256:8Cx8cBg/pSbkId3uu2vATeugkAXcm+Ruu9hu660XEGI user@environment.host (RSA)
```

### Configuring SSH host verification during environment creation

The default SSH verification strategy is `SshAcceptAlways`, which always trusts the key or fingerprint presented by a remote host. The procedure to change this strategy to perform fingerprint-based host verification for single-host Unix environments is:

1. Set the new strategy to `SshVerifyFingerprint`:

```
delphix environment create * > edit hostParameters.host.sshVerificationStrategy
delphix environment create hostParameters.host.sshVerificationStrategy * > set
type=SshVerifyFingerprint
```

2. Set the key type and fingerprint type. For example:

```
delphix environment create hostParameters.host.sshVerificationStrategy * > set
keyType=RSA delphix environment create
hostParameters.host.sshVerificationStrategy * > set fingerprintType=SHA256
```

3. Set the fingerprint. For example:

```
delphix environment create hostParameters.host.sshVerificationStrategy * > set
fingerprint=SHA256:8Cx8cBg/pSbkId3uu2vATeugkAXcm+Ruu9hu660XEGI
```

4. Alternatively, you can specify the key itself using the `SshVerifyRawKey` strategy. For example:

```
delphix environment create hostParameters.host.sshVerificationStrategy * > set
type=SshVerifyRawKey delphix environment create
hostParameters.host.sshVerificationStrategy * > set keyType=RSA delphix
environment create hostParameters.host.sshVerificationStrategy * > set
rawKey=AAAAB3NzaC1yc2EAAAADAQABAAQDBs0AAokSR067jI28syRmX0wY/fKIboLLu/
ofk6BzYLtkMaK1QC78/6QlelIJUP5HdK8E7Um/iM1JMxry4h9Rl13onY0uJVZkDB9wnJiztSu/
Wl9Eqbt59TU1vGmp/4ulWS3PISl7bxs+l43HzsrjM4dT2efQ7sLWoW86CDlL7Je4va65/
aopvifxKZeZkT0srB3L8VzHKw9+NJOumy1CI3DIBiICURJd4WZ10IH5TFUDRaUFac/trzW1gvJY/
Whp892tPHeKyP32h0ZNIc7oDPx2boZauJVR6/
BHmKpmLlhkPpEqfZP8JW+JNsNnLr9BEmwJXaEpwnua1BUii8F
```

5. When you are done specifying all other environment creation parameters, create the environment:

```
delphix environment create * > commit
```

6. If you are creating a Unix cluster, the procedure to start editing the SSH verification settings for the first node in that cluster is similar to the single-host case. For example:

```
delphix> environment create delphix environment create * > set
type=OracleClusterCreateParameters delphix environment create * > edit nodes
delphix environment create nodes * > add delphix environment create nodes 0 * >
edit delphix environment create nodes 0 * > edit
hostParameters.host.sshVerificationStrategy # configure SSH verification
settings
```

Note that only one node (host) can be specified and configured when creating a Unix cluster environment. The SSH verification settings for the remaining hosts can only be specified afterward by editing them via " `host select <hostname> update` ", once the corresponding nodes have been discovered or added. See the next section.

#### Configuring SSH host verification for existing hosts

For any Unix environment host, whether it is single or part of a cluster, you can set up or change its configuration for SSH verification after the environment has been added by editing the host. For example:

```
delphix> host select example.environment.host update sshVerificationStrategy delphix
host 'example.environment.host' update sshVerificationStrategy * > edit
sshVerificationStrategy # configure SSH verification settings
```

#### Testing SSH host verification

It is possible to configure an SSH key or fingerprint when performing a connectivity test to a Unix host. This can be done without even creating an environment for that host. For example:

```
delphix> connectivity ssh # configure address and credentials ... delphix
connectivity ssh * > edit sshVerificationStrategy # configure SSH verification
settings
```

#### SSH host verification errors

When the Delphix server initiates an SSH connection to a host, if SSH host verification is configured (i.e. the verification strategy is not the default `SshAcceptAlways` ), the server will first check the key presented by the host. Only if this check passes, the server will attempt to authenticate. Therefore, a host key verification failure will be reported as "Unrecognized key or fingerprint" to the user before any authentication failure. For example:

```
delphix connectivity ssh * > set credentials.password=<BAD PASSWORD> delphix
connectivity ssh * > set sshVerificationStrategy.rawKey=<BAD KEY> delphix connectivity
ssh * > commit Error: Unrecognized key or fingerprint returned by host
"example.environment.host". Action: Contact your administrator as this could be a
```

man-in-the-middle attack. Otherwise, correct the host's ssh key/fingerprint configuration. delphix connectivity ssh \*> set sshVerificationStrategy.rawKey=<GOOD KEY> delphix connectivity ssh \*> commit Error: Unable to authenticate to host "example.environment.host" using username "myusername". Action: Check the username and password and **try** again.

## CLI cookbook: system administration

These topics describe various system administration tasks that can be performed with the command-line interface, such as changing the name of the <default> group and setting up network connectivity.

This section covers the following topics:

- [CLI cookbook: setting NFS version](#)
- [CLI cookbook: configuring a second network interface](#)
- [Removing IP addresses from a network interface](#)
- [CLI cookbook: adding a static route](#)
- [CLI cookbook: changing the default group name](#)
- [CLI cookbook: how to change a Delphix user password](#)
- [CLI cookbook: retrieve capacity information](#)
- [CLI cookbook: view storage test results](#)
- [CLI cookbook: how to change IP Address of Delphix engine](#)
- [CLI cookbook: about alert notifications](#)
- [CLI cookbook: obtaining CPU performance information using CLI](#)
- [CLI cookbook: rebooting the Delphix engine via CLI](#)
- [CLI cookbook: disabling user-click analytics](#)
- [CLI cookbook: changing the API version](#)

## CLI cookbook: setting NFS version

This topic describes how to configure the NFS version used for mounting VDBs.

## Procedure

1. Log in to the Delphix Engine as the sysadmin user and switch to the Service NFS context. Then use the `list` command to view the current configuration.

```
delphix service nfs> list
Properties
  type: NfsConfig
  mountVersion: Automatic
```

2. Run the `update` command and configure the version (Options are Automatic, NFSv3, and NFSv4)

```
delphix service nfs> update
delphix service nfs update *> set mountVersion=NFSv4
```

3. Commit the operation.

```
delphix service nfs update *> commit
ip-10-110-212-129 service nfs> list
Properties
  type: NfsConfig
  mountVersion: NFSv4
```

## CLI cookbook: configuring a second network interface

This topic describes how to configure a static IP address on a second network interface.

## Procedure

1. Add a NIC to the Delphix virtual machine. The specific procedure will depend on the platform. For example, on VMware, a VMXNET3 virtual network adapter can be added dynamically from vSphere or other administrative interfaces, and the Delphix Engine will recognize the new NIC without a reboot. On other platforms, a reboot may be required for the Delphix Engine to recognize the new virtual hardware.
2. Log in to the Delphix Engine as the sysadmin user and switch to the network interface context. Then use the `list` command to view the available network interfaces, and select the new interface to be configured.

```
delphix network interface> list
NAME
vmxnet3s0
vmxnet3s1
delphix network interface> select vmxnet3s1
delphix network interface "vmxnet3s1"> get
  type: NetworkInterface
  name: vmxnet3s1
  addresses: (empty)
  device: vmxnet3s1
  macAddress: 0:c:29:e5:4c:c1
  mtu: 1500
  mtuRange: 60-9000
  reference: NETWORK_INTERFACE-vmxnet3s1
  state: DOWN
```

3. Run the `update` command and configure a static address.

```
delphix network interface "vmxnet3s1"> update
delphix network interface "vmxnet3s1" update *> edit addresses.0
delphix network interface "vmxnet3s1" update addresses.0 *> set address=10.1.2.3/24
delphix network interface "vmxnet3s1" update addresses.0 *> get
  type: InterfaceAddress (*)
  address: 10.1.2.3/24 (*)
  addressType: STATIC (*)
```

4. Commit the operation.

```
delphix network interface "vmxnet3s1" update addresses.0 *> commit
delphix network interface "vmxnet3s1"> get
  type: NetworkInterface
  name: vmxnet3s1
  addresses:
    0:
```

```
type: InterfaceAddress
address: 10.1.2.3/24
addressType: STATIC
state: OK
device: vmxnet3s1
macAddress: 0:c:29:e5:4c:c1
mtu: 1500
mtuRange: 60-9000
reference: NETWORK_INTERFACE-vmxnet3s1
state: OK
```

## Removing IP addresses from a network interface

This topic describes how to remove one or more IP addresses from a network interface.

### Removing all IP addresses

#### Procedure

1. Log in to the Delphix Engine as the sysadmin user and switch to the network interface context. Then use the `list` command to view the available network interfaces, and select the interface.

```
delphix> network interface
delphix network interface> list
NAME      MACADDRESS      MTU
ens160    02:dc:02:00:7f:06 1500
delphix network interface> select ens160
delphix network interface 'ens160'> get
  type: NetworkInterface
  name: ens160
  addresses:
    0:
      type: InterfaceAddress
      address: 10.43.70.135/16
      addressType: DHCP
      enableSSH: true
      sessionInUse: false
      state: OK
  device: ens160
  macAddress: 02:dc:02:00:7f:06
  mtu: 1500
  mtuRange: 68-9000
  reference: NETWORK_INTERFACE-ens160
  state: OK
```

2. Run the `update` command and unset the addresses property to remove all addresses. Note that in this example, we only had one address to remove, but this procedure removes all addresses even if more than one were configured.

```
delphix network interface 'ens160'> update
delphix network interface 'ens160' update *> unset addresses
delphix network interface 'ens160' update *> get
  type: NetworkInterface
  name: ens160
  addresses: (unset) (*)
  mtu: 1500
```

3. `Commit` the operation.

```
delphix network interface 'ens160' update *> commit
```

```
delphix network interface 'ens160'> get
type: NetworkInterface
name: ens160
addresses: (empty)
device: ens160
macAddress: 02:dc:02:00:7f:06
mtu: 1500
mtuRange: 68-9000
reference: NETWORK_INTERFACE-ens160
state: OK
```

### Removing a specific IP address

1. Log in to the Delphix Engine as the sysadmin user and switch to the network interface context. Then use the `list` command to view the available network interfaces, and select the interface. Note that in this example, there are two addresses, a static address, and a DHCP address.

```
delphix> network interface
delphix network interface> list
NAME      MACADDRESS      MTU
ens160    02:dc:02:00:7f:06 1500
delphix network interface> select ens160
delphix network interface 'ens160'> get
type: NetworkInterface
name: ens160
addresses:
  0:
    type: InterfaceAddress
    address: 10.11.12.13/24
    addressType: STATIC
    enableSSH: true
    sessionInUse: false
    state: OK
  1:
    type: InterfaceAddress
    address: 10.43.70.135/16
    addressType: DHCP
    enableSSH: true
    sessionInUse: false
    state: OK
device: ens160
macAddress: 02:dc:02:00:7f:06
mtu: 1500
mtuRange: 68-9000
reference: NETWORK_INTERFACE-ens160
state: OK
```

2. Run the `update` command and unset one of the addresses. In this example, only the static address is removed, retaining the DHCP address.

```

delphix network interface 'ens160'> update
delphix network interface 'ens160' update *> get
  type: NetworkInterface
  name: ens160
  addresses:
    0:
      type: InterfaceAddress
      address: 10.11.12.13/24
      addressType: STATIC
      enableSSH: true
    1:
      type: InterfaceAddress
      address: 10.43.70.135/16
      addressType: DHCP
      enableSSH: true
  mtu: 1500
delphix network interface 'ens160' update *> unset addresses.0
delphix network interface 'ens160' update *> get
  type: NetworkInterface
  name: ens160
  addresses:
    0:
      type: InterfaceAddress (*)
      address: 10.43.70.135/16 (*)
      addressType: DHCP (*)
      enableSSH: true (*)
  mtu: 1500

```

### 3. Commit the operation.

```

delphix network interface 'ens160' update *> commit
delphix network interface 'ens160'> get
  type: NetworkInterface
  name: ens160
  addresses:
    0:
      type: InterfaceAddress
      address: 10.43.70.135/16
      addressType: DHCP
      enableSSH: true
      sessionInUse: false
      state: OK
  device: ens160
  macAddress: 02:dc:02:00:7f:06
  mtu: 1500
  mtuRange: 68-9000
  reference: NETWORK_INTERFACE-ens160
  state: OK

```

## CLI cookbook: adding a static route

This topic describes how to add a static route.

## Procedure

1. Log in to the Delphix Engine as the sysadmin user and switch to the network route context.

```
delphix network route> list
DESTINATION      GATEWAY      OUTINTERFACE  PROTOCOL
default         172.16.0.1   ens192        DHCP
10.1.2.0/24      -            ens224        KERNEL
172.16.0.0/24    -            ens192        KERNEL
```

2. Run the `create` command to add a new route.

```
delphix network route> create
delphix network route create *> set destination=192.168.11.0/24
delphix network route create *> set gateway=10.1.2.1
delphix network route create *> get
  type: NetworkRoute
  destination: 192.168.11.0/24 (*)
  gateway: 10.1.2.1 (*)
  outInterface: (unset)
```

3. Optional outInterface Property Setting the `outInterface` property is optional, as the system will automatically determine the output interface based on the gateway address provided, as shown below.
4. `Commit` the operation.

```
delphix network route create *> commit
delphix network route> list
DESTINATION      GATEWAY      OUTINTERFACE  PROTOCOL

## CLI cookbook: changing the default group name

This topic describes how to change the name of the default group <New Group> on the Delphix Engine as a simple example of CLI interactions. You must have delphix\_admin credentials to perform this procedure.

### Procedure

1. Switch to the group context and list groups on the system.

```
delphix> group
delphix group> list
NAME          DESCRIPTION
<New Group>  -
```

2. Select the default group and show current properties.

```
delphix group> select ""
delphix group ""> get
name: <New Group>
type: Group
description: (unset)
reference: GROUP-1
```

3. Run the `update` command and set the name.

```
delphix group ""> update
delphix group "" update *> set name=default
delphix group "" update *> get
name: default (*)
type: Group
description: (unset)
reference: GROUP-1
```

4. `Commit` the operation.

```
delphix group "" update *> commit
delphix group "default">
```

## CLI cookbook: how to change a Delphix user password

**⚠** The default domain user created on Delphix Engines is now admin instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling delphix\_admin.

1. ssh into your engine with a user that has Admin privileges.

```
ssh admin@delphix
```

2. Go to Users and select the User you would like to change the password of.

```
delphix > user
delphix user > ls
delphix user > select example_user
delphix user "example_user" > ls
```

3. Select `updateCredential` to allow you to change the password and set a new password.

```
delphix user "example user" > updateCredential
delphix user "example_user" updateCredential *> set newCredential.password=<new
password>
```

4. Commit the operation.

```
delphix user "example_user" updateCredential *> commit
```

Example:

```
ssh admin@delphixengine
delphixengine > user
delphixengine user > ls

Objects

NAME                EMAILADDRESS
-----
sysadmin            -
admin               no@delphix.com
test_user           no@delphix.com

Operations
```

```
create
```

```
current
```

```
delphixengine user > select test_user
```

```
delphixengine user "test_user" > ls
```

```
Properties
```

```
  type: User
```

```
  name: test_user
```

```
  authenticationType: NATIVE
```

```
  credential:
```

```
    type: PasswordCredential
```

```
    password: *****
```

```
  emailAddress: no@delphix.com
```

```
  enabled: true
```

```
  firstName: (unset)
```

```
  homePhoneNumber: (unset)
```

```
  isDefault: true
```

```
  lastName: (unset)
```

```
  locale: en_US
```

```
  mobilePhoneNumber: (unset)
```

```
  passwordUpdateRequested: false
```

```
  principal: test_user
```

```
  publicKey: (unset)
```

```
  reference: USER-2
```

```
  sessionTimeout: 30min
```

```
  userType: DOMAIN
```

```
  workPhoneNumber: (unset)
```

Operations

delete

update

disable

enable

updateCredential

```
delphixengine user "test_user" > updateCredential
```

```
delphixengine user "test_user" updateCredential *> set newCredential.password=<n  
ew password>
```

```
delphixengine user "test_user" update *> commit
```

## CLI cookbook: retrieve capacity information

This topic describes how to gather capacity information from your Delphix Engine. This information includes:

- dSource Space Breakdown
- Virtual Object Space Breakdown
- Total Space

### Procedure

1. Switch to the capacity system context.

```
delphix> capacity system
```

2. List the properties of this content.

```
delphix capacity system> ls
Properties
type: CurrentSystemCapacityData
source:
type: CapacityBreakdown
activeSpace: 940582400B
actualSpace: 1075381760B
descendantSpace: 134583808B
logSpace: 145920B
manualSpace: 0B
policySpace: 0B
syncSpace: 134583808B
timeflowUnvirtualizedSpace: 7725215744B
unvirtualizedSpace: 2624235520B
timestamp: 2015-12-11T11:49:18.998Z
totalSpace: 25568477184B
virtual:
type: CapacityBreakdown
activeSpace: 176684032B
actualSpace: 313768448B

logSpace: 47820288B
manualSpace: 85958144B
policySpace: 0B
syncSpace: 85958144B
timeflowUnvirtualizedSpace: 5475587584B
unvirtualizedSpace: 2667149312B
```

For more information about capacity management in Delphix, visit [An Overview of Capacity and Performance Information](#)

## CLI cookbook: view storage test results

1. Log into the CLI as the sysadmin.

```
ssh sysadmin@yourengine
```

2. Navigate to storage test.

```
delphix > storage  
delphix storage > test
```

3. List your tests and select the one that you would like to view and get the results.

```
delphix storage test > ls  
delphix storage test > select STORAGE_TEST-X  
delphix storage test STORAGE_TEST-X > result  
delphix storage test STORAGE_TEST-X result *> commit
```

## CLI cookbook: how to change IP address of Delphix Engine

This topic describes how to change an IP address on the Delphix Engine.

## Procedure

1. Stop all running VDBs by clicking the **Stop** button on the VDB card.
2. Disable all dSources.
3. Log into the Delphix Engine as **sysadmin** user and switch to the network interface context. Then use the list command to view the available network interfaces, and select the public interface to be changed.

```
delphix> network
delphix network> setup
delphix network interface> list
NAME
vmxnet3s0
delphix network interface> select vmxnet3s0
delphix network interface 'vmxnet3s0'> get
  type: NetworkInterface
  name: vmxnet3s0
  addresses:
    0:
      type: InterfaceAddress
      address: 10.1.2.3/24
      addressType: STATIC
      enableSSH: true
      state: OK
  dataNode: DATA_NODE-34
  device: vmxnet3s0
  macAddress: 0:c:29:32:96:a3
  mtu: 1500
  mtuRange: 60-9000
  reference: NETWORK_INTERFACE-vmxnet3s0-DATA_NODE-34
  state: OK
```

4. Run the update command and update the address to the new IP address.

```
delphix network interface 'vmxnet3s0'> update
delphix network interface 'vmxnet3s0' update *> edit addresses.0
delphix network interface 'vmxnet3s0' update addresses.0 *> get
Properties
  type: InterfaceAddress
  address: 172.16.151.154/24
  addressType: STATIC
  enableSSH: true

delphix network interface 'vmxnet3s0' update addresses.0 *> set address=10.1.2.
4/24
delphix network interface 'vmxnet3s0' update addresses.0 *> get
  type: InterfaceAddress (*)
  address: 10.1.2.4/24 (*)
```

```
addressType: STATIC (*)  
enableSSH: true (*)
```

5. Commit the operation.

```
delphix network interface 'vmxnet3s0' update addresses.0 *> commit  
delphix network interface 'vmxnet3s0'> get  
  type: NetworkInterface  
  name: vmxnet3s0  
  addresses:  
    0:  
      type: InterfaceAddress  
      address: 10.1.2.4/24  
      addressType: STATIC  
      enableSSH: true  
      state: OK  
  dataNode: DATA_NODE-34  
  device: vmxnet3s0  
  macAddress: 0:c:29:32:96:a3  
  mtu: 1500  
  mtuRange: 60-9000  
  reference: NETWORK_INTERFACE-vmxnet3s0-DATA_NODE-34  
  state: OK
```

6. Re-enable the VDBs and dSources running from the engine.

CLI cookbook: about alert notifications

The Delphix Engine can send out email notifications when alerts happen. Alert profiles control this functionality.

An alert profile is composed of two things:

- **Filter specification:** A filter, or combination of filters, that specifies which alerts are of interest.
- **Alert action:** This specifies the email addresses to which the Delphix Engine will send an email when an alert matches the filter specification.

By default, the Delphix Engine has a single alert profile configured with the following parameters:

- Filter Specification: Match any alert with a severity level of **CRITICAL** or **WARNING**.
- Alert Actions: Send an email to the address defined for user **admin**.

 The default domain user created on Delphix Engines is now admin instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling delphix\_admin.

Using the CLI, it is possible to:

- Modify the system default alert profile
- Create additional profiles in addition to the default one
- Set multiple actions for a single profile, such as "email delphix\_admin" and "email user1@mycompany.com"

Simple filters

- Filtered by Owner of alerts target – for example, objects owned by user 1

### Complex filters

Complex filters combine/modify other sub-filters:

- “And” filter – Used when all conditions defined must be met for the filter to notify the user with an email
- “Or” filter – Used when either one or the other of the conditions defined in the filters must be met for the filter to notify the user with an email
- “Not” filter – Used to exclude items

Limitations

- This is a CLI feature.
- Alert Profiles do not override permission settings. If you do not have Read permission on an object then your alert profile will never get triggered for that object's alerts, regardless of your filter settings.

The following CLI examples will run through how to create these three filters. Each example provides three different methods of setting up a profile. These include the following:

- A simple profile
- A profile with two filters
- A complicated profile

For more information, see [CLI Cookbook: creating alert profiles](#)

A simple profile

A simple profile approach matches the Delphix out-of-the-box default alert profiles. To create a simple alert profile using the CLI as seen in the figure below, go into the alert profile section of the command-line interface (CLI) and create a new profile. Line four prompts the engine to send an email when the filters are triggered. The following

three command lines refer to the filter specifications. Follow two severity levels: warning and critical. This will trigger an email alert when any warning or critical events occur.

```
twalsh-trunk.dcenter> cd alert
twalsh-trunk.dcenter alert> cd profile
twalsh-trunk.dcenter alert profile> create
twalsh-trunk.dcenter alert profile create *> set actions.0.type=AlertActionEmailUser
twalsh-trunk.dcenter alert profile create *> set filterSpec.type=SeverityFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.severityLevels.0=CRITICAL
twalsh-trunk.dcenter alert profile create *> set filterSpec.severityLevels.1=WARNING
twalsh-trunk.dcenter alert profile create *> commit
```

```
twalsh-trunk.dcenter> cd alert
twalsh-trunk.dcenter alert> cd profile
twalsh-trunk.dcenter alert profile> create
twalsh-trunk.dcenter alert profile create *> set actions.0.type=AlertActionEmailUser
twalsh-trunk.dcenter alert profile create *> set filterSpec.type=SeverityFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.severityLevels.0=CRITICAL
twalsh-trunk.dcenter alert profile create *> set filterSpec.severityLevels.1=WARNING
twalsh-trunk.dcenter alert profile create *> commit
```

*Simple alert profile example in the CLI*

A compound alert profile

Creating a compound alert profile in the CLI will combine two filters together. This profile triggers an email about any alert on objects owned by the delphix\_admin plus any other alert that is critical. The compound alert profile creates two filters. The first one will be the target owner filter, which in this case is **admin**. The second filter is the severity filter, allowing users to match anything that is critical. Combine these two filters using the OR logic so that if any of the sub-filters match, the whole filter matches. An example of this can be seen in the figure below.

*Alert profile using OR logic*

While working in the CLI, the first four lines describe a simple alert profile. The distinction between simple and compound alert profiles is that in a compound profile, the top-level filter uses an OR filter with sub-filters for target owner and severity level, as seen in line five of the figure below.

*A compound alert profile*

Complex alert profile

A complex alert profile uses the profile filter created in the compound alert profile and modifies it. For the example shown in the figure below, you have a VDB named test\_instance that you do not need any emails about. The following commands will create an effective filter.

1. Create an OR filter with two sub filters: target owner and event type.
2. Create a NOT filter which will exclude the VDB (test\_instance) from which you do not want to receive notifications.
3. Use the AND logic to combine all these filters together, as seen below.

*Complex alert profile*

Below is an example of the command lines used to set up this complex profile.

```
twalsh-trunk.dcenter> cd alert
twalsh-trunk.dcenter alert> cd profile
twalsh-trunk.dcenter alert profile> create
twalsh-trunk.dcenter alert profile create *> set actions.0.type=AlertActionEmailUser
twalsh-trunk.dcenter alert profile create *> set filterSpec.type=AndFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.0.type=NotFilter
twalsh-trunk.dcenter alert profile create *> edit filterSpec.subFilters.0.subFilter
twalsh-trunk.dcenter alert profile create filterSpec.subFilters.0.subFilter *> set type=TargetFilter
twalsh-trunk.dcenter alert profile create filterSpec.subFilters.0.subFilter *> set targets.0=test_instance
twalsh-trunk.dcenter alert profile create filterSpec.subFilters.0.subFilter *> back
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.1.type=OrFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.1.subFilters.0.type=TargetOwnerFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.1.subFilters.0.owners.0=delphix_admin
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.1.subFilters.1.type=SeverityFilter
twalsh-trunk.dcenter alert profile create *> set filterSpec.subFilters.1.subFilters.1.severityLevels=CRITICAL
twalsh-trunk.dcenter alert profile create *> commit
```

*Complex alert profile CLI*

## CLI cookbook: creating alert profiles

This article describes how to create alert profiles.

Delphix generates alerts for different events. Users may want to be notified of events based on certain criteria such as the type of event or severity. An alert profile allows a user or group of users to be notified of the desired event.

**⚠** The default domain user created on Delphix Engines is now admin instead of delphix\_admin. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling delphix\_admin.

### Procedure

1. ssh into your engine using your delphix\_admin username and password.

```
ssh admin@yourdelphixengine
```

2. Go into your alerts and list the alerts you already have.

```
delphix > alert
delphix alert > ls
```

3. Create your profile.

```
delphix alert > profile
delphix alert profile > create
delphix alert profile create * > ls
```

4. Set Actions and Severity Filter.

### **⚠** Valid Values for Parameters

actions.0.type:

1. AlertActionEmailList: This type of alert is used to create an alert for any number of users. When this type is selected, an email address may be defined in each element of the "actions.0.addresses" array as illustrated above.
2. AlertActionEmailUser: This type of alert is created for the email address of the user currently logged into the command-line interface. The "actions.0.addresses" array is not available for this type.

actions.0.filterSpec.severityLevels:

1. INFORMATIONAL
2. WARNING
3. CRITICAL
4. AUDIT

```
delphix alert profile create *> set actions.0.type=<AlertActionEmailList or
AlertActionEmailUser>
delphix alert profile create *> set actions.0.addresses.0=<email address to send to>
delphix alert profile create *> set actions.0.addresses.1=<additional email address>
```

```
delphix alert profile create *> set actions.0.addresses.2=<additional email address>
delphix alert profile create *> ls
```

**\*\*Prior to Delphix Engine version 5.1**

```
delphix alert profile create *> set severityFilter=
delphix alert profile create *> set severityFilter=<AUDIT|WARNING|CRITICAL|
INFORMATIONAL>
```

**\*\*Delphix Engine version 5.1 and beyond**

```
set filterSpec.severityLevels=<AUDIT|WARNING|CRITICAL|INFORMATIONAL>
```

#### 5. Commit your changes.

```
delphix alert profile create *> commit
```

#### Example

```
ssh admin@yourengine
delphix > alert
delphix alert> ls
Objects

  severityFilter: CRITICAL,WARNING

```

```

    targetFilter: (empty)
Operations
delete
update
delphix alert profile> create
delphix alert profile create *> set actions.0.type=AlertActionEmailList
delphix alert profile create *> set actions.0.addresses.0=johndoe@acme.com
delphix alert profile create *> set actions.0.addresses.1=samsmith@acme.com
delphix alert profile create *> set filterSpec.severityLevels=INFORMATIONAL

```

\*The last piece of the alert profile that needs to be configured is the "targetFilter". This is an array so you can define multiple targets. In the following example, there is a dSource named "pubs2" the user wants to define an alert on. If they try to set the filter to just the name of the dSource itself ("pubs2"), it will warn them that this is ambiguous and gives a hint on how to fully qualify it:

```

delphix > alert profile create
delphix alert profile create *> ls
Properties
  type: AlertProfile
  actions:
    0:
      type: AlertActionEmailList (*)
      addresses: foo@bar.com (*)
      format: HTML (*)
      filterSpec: (unset)
delphix alert profile create *> edit actions
delphix alert profile create actions *> add
delphix alert profile create actions 0 *> set addresses=foo@bar.com
delphix alert profile create actions 0 *> back
delphix alert profile create actions *> back
delphix alert profile create *> set filterSpec.severityLevels=WARNING
delphix alert profile create *> set filterSpec.type=TargetFilter
delphix alert profile create *> set filterSpec.targets="REPLICATION_SPEC_EXECUTE"
delphix alert profile create *> commit

```

Use the tab button freely to autocomplete and also see available options, for instance, while changing the severityLevels property, you can use the tab key like so:

```

DELPHIX-4221.dcenter alert profile 'ALERT_PROFILE-1' update *> set
filterSpec.severityLevels= <I HIT TAB HERE TO SEE OPTIONS BELOW>

```

```

AUDIT          CRITICAL          INFORMATIONAL  WARNING

```

#### Note on names used in the example

SRC\_157\_4K: Repository (entity containing the database instances)

ASE: Group name

pubs2: Name of an individual database instance

The user sets the target filter to be equal to "pubs2/pubs2" and "ASE/pubs2" because if you review the "TARGETNAME" column from step 1 above, you will see alerts generated for both of these targets.

## CLI cookbook: obtaining CPU performance information using CLI

There are times when it may be desirable to obtain analytics information about the Delphix Engine CPU, which is formatted differently than what is available from the Delphix User Interface (UI).

### Troubleshooting

You can obtain running information by looking at the **GUI > Resources > Performance Analytics**. You will see the graph for CPU if the CPU is selected.

When logged into the Delphix Engine command-line interface (CLI) as `delphix_admin`, you can see the default analytics gathered:

```
dlpx5120.dcenter> analytics
dlpx5120.dcenter analytics> list
NAME STATISTICSTATE STATE COLLECTIONINTERVAL COLLECTIONAXES
default.cpu CPU_UTIL RUNNING 1sec idle,kernel,user
default.disk DISK_OPS RUNNING 1sec op,avgLatency,latency,count,throughput
default.iscsi iSCSI_OPS RUNNING 1sec op,latency,count,throughput
default.network NETWORK_INTERFACE_UTIL RUNNING 1sec
outBytes,networkInterface,inPackets,inBytes,outPackets
default.nfs NFS_OPS RUNNING 1sec op,latency,count,throughput
default.tcp TCP_STATS RUNNING 1sec
congestionWindowSize,localPort,remotePort,receiveWindowSize,inUnorderedBytes,s
endWindowSize,retransmittedBytes,outBytes,localAddress,roundTripTime,inBytes,u
nacknowledgedBytes,remoteAddress
```

### Resolution

You can also obtain some information from the CLI, using the [Performance Analytics Tool API Reference](#).

In order to view this information, you must log in with a user that had Delphix Admin privileges.

#### Option 1: Running an Existing Analytic

1. Login as admin and run `analytics`.

```

dlpx5120.dcenter> analytics
dlpx5120.dcenter analytics> list
NAME STATISTICTYPE STATE COLLECTIONINTERVAL COLLECTIONAXES
default.cpu CPU_UTIL RUNNING 1sec idle,kernel,user
default.disk DISK_OPS RUNNING 1sec op,avgLatency,latency,count,throughput
default.iscsi iSCSI_OPS RUNNING 1sec op,latency,count,throughput
default.network NETWORK_INTERFACE_UTIL RUNNING 1sec
outBytes,networkInterface,inPackets,inBytes,outPackets
default.nfs NFS_OPS RUNNING 1sec op,latency,count,throughput
default.tcp TCP_STATS RUNNING 1sec
congestionWindowSize,localPort,remotePort,receiveWindowSize,inUnorderedBytes,s
endWindowSize,retransmittedBytes,outBytes,localAddress,roundTripTime,inBytes,u
nacknowledgedBytes,remoteAddress

Children
statistic

Operations
create

```

2. To see the available properties for CPU analytics, `select` and list the `default.cpu`.

```
dlpx5120.dcenter analytics> select default.cpu
dlpx5120.dcenter analytics 'default.cpu'> ls
Properties
  type: StatisticSlice
  name: default.cpu
  axisConstraints: (empty)
  collectionAxes: idle, kernel, user
  collectionInterval: 1sec
  dataNode: DATA_NODE-1
  reference: ANALYTICS_STATISTIC_SLICE-1
  state: RUNNING
  statisticType: CPU_UTIL

Operations
  delete
  getData
  pause
  rememberRange
  resume
  stopRememberingRange
```

3. Specify `setopt trace=true` in order to see the `CpuUtilDatapointStream` datapoints.

```

dlpx5120.dcenter analytics 'default.cpu'> setopt trace=true

Option 2: Creating a New Analytic

1. Log in as admin and then run `analytics`
2. Run `create` and `list` the properties.

```
dlpx5120.dcenter analytics> create
dlpx5120.dcenter analytics create *> ls
Properties
  type: StatisticSlice
  name: (required)
  axisConstraints: (unset)
  collectionAxes: (required)
  collectionInterval: (unset)
  dataNode: (unset)
  statisticType: (required)
```

3. Set the required Properties `name` , `collectionAxes` and `statisticType` (if you are unsure you can run `help for options`) `for=""> for options>`

```
set name=test.cpu
set collectionAxes=kernel
set statisticType=CPU_UTIL

dlpx5120.dcenter analytics create *> ls
Properties
  type: StatisticSlice
  name: test.cpu
  axisConstraints: (unset)
  collectionAxes: kernel
  collectionInterval: (unset)
  dataNode: (unset)
  statisticType: CPU_UTIL
```

4. Commit to being data collection.

```
dlpx5120.dcenter analytics create *> commit

=== POST /resources/json/delphix/analytics ===
{
  "type": "StatisticSlice",
  "name": "test.cpu",
  "collectionAxes": [
    "kernel"
  ],
  "statisticType": "CPU_UTIL"
}
=== RESPONSE ===
{
  "type": "OKResult",
  "status": "OK",
  "result": "ANALYTICS_STATISTIC_SLICE-7",
  "job": null,
  "action": "ACTION-656"
}
=== END ===
`ANALYTICS_STATISTIC_SLICE-7
```

5. Use `ls` to see the new `test.cpu` analytic

```
dlpx5120.dcenter analytics> ls
```

```

## CLI cookbook: rebooting the Delphix engine via CLI

Occasionally, the management stack will hang on the GUI, or routine maintenance will require a reboot of the Delphix Engine. You can do this safely through either the Delphix Setup or CLI. Before performing a reboot, it is important that all your VDBs are shut down and dSources disabled in order to maintain data integrity.

### Prerequisites

- Shut down all VDBS
- Shut down dSources

### Procedure

Complete the following steps to reboot the Delphix Engine via CLI:

1. Login to the CLI using the sysadmin **username** and **password**.

```
ssh sysadmin@yourdelphixengine
```

2. Go to **system > reboot**.

```
delphix > system  
delphix system > reboot
```

3. Commit the action.

```
delphix system reboot *> commit
```

## CLI cookbook: disabling user-click analytics

The Delphix User-click Analytics feature is a lightweight method to capture how users interact with Delphix product user interfaces. The goal of capturing this data is to get a better understanding of product usage, engagement, and user behavior, and to use this data to improve Delphix products and customer experience. This feature is enabled by default for customers deploying on or upgrading to this version. User-click Analytics may also be disabled via the UI.

 This procedure will disable user-click analytics on both the Delphix Engine and Delphix Self-Service.

### Procedure to disable user-click analytics

1. ssh into your engine with a user that has Admin privileges.

```
ssh sysadmin@delphix
```

2. Go to Services and select the userInterface.

```
delphix > cd service  
delphix service > cd userInterface
```

3. Update the analyticsEnabled option to false.

```
delphix service userInterface > ls  
Properties  
  Type userInterfaceConfig  
  analyticsenabled: true  
Operations  
delphix service userInterface > update  
delphix service userInterface update *> set analyticsEnabled=false  
delphix service userInterface update *> commit
```

## CLI cookbook: changing the API version

This topic describes how to change the API version.

### Procedure

1. Log in to the Delphix Engine as the admin user.

```
delphix> su - admin@DOMAIN
```

2. Run the version command.

```
delphix> version
1.10.3 # This lists the current API verison.
delphix> version <version you want to set to>
delphix> version
1.8.2 # Displays the new version that you had set above.
```

## CLI cookbook: hosts and environments

This section contains the following topics:

- [CLI cookbook: adding a UNIX host](#)
- [CLI cookbook: adding a SQL Server source environment](#)
- [CLI cookbook: setting multiple addresses for a target host](#)
- [CLI cookbook: how to change environment user](#)
- [CLI cookbook: how to create or edit a privilege elevation profile and profile scripts](#)
- [CLI cookbooks: enabling and configuring environment permissions](#)

## CLI cookbook: adding a UNIX host

This topic describes the process of adding a UNIX host using the 3.0 command-line interface.

Within Delphix, there are both hosts and host environments. A host represents a remote system, but may or may not be a source or target for linking or provisioning. For example, in an Oracle RAC cluster, the cluster environment represents the location of the Oracle installation(s), and while there are hosts within that cluster they are not individually manageable as environments.

### Procedure

1. Create a new environment and set the parameter type to be a UNIX host.

```
delphix> environment create
delphix environment create *> set type=HostEnvironmentCreateParameters
delphix environment create *> set hostEnvironment.type=UnixHostEnvironment
delphix environment create *> set hostParameters.type=UnixHostCreateParameters
delphix environment create *> set
primaryUser.credential.type=PasswordCredential
delphix environment create *> get
  type: HostEnvironmentCreateParameters
  hostEnvironment:
    type: UnixHostEnvironment
    name: (unset)
    aseHostEnvironmentParameters: (unset)
    description: (unset)
    logCollectionEnabled: false
  hostParameters:
    type: UnixHostCreateParameters
    host:
      type: UnixHost
      address: (required)
      dspKeystoreAlias: (unset)
      dspKeystorePassword: (unset)
      dspKeystorePath: (unset)
      dspTruststorePassword: (unset)
      dspTruststorePath: (unset)
      javaHome: (unset)
      nfsAddressList: (unset)
      oracleJdbcKeystorePassword: (unset)
      privilegeElevationProfile: (unset)
      sshPort: 22
      sshVerificationStrategy: (unset)
      toolkitPath: (required)
  logCollectionEnabled: false
  primaryUser:
    type: EnvironmentUser
    name: (unset)
    credential:
      type: PasswordCredential
      password: (required)
  environment: (unset)
```

```
groupId: (unset)
userId: (unset)
```

2. Set the host address. The name of the environment is derived from the address used, though you can provide a more descriptive name if desired. The address can be DNS names, IP addresses, or a comma-separated list of the above.

```
delphix environment create *> set hostParameters.host.address=192.168.1.2
```

3. Set the toolkit path. This is where Delphix will store temporary binaries used while the host is configured as part of Delphix.

```
delphix environment create *> set hostParameters.host.toolkitPath=/work
```

4. Set the username and password to use when connecting over SSH. This user must have the privileges described in the Delphix Administration Guide. To configure an SSH user, change the credential type to `SystemKeyCredential`.

```
delphix environment create *> set primaryUser.name=oracle
delphix environment create *> set primaryUser.credential.password
Enter primaryUser.credential.password: *****)
```

5. Commit the result. The environment discovery process will execute as an asynchronous job. The default behavior is to wait for the result, so progress will be updated until the discovery process is complete or fails.

```
delphix environment create *> commit
UNIX_HOST_ENVIRONMENT-4
Dispatched job JOB-39
ENVIRONMENT_CREATE_AND_DISCOVER job started for "192.168.1.2".
ENVIRONMENT_CREATE_AND_DISCOVER job for "192.168.1.2" completed
successfully.
delphix>
```

## CLI cookbook: adding a SQL Server source environment

This topic describes how to add a SQL Server source environment using the command line interface.

Since SQL Server source environments do not have the Delphix Connector running on them, you must use a target environment as a proxy when adding source environments. Delphix uses the connector running on the proxy environment to run commands against the source environment. See [Overview of Requirements for SQL Server Environments](#) for more information.

### Procedure

Enter these commands through the command-line interface:

```
/environment; create;set type=HostEnvironmentCreateParameters; set
hostEnvironment.type=WindowsHostEnvironment;set hostEnvironment.name=<Source
environment name>;set hostEnvironment.proxy=<target host name>; set
hostParameters.type=WindowsHostCreateParameters;set
hostParameters.host.type=WindowsHost;set hostParameters.host.address="<Source host IP
address or hostname>"; set primaryUser.name="<domain\username>";set
primaryUser.credential.type>PasswordCredential;set
primaryUser.credential.password=<password>; commit;
```

### Example

The CLI commands for adding source host "mssql\_source\_1" using target host "mssql\_target\_1" as proxy and environment user "ad\delphix\_user" would be:

```
/environment; create;set type=HostEnvironmentCreateParameters; set
hostEnvironment.type=WindowsHostEnvironment;set hostEnvironment.name="mssql_source_1";
set hostEnvironment.proxy="mssql_target_1"; set
hostParameters.type=WindowsHostCreateParameters;set
hostParameters.host.type=WindowsHost;set hostParameters.host.address="mssql_source_1";
set primaryUser.name="ad\delphix_user";set
primaryUser.credential.type>PasswordCredential;set
primaryUser.credential.password="i_am_the_password"; commit;
```

## CLI cookbook: setting multiple addresses for a target host

This topic is an example of using arrays to configure a target host to support multiple IP addresses. The `nfsAddressList` property is an array of strings.

## Procedure

1. Select the host to update

```
delphix> hostdelphix host> select exampledelphix host "example"> update
```

2. Set the address:

```
Delphix host '192.168.121.141' update *> set nfsAddressList="192.168.1.23,192.168.2.44"
```

3. Get the current addresses, both as a string and as an array object.

```
delphix host "example" update *> get nfsAddressList 192.168.1.23,192.168.2.44 (*)
delphix host "example" update *> get nfsAddressList[0] 192.168.1.23 (*)
delphix host "example" update *> edit nfsAddressListdelphix host "example"
update addresses *> get 0: 192.168.1.23 (*) 1: 192.168.2.44 (*)
```

4. Commit the result:

```
delphix host "example" update addresses *> commitdelphix host "example">
```

## CLI cookbook: how to change environment user

1. ssh into your engine using Admin privileges

```
ssh admin@delphix
```

2. Go to Environment and find the Environment you would like to update

```
delphix > environmentdelphix environment > lsdelphix environment > select
test_env
```

3. Select Environment updating and Update

```
delphix environment "test_env" > updatedelphix environment "test_env" update *>
ls
```

4. Set `primaryUser` to new user you would like to use for the Environment (NOTE: new user should be added as an environment user before making as a primaryUser)

```
delphix environment "test_env update" *> set primaryUser=<new user>
```

5. Commit the operation.

```
delphix environment "test_env" update *> commit
```

## Example:

```
ssh admin@delphixdelphix > environmentdelphix environment > ls ObjectsNAME
DESCRIPTIONDemo ChildrenoracleuserOperationscreate delphix environment > select
Demodelphix environment "Demo" > updatedelphix environment "Demo" update *> ls
Properties type: UnixHostEnvironment name: Demo description:
primaryUser: delphix delphix environment "Demo" update *> set primaryUser=<new
user>delphix environment "Demo" update *> commit
```

## CLI cookbook: how to create or edit a privilege elevation profile and profile scripts

## Background:

If you are running a version prior to 6.0.0 please contact your Professional Services representative.

## Procedure for creating an elevation profile:

1. Log into the CLI using `delphix_admin` or a user with Admin privileges and got to 'Host'.

```
ssh admin@youengine  
youengine > host
```

2. Select `privilegeElevation` then `profile`.

```
youengine host > privilegeElevation  
youengine host privilegeElevation > profile
```

3. Set the name of the profile and the version of the profile.

```
youengine host privilegeElevation profile *> set name=<profilename>  
youengine host privilegeElevation profile *> set version=<profileversion>
```

4. Commit the profile to save it.

```
youengine host privilegeElevation profile *> commit
```

## Procedure for creating a profileScript

Please note that you will need to create the script yourself or with the help of the Professional Services team.

1. Log into the CLI using `delphix_admin` or a user with Admin privileges and got to 'Host'.

```
ssh delphix_admin@youengine  
youengine > host
```

2. Select `privilegeElevation` then `profileScript`.

```
youengine host > privilegeElevation  
youengine host privilegeElevation > profileScript
```

3. Create your script by setting, name, contents, and profile (this can be your previously created profile or the default sudo).

```
youengine host privilegeElevation profileScript > create  
youengine host privilegeElevation profileScript *> set name=<scriptname>  
youengine host privilegeElevation profileScript *> set contents=<your script>
```

```
youengine host privilegeElevation profileScript *> set profile=<yourprofile>
```

4. Commit to save.

```
youengine host privilegeElevation profileScript *> commit
```

## Privilege elevation profiles and Delphix replication

Because all Delphix Engines have a default Profile called sudo, which would normally exist on both source and target Delphix Engines, replication collisions which would normally prevent a successful failover are automatically resolved.

- Only Profiles which are actually assigned to a host are replicated. All currently unassigned profiles are ignored.
- Profile name collisions are resolved by the display names of duplicate Profiles being prefixed with a unique object identifier. This is described in more detail in the next section.
- A default Profile will not retain default status after replication failover. The Profile assigned as default on the replication target Delphix Engine will remain the default. Therefore, if the source Delphix Engine has a non-standard default Profile, it will need to be manually set as the new default on the replication target Delphix Engine after failover.

## Caveats

By design, the Delphix Engine allows the creation of Profiles with duplicate names. This is not a bug. It exists for several reasons:

- This allows replication failover to complete without duplicate Profile names triggering a collision.
- Makes versioning possible so that a profile with the same name can have multiple versions as iterations are made (some of which may not be production-ready).

However, this behavior has the consequence of changing the display name of Profiles. Once a duplicate name exists, a unique object identifier is prefixed to the name. Any references to such a profile (such as assigning to a host) must use the long format with the unique identifier. For example, standard Delphix Engine has the following Profile:

```
Delphix5031HWv8> host privilegeElevation profile ls
Objects
NAME          ISDEFAULT
sudo          true
Operations
create
```

If a new profile that is also called "sudo" is created, the display names automatically change as follows:

```
Objects
NAME          ISDEFAULT
`HOST_PRIVILEGE_ELEVATION_PROFILE-1/sudo  true
`HOST_PRIVILEGE_ELEVATION_PROFILE-5/sudo  false
Operations
create
```

## Known issues

- It is not possible to delete a Profile. Attempting to do so results in an API error. However, Profiles can be renamed to something meaningful like "unused\_1".
- Profiles created that contain single quotation marks can no longer be selected. They become orphaned Profiles.

- When pasting in script contents, the cursor does not correctly move to the end of the last line being pasted. Unless the cursor is moved to the end of the line before pressing ENTER, the script will not be complete.

Neither of the above issues has any operational impact.

## CLI cookbooks: enabling and configuring environment permissions

This topic describes how to enable the environment permissions feature to restrict what users can do with environments.

By default, all engine users can list all environments and hosts and see their details. Moreover, all users are able to link dSources from and provision VDBs to any environment without requiring any permissions on environments, as long as they have [appropriate permissions on the target group where the dsource or VDB will be located](#).

### Enabling environment and permissions

To restrict non-administrator users from seeing, linking from, and provisioning to any environment, Delphix administrators can enable environment authorizations.

```
delphix> authorization configurationdelphix authorization configuration >
lsProperties      type: AuthorizationConfig  environmentAndHostAuth: false
Operationsupdatedelphix authorization configuration> updatedelphix authorization
configuration update *> set environmentAndHostAuth=true
delphix authorization
configuration update *> commit
```

Similarly, to go back to the default state in which all users have permission to perform those operations, the Delphix administrator must set the `environmentAndHostAuth` property back to `false`.

### Granting and revoking permissions on environments and hosts

When environment permissions are enabled, only Delphix administrators can list environments and hosts, see their details, or link dSources from or provision VDBs to environments.

To authorize any other user to perform such an operation on an environment or host, a Delphix administrator must create an appropriate authorization.

```
delphix> authorization createdelphix authorization create *> set user=someuserdelphix
authorization create *> set role=PROVISIONERdelphix authorization create *> set
target=SourceEnvironment:/somehost.example.com
```

To revoke an authorization, a Delphix administrator must delete the corresponding authorization object.

```
delphix> authorizationdelphix> lsREFERENCE      USER      ROLE      TARGET
AUTHORIZATION-1  sysadmin  OWNER     sysadminAUTHORIZATION-2  admin      OWNER
adminAUTHORIZATION-3  admin      OWNER     domain0AUTHORIZATION-4  someuser   Data
SourceEnvironment:/somehost.example.com delphix authorization> select
`AUTHORIZATION-4delphix authorization '(USER-2, ROLE-2, UNIX_HOST_ENVIRONMENT-1)'>
deletedelphix authorization '(USER-2, ROLE-2, UNIX_HOST_ENVIRONMENT-1)' delete *>
commit
```

### Permissions on Environments and Hosts

<b>Role</b>	<b>Environment privileges</b>	<b>Host privileges</b>

## CLI cookbook: linking an Oracle staging push database

This topic describes how to link an Oracle Staging Push database using the Delphix Engine command-line interface.

### Prerequisites

You will need the following information:

- The name of the dSource you want to create.
- The group in which you want to create the dSource.
- The Database Name of the Source Database whose data will be populated on this staging database.
- The Repository and the Mount Base.

### Linking a CDB

#### Procedure

- Execute the *database link* command

```
delphix> database link  
delphix database link>
```

- The default *linkData.type* in the *LinkParameters* is set to *ASELinkData*, but you can confirm that by getting the input type. Set *linkData.type* to *OracleLinkFromStaging* for Oracle Staging Push database.

```

delphix database link *> get linkData.type
    ASELinkData
delphix database link *> set linkData.type=OracleLinkFromStaging
delphix database link *> get linkData.type
    OracleLinkFromStaging (*)
delphix database link *> ls
Properties
  type: LinkParameters
  name: (required)
  description: (unset)
  group: (required)
  linkData:
    type: OracleLinkFromStaging (*)
    allowAutoStagingRestartOnHostReboot: (required)
    containerType: (required)
    customEnvVars: (unset)
    databaseName: (required)
    externalFilePath: (unset)
    operations: (unset)
    sourcingPolicy: (unset)
    stagingSourceParameters: (required)
    syncParameters:
      type: OracleStagingPushSyncParameters
    syncStrategy: (required)
    uniqueName: (required)

```

Operations  
defaults

- Set the name for the CDB dSource and the group in which you want to create it.

```

delphix database link *> set name=exampleCDB1
delphix database link *> set group="<Group Name>"

```

- Set the container type to *ROOT\_CDB* for the container database.

```

delphix database link *> set linkData.containerType=ROOT_CDB

```

- Set the *databaseName*, *uniqueName*, and other *linkData* properties. The database name here should be the same as the database name of the Source Database whose data will be populated on this staging database.

```

delphix database link *> set linkData.databaseName="<database_name>"
delphix database link *> set linkData.uniqueName=CDB_1_UNQ_NAME
delphix database link *> set linkData.allowAutoStagingRestartOnHostReboot=true
delphix database link *> set linkData.syncStrategy.type=OracleStagingPushSyncStrategy

```

- Set staging source properties - *mountBase*, *instanceName*, and *repository* among others.

```

delphix database link *> edit linkData.stagingSourceParameters
delphix database link linkData.stagingSourceParameters *> ls

```

## Properties

```

type: OracleStagingSourceParameters (*)
configParams: (unset)
configTemplate: (unset)
environmentUser: (unset)
instanceName: (required)
mountBase: (required)
physicalStandby: (unset)
repository: (required)
delphix database link linkData.stagingSourceParameters *> set mountBase=/mnt/staging
delphix database link linkData.stagingSourceParameters *> set
instanceName=CDB_1_INSTANCE_NAME

```

If you are unsure of the available repositories, you can list available repositories:

```

delphix database link linkData.stagingSourceParameters *> /repository list
NAME                                VERSION    ENVIRONMENT
'/u01/app/oracle/product/18.0.0.0/dbhome_1'  18.0.0.0.0  env1
'/u01/app/oracle/product/19.8.0.0/dbhome_1'  19.8.0.0.0  env2
delphix database link linkData.stagingSourceParameters *> set repository='/u01/app/
oracle/product/19.8.0.0/dbhome_1'

```

- Commit the result.

```

delphix database link *> commit
`ORACLE_DB_CONTAINER-45
Dispatched job JOB-129
DB_LINK job started for "<Group Name>/exampleCDB1".
Creating new TimeFlow for dSource "exampleCDB1".
Generating required scripts needed for the staging database.
Mounting datasets on the staging host "<staging host>".
Starting staging database "<database_name>" for dSource "exampleCDB1" in NOMOUNT
mode.
DB_LINK job for "<Group Name>/exampleCDB1" completed successfully.
delphix>

```

## Linking a PDB

## Procedure

- Execute the *database link* command.

```

delphix> database link
delphix database link>

```

- Set *linkData.type* to *OraclePDBLinkFromStaging* for Oracle Staging Push pluggable database.

```

delphix database link *> set linkData.type=OraclePDBLinkFromStaging

```

- Set the name for the PDB dSource and the group in which you want to create it.

```
delphix database link *> set name=examplePDB1
delphix database link *> set group="<Group Name>"
```

- Set *linkData.cdbConfig* to the config of the linked staging push CDB dSource, where this PDB should be plugged into. For Oracle databases, configs are identified by the database's unique name. You can list available source configurations:

```
delphix database link *> /sourceconfig list
NAME                REPOSITORY                LINKINGENABLED
CDB_1_UNQ_NAME      '/opt/ora/dexample1'     true
CDB_2_UNQ_NAME      '/opt/ora/dexample2'     true
delphix database link *> set linkData.cdbConfig=CDB_1_UNQ_NAME
```

- Set *databaseName*, *syncStrategy.type* and other *linkData* properties. The database name here should be the same as the database name of the source PDB whose data will be populated on this staging PDB.

```
delphix database link *> set linkData.databaseName=CDOMLOS381EPDB1
delphix database link *> set linkData.syncStrategy.type=OracleStagingPushSyncStrategy
delphix database link *> set linkData.allowAutoStagingRestartOnHostReboot=true
```

- Commit the result.

```
delphix database link *> commit
examplePDB1
  Dispatched job JOB-136
  DB_LINK job started for "<Group Name>/examplePDB1".
  Creating new TimeFlow for dSource "examplePDB1".
  Generating required scripts needed for the staging database.
  Mounting datasets on the staging host "<staging_host>".
  DB_LINK job for "<Group Name>/examplePDB1" completed successfully.
```

## CLI cookbook: detaching and attaching a SQL server dSource

This topic describes how to detach and attach a SQL server dSource. When attaching a SQL Server dSource to a new data source, the new data source must be in the same database satisfying the following constraints:

- pptRepository needs to be set to the name of the SQL instance on the staging server. The unlink operation removes the database from the SQL instance on the staging server and unmounts the iscsi luns, reattaching the dSource via the CLI will remount the iscsi luns and puts the database back.

### Prerequisites

A dSource can only be attached to a new data source once it has been [unlinked](#).

### Procedure

1. Select dSource.

```
delphix> database "dexample"
```

2. Run the detachSource command, specifying the current active source. This step can be skipped if the dSource has already been detached. through the GUI.

```
delphix database "dexample"> detachSource
delphix database "dexample" detachSource *> set source=dexample
delphix database "dexample" detachSource *> commit
```

3. Run the attachSource command.

```
delphix database "dexample"> attachSource
```

4. Set the following for SQL Server: You can also type help pptRepository to see what is wanted You can also set pptRepository=<then press tab> to list all values.

```
delphix database "dexample" attachSource *> edit attachData
delphix database "dexample" attachSource attachData *> set type=MSSqlAttachData
delphix database "dexample" attachSource attachData *> set config=SQLSERVER/dexample
delphix database "dexample" attachSource attachData *> set sharedBackupLocations="<\\
\SERVER1\Backups>"
delphix database "dexample" attachSource attachData *> set pptRepository=SQL2008R2
delphix database "dexample" attachSource attachData *> set mssqlUser.type=MSSqlDomainUser
delphix database "dexample" attachSource attachData *> set mssqlUser.user=ad\dbuser
delphix database "dexample" attachSource attachData *> set mssqlUser.password=dbuserpwd
delphix database "dexample" attachSource attachData *> edit ingestionStrategy
delphix database "dexample" attachSource attachData ingestionStrategy *> set type=ExternalBackupIngestionStrategy
delphix database "dexample" attachSource attachData ingestionStrategy *> set validatedSyncMode=TRANSACTION_LOG
delphix database "dexample" attachSource attachData ingestionStrategy *> back
delphix database "dexample" attachSource attachData *> edit operations.preSync
delphix database "dexample" attachSource attachData operations.preSync *> back
```

```
database "dexample" attachSource attachData*> edit operations.postSyncdelphix  
database "dexample" attachSource attachData " operations.postSync *> back
```

5. Commit the operation.

```
delphix database "dexample" attachSource *> commit
```

## CLI cookbook: disabling LogSync for a dSource

This topic provides a simple example of how the nested state is represented and manipulated. The LogSync state is maintained in the sourcingPolicy property of dSources, itself an object with several different fields.

## Procedure

1. Select the dSource to be changed and run the `update` command.

```
delphix> database "example"  
delphix "example"> update
```

2. Get the current property using dot-delimited notation.

```
delphix "example" update *> get sourcingPolicy.logsyncEnabled  
true
```

3. The property could also be set using dot-delimited notation, but for illustrative purposes, we can also use the `edit` command and set it directly.

```
delphix "example" update *> edit sourcingPolicy  
delphix "example" update sourcingPolicy *> set logsyncEnabled=false
```

4. Commit the state, either from within the editing context or after running `back` to return to the parent context.

```
delphix "example" update sourcingPolicy *> commit  
delphix "example">
```

## CLI cookbook: enabling Oracle validated sync

## Prerequisite - designating a staging host

In order to validate an Oracle dSource snapshot for syncing, the Delphix Engine requires a host with an Oracle installation that is compatible with the dSource. This machine is known as the **staging** host. You must explicitly designate which machines you want the Delphix Engine to use as staging hosts. All machines that have been marked as staging sites are added to a pool. During validated sync, the Delphix Engine will select a compatible host from the pool, export the requisite archived redo logs and datafiles, and execute Oracle media recovery on the host. Follow these steps to designate a staging host.

1. Select the repository you want to designate as staging.

```
delphix>/repository/select '/u01/app/ora10205/product/10.2.0/db_1'
```

2. Execute the `update` command.

```
delphix repository "/u01/app/ora10205/product/10.2.0/db_1">update
```

3. Set staging to `true`.

```
delphix repository "/u01/app/ora10205/product/10.2.0/db_1" update *>set staging=true
```

4. `Commit` the operation to designate the repository as staging.

```
delphix repository "/u01/app/ora10205/product/10.2.0/db_1" update *> commit
```

To configure validated sync for multiple dSources with different Oracle versions, you must designate a compatible staging source for each. If multiple compatible staging sites exist, the Delphix Engine will select one at random.

The validated sync process will consume some resources on the staging host when snapshots are taken. Designating a performance-critical host as a staging host is not recommended.

## Procedure - Enabling validated sync

1. Select the dSource for which you want to enable validated sync.

```
delphix>/database/select redsox1
```

2. Execute the `update` command.

```
delphix database "redsox1">update
```

3. Set `preProvisioningEnabled` to `true`.

```
delphix database "redsox1" update *>set preProvisioningEnabled=true
```

4. **Commit** the operation to enable validated sync.

```
delphix database "redsox1" update *>commit
```

CLI cookbook: linking a SQL Server database loading from a specific full backup of the source database

This topic describes how to use the command-line interface to link a SQL Server database by loading from a specific full backup of the source database as indicated by the backup UUID.

#### Prerequisites

- You can get the backup UUID for the all backup files of a chosen database using the following query on the source database under the column **backup\_set\_uuid**

```
Use masterselect backupset.database_name,      backupset.type,
backupset.backup_set_id,      backupset.backup_set_uuid,
backupset.family_guid,      backupset.position,      backupset.first_lsn,
backupset.last_lsn,      backupset.database_backup_lsn,      backupset.name,
backupset.has_bulk_logged_data,      backupset.is_damaged,
backupset.begins_log_chain,      backupset.is_copy_only,
backupset.backup_finish_date,      backupset.database_version,
backupset.database_guid,mediafamily.logical_device_name,mediafamily.physical_de
vice_namefrom msdb.dbo.backupmediafamily mediafamily join msdb.dbo.backupset
backupseton mediafamily.media_set_id = backupset.media_set_id where
backupset.database_name = N'<Database Name>'order by
backupset.backup_finish_date desc
```

#### Procedure

Enter these commands through the Delphix Engine command-line interface:

```
/database; link;set type=LinkParameters;set name=<dSource name>;set group=<group
name>;set linkData.type=MSSqlLinkData;set
linkData.syncParameters.type=MSSqlExistingSpecificBackupSyncParameters;set
linkData.config=<source database>;set linkData.sharedBackupLocations="<source
database backup locations>";set linkData.pptRepository=<SQL instance on the staging
server>;set linkData.sourcingPolicy.type=SourcingPolicy;set
linkData.mssqlUser.type=MSSqlDomainUserset linkData.mssqlUser.user=ad\dbuserset
linkData.mssqlUser.password.password=dbuserpwdset
linkData.syncParameters.backupUUID=<backup UUID>;set
linkData.ingestionStrategy.type=<ingestion strategy type>;set
linkData.ingestionStrategy.validatedSyncMode=<validated sync mode type>; commit;
```

CLI cookbook: linking a SQL Server database loading from the last full backup of the source database

This topic describes how to use the command-line interface to link a SQL Server database by loading from the last full backup of the source database.

#### Procedure

Enter the following commands in the Delphix Engine command-line interface:

```
/database; link;set type=LinkParameters;set name=<dSource name>;set group=<group name>; set linkData.type=MSSqlLinkData;set linkData.syncParameters.type=MSSqlExistingMostRecentBackupSyncParametersset linkData.config=<source database>;set linkData.sharedBackupLocations="<source database backup locations>";set linkData.pptRepository=<SQL instance on the staging server>;set linkData.sourcingPolicy.type=SourcingPolicy;set linkData.mssqlUser.type=MSSqlDomainUserset linkData.mssqlUser.user=ad\dbuserset linkData.mssqlUser.password.password=dbuserpwdset linkData.ingestionStrategy.type=<ingestion strategy type>; commit;
```

## CLI cookbook: linking to a single instance Oracle database

This topic describes how to link to a single instance Oracle database using the Delphix Engine command-line interface.

### Prerequisites

You will need the following information:

- The name of the dSource you want to create.
- The group in which you want to create the dSource.
- The database unique name of the Oracle database you want to link to.
- The database username/password with sufficient privileges as described in the Delphix User Guide.
- The host environment user with sufficient privileges as described in the Delphix User Guide.

### Procedure

1. Execute the `database link` command.

```
delphix> database linkdelphix database link>
```

2. The default `linkData.type` in the `LinkParameters` is set to `ASELinkData`, but you can confirm that by getting the input type. Set `linkData.type` to `OracleLinkFromExternal` for Oracle database.

```
delphix database link *> get linkData.type ASELinkData
delphix database link *> set linkData.type=OracleLinkFromExternal
delphix database link *> get linkData.type
OracleLinkFromExternal (*)
delphix database link *> lsProperties
type: LinkParameters name: (required) description: (unset)
group: (required) linkData: type: OracleLinkFromExternal (*)
backupLevelEnabled: (unset) bandwidthLimit: (unset)
checkLogical: (unset) compressedLinkingEnabled: (unset) config: (required)
dbCredentials: type: PasswordCredential
password: (required) dbUser: (required) diagnoseNoLoggingFaults: (unset)
encryptedLinkingEnabled: (unset) environmentUser: (required)
externalFilePath: (unset) filesPerSet: (unset)
linkNow: (unset) nonSysCredentials: (unset) nonSysUser: (unset)
numberOfConnections: (unset) operations: (unset)
preProvisioningEnabled: (unset) rmanChannels: (unset)
sourcingPolicy: (unset) syncParameters: type: OracleSyncFromExternalParameters
doNotResume: (unset)
doubleSync: (unset) forceFullBackup: (unset)
skipSpaceCheck: (unset)
Operationsdefaults
```

3. Set the name for the dSource and the group in which you want to create it.

```
delphix database link *> set name=example1delphix database link *> set group=""
```

4. Set the source configuration.  
For Oracle databases, these are identified by the database unique name. If you are unsure of the set of available databases, you can list available source configurations.

```
delphix database link *> /sourceconfig listNAME      REPOSITORY
LINKINGENABLEDexample1 '/opt/ora/dexample1' trueexample2 '/opt/ora/
dexample1' true
delphix database link *> set linkData.config=example1
```

- Set the privileged database username/password.  
The password can be set like other properties, or the value can be omitted so that it can be manually inputted without exposing the password.

```
delphix database link *> set linkData.dbUser=delphix
delphix database link *> set
linkData.dbCredentials.passwordEnter dbCredentials.password: *****
```

- Set the privileged environment user.  
This user must be from the same environment as the associated source config set in step 4. You can list the set of available users through the `environment user list` command.

```
delphix database link *> /environment/user listNAME      oracle
delphix database link *> set linkData.environmentUser=oracle
```

- Adjust any other properties you may want, such as RMAN tunables, description, and whether to link now.  
The full set of options is described in the API documentation for the `OracleLinkFromExternal` type. If you set the `linkNow` property, then this operation will wait for the sync to complete, otherwise, you can perform the initial link by running the sync command at a later point

```
delphix database link *> set linkData.linkNow=true
```

- Commit the result.

```
delphix database link *> commit      `ORACLE_DB_CONTAINER-1`  Dispatched job
JOB-8      DB_LINK job started for "/example1".      Obtaining information from
source database "/example1".      Creating new TimeFlow for dSource "/example1".
The dSource "example1" was successfully linked from source database "/example1".
DB_LINK job for "/example1" completed successfully.
delphix>
```

## CLI cookbook: listing data source sizes

This topic describes a basic use of the CLI `list` command.

1. Switch to the source view and view the default list.

```
delphix> sourcedelphix source> list
NAME          CONTAINER  VIRTUAL  CONFIG example
example      false     examplevexample  vexample  true     vexample
```

2. List sources with their database size.

```
delphix> sourcedelphix source> select example
delphix source 'example'> get
runtime.databaseSize 2.80GB
```

## CLI cookbook: detaching and attaching an Oracle dSource

This topic describes how to attach a dSource to a different data source.

### Prerequisites

Before detaching an Oracle dSource, you must capture the following RMAN configuration:

- Level or SCN based backups
- Data load channel settings: number of channels and files per channel

The above RMAN configuration will be removed once the dSource is unlinked.

A dSource can only be attached to a new data source once it has been unlinked.

When attaching an Oracle dSource to a new data source, the new data source must be the same logical database satisfying the following constraints:

- Same dbid
- Same dbname
- Same creation time
- Same resetlogs SCN
- Same resetlogs time
- Same redo stream, where a log must exist with
  - Same sequence
  - Same thread
  - Same end SCN

For Oracle dSources, this procedure can be used to initially link from a standby server that is faster or less disruptive, unlink the dSource, and then attach it to the production server for subsequent incremental SnapSync operations. When you perform the attach operation, you will need the source config name of an unlinked database.

### Procedure

1. Select **dSource**.

```
delphix> database "dexample"
```

2. Run the **detachSource** **command**, specifying the currently active source. This step can be skipped if the dSource has already been detached through the GUI.

```
delphix database "dexample"> detachSource
delphix database "dexample"> detachSource *> set source=name-of-old-src-DB-server
delphix database "dexample"> detachSource *> commit
```

3. Run the **attachSource** **command**.

```
delphix database "dexample"> attachSource
```

4. Set the config to point to an unlinked source. The following is an example to attach to an Oracle data source: (Hint: use <TAB> to complete variable names and known values)

```

delphix database "dexample" attachSource *> set
attachData.type=OracleAttachDatadelphix database "dexample" attachSource *> set
attachData.config=name-of-dSource-as-shown-in-environmentdelphix database
"dexample" attachSource *> set attachData.environmentUser=myuserdelphix
database "dexample" attachSource *> set
attachData.oracleFallbackUser=orauserdelphix database "dexample" attachSource
*> edit attachData.oracleFallbackCredentialssdelphix database "dexample"
attachSource *> set set type>PasswordCredentialdelphix database "dexample"
attachSource *> set password=orauserpwd

```

The attachData.config listing can be observed in the administration GUI, under Manage (pull-down at the top) --> Environments --> choose your dSource --> select Databases (upper right).

The dSources shown on the new source DB server may acquire odd names eg. "P02:UNKNOWN:vwxyz". These are a side-effect of having multiple instances of the same container name (possible in DR); Delphix needs to disambiguate. If these do show, they indicate containers in the new environment. Successfully attaching to these and deleting the old environment will re-establish the original names.

5. 

```
delphix database "dexample" attachSource *> commit
```

## CLI cookbook: how to change database user password

1. ssh into your engine using Admin privileges.

```
ssh admin@delphixengine
```

2. Go to sourceconfig and find the Database that you need to update the password on.

```
delphix > sourceconfigdelphix sourceconfig > lsdelphix sourceconfig > select
<yourdatabase>
```

3. Update the password.

```
delphix sourceconfig "yourdatabase" > updatedelphix sourceconfig "yourdatabase"
update * > lsdelphix sourceconfig "yourdatabase" update * > set
credentials.password=<new password>
```

4. Commit the change.

```
delphix sourceconfig "database" update * > commit
```

## Example:

```
ssh admin@exampledelphix > sourceconfigdelphix sourceconfig > lsObjects NAME
REPOSITORY LINKINGENABLEDmeta1 '/u01/oracle/10.2.0.4/ee1' true
Operationscreate delphix sourceconfig > select metadelphix sourceconfig "meta1" >
ls Properties type: OracleSIConfig name: meta1 credentials: type:
PasswordCredential password: ***** databaseName: meta1 discovered:
true environmentUser: delphix instance: type: OracleInstance
instanceName: meta1 instanceNumber: 1 linkingEnabled: true
nonSysCredentials: (unset) nonSysUser: (unset) reference:
ORACLE_SINGLE_CONFIG-1 repository: '/u01/oracle/10.2.0.4/ee1' services:
0: type: OracleService discovered: true
jdbcConnectionString: jdbc:oracle:thin:@172.16.100.69:1525:meta1 1:
type: OracleService discovered: true jdbcConnectionString:

OperationsdeleteupdatevalidateCredentials delphix sourceconfig "meta1" >
updatedelphix sourceconfig "meta1" update * > set credentials.password=<new
password>delphix sourceconfig "meta1" update * > commit
```

## CLI cookbook: changing an SAP ASE dSource's staging database

## Prerequisites

In order to change an SAP ASE dSource's staging database, you need to know the name of the staging database and you need to disable the dSource.

## Procedure

1. To find the name of the staging database, hover the mouse over the "Staging Database" name on the dSource card in the GUI or issue the following command via the CLI (replacing "pubs2" with the name of the dSource and "delphix.acme.com" with the hostname of your Delphix Engine):

```
$ echo "/source; select pubs2; ls" | ssh admin@delphix.acme.com | grep
stagingSourcePassword:      stagingSource: dxpb91a7LJlwj933xvLPvd_pubs2
```

2. Disable the dSource by either toggling the "Enable/Disable" toggle in the Delphix Management application or by using the CLI:

```
$ ssh admin@delphix.acme.comdelphix> sourcedelphix source> select pubs2delphix
source 'pubs2'> disabledelphix source 'pubs2' disable *> set
type=SourceDisableParameters delphix source 'pubs2' disable *> commit
Dispatched job JOB-365 SOURCE_DISABLE job started for "pubs2".
SOURCE_DISABLE job for "pubs2" completed successfully.
```

3. Change the repository of the staging database to reside in the desired SAP ASE instance:

```
$ ssh admin@delphix.acme.comdelphix> sourceconfigdelphix sourceconfig> select
dxpb91a7LJlwj933xvLPvd_pubs2delphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2'>
updatedelphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2' update *>
lsProperties      type: ASESConfig      credentials: (unset)      databaseName:
dxpb91a7LJlwj933xvLPvd_pubs2      environmentUser: nstacksolasetest/sybase
linkingEnabled: false      repository: nstacksolasetest/SRC_157_4K      user:
(unset)delphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2' update *> set
environmentUser=nstacksolasetest/sybasedelphix sourceconfig
'dxpb91a7LJlwj933xvLPvd_pubs2' update *> set repository=nstacksolaseprod/
SRC_157_4K                                NSTACK_16K
RH68_ASE157_S1SQL2008R2                                SQL2012
nstacksolasetestg                                nstacksolasetest/
SRC_157_4Kdelphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2' update *> set
repository=nstacksolasetestgdelphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2'
update *> commit
```

**Hint:** Rapidly hit the "tab" key twice after typing "set repository=" to make the CLI present a list of available instances.

4. Enable the dSource:

```
delphix sourceconfig 'dxpb91a7LJlwj933xvLPvd_pubs2'> /sourcedelphix source>
select pubs2delphix source 'pubs2'> enabledelphix source 'pubs2' enable *> set
type=SourceEnableParameters delphix source 'pubs2' enable *> commit
```

```
Dispatched job JOB-367 SOURCE_ENABLE job started for "pubs2".  
SOURCE_ENABLE job for "pubs2" completed successfully.
```

## CLI cookbook: detaching and attaching a SAP ASE dSource

This CLI cookbook recipe describes how to Detach and Attach an SAP ASE dSource using the CLI.

### Prerequisites

A dSource can only be attached to a new data source once it has been unlinked.

When attaching an SAP ASE dSource to a new data source, the new data source must be the same logical database satisfying the following constraints:

- Same dbid
- Same dbname
- Same creation time

You must also make sure that you follow the normal prerequisites for an SAP ASE data source found in [SAP ASE Support and Requirements](#).

### Procedure

#### Detach a dSource

1. Login to the CLI as admin or a user with Admin privileges.
2. Select dSource.

```
delphix> database "dexample"
```

3. Run the `detachSourcecommand`, specifying the currently active source. Note: This step can be skipped if the dSource has already been detached through the GUI.

```
delphix database "dexample"> detachSource
delphix database "dexample" detachSource *> set source=dexample
delphix database "dexample" detachSource *> commit
```

#### Attach a dSource

1. Login to the CLI as admin or a user with Admin privileges.
2. Run the `attachSource` command.

```
delphix database "dexample"> attachSource
delphix database "dexample"
attachSource *> set attachData.config=dexample
delphix database "dexample"
attachSource *> set attachData.dbCredentials.password=sybase
delphix database "dexample"
attachSource *> set attachData.dbUser=sadelphix database "dexample"
attachSource *> set attachData.loadBackupPath=/tmp/backups
delphix database "dexample"
attachSource *> set
attachData.sourceHostUser="source_host_environment/sybase"
delphix database "dexample"
attachSource *> set
attachData.stagingHostUser="staging_host_environment/sybase"
delphix database "dexample"
attachSource *> set
attachData.stagingRepository="staging_ASE_servername_example"
delphix database "dexample"
attachSource *> lsProperties      type: ASEAttachSourceParameters
attachData:                      type: ASEAttachData          config: dexample (*)
```

```

dbCredentials:                type: PasswordCredential                password:
***** (*)                   dbUser: sa (*)                   dumpCredentials: (unset)
externalFilePath: (unset)     loadBackupPath: /tmp/backups (*)
loadLocation: (unset)         mountBase: (unset)                 operations: (unset)
sourceHostUser: source_ASE_servername_example/sybase (*)
stagingHostUser: staging_ASE_servername_example/sybase (*)
stagingPostScript: (unset)    stagingPreScript: (unset)
stagingRepository: staging_ASE_servername_example (*)
validatedSyncMode: ENABLED delphix database "dexample" attachSource *> commit
ASE_DB_CONTAINER-3          Dispatched job JOB-25          DB_ATTACH_SOURCE job started
for "Untitled/dexample".    DB_ATTACH_SOURCE job for "Untitled/dexample"
completed successfully.

```

 This command is only necessary if you are using a Remote Backup Server configuration from staging to the source, instead of an NFS mounted shared directory for backups and transaction log dumps:

```

delphix database "dexample" attachSource *> set
attachData.loadLocation.backupServerName=source_backupserver_name_example

```

## CLI cookbook: linking an SAP ASE database loading from the last full backup of the source database

This topic describes how to use the command-line interface to link an SAP ASE database by loading from the most recent full backup of the source database.

## Procedure

Enter the following commands in the Delphix Engine command-line interface:

```
ssh delphix_admin@delphixPassword: delphix> /database linkdelphix database link *>
set linkData.type=ASELinkDatadelphix database link *> set name=db2delphix database
link *> set group="ASE dSource"delphix database link *> set
linkData.config=db2delphix database link *> set linkData.dbUser=sadelphix database
link *> set linkData.dbCredentials.password=sybasedelphix database link *> set
linkData.loadBackupPath=/mnt/dumpdelphix database link *> set linkData.mountBase=/
mnt/provision/vdb_or_staging_database_namelphix database link *> set
linkData.sourceHostUser=nstackrh69/sybasedelphix database link *> set
linkData.stagingHostUser=nealorarh75/sybasedelphix database link *> set
linkData.stagingRepository=ASE157SP138delphix database link *> set
linkData.sourcingPolicy.logsyncEnabled=truedelphix database link *> set
linkData.sourcingPolicy.type=SourcingPolicydelphix database link *> unset
linkData.syncParametersdelphix database link *> edit linkData.syncParametersdelphix
database link linkData.syncParameters *> backdelphix database link *> lsProperties
type: LinkParameters      name: db2 (*)      description: (unset)      group: ASE dSource
(*)      linkData:          type: ASELinkData      config: db2 (*)
dbCredentials:            type: PasswordCredential      password: ***** (*)
dbUser: sa (*)            dumpCredentials: (unset)            dumpHistoryFileEnabled: false
externalFilePath: (unset)      loadBackupPath: /mnt/dump (*)      loadLocation:
(unset)      mountBase: /mnt/provision/vdb_or_staging_database_name (*)
operations: (unset)            sourceHostUser: nstackrh69/sybase (*)
sourcingPolicy:            type: SourcingPolicy (*)            logsyncEnabled: true
(*)      stagingHostUser: nealorarh75/sybase (*)            stagingOperations: (unset)
stagingPostScript: (unset)      stagingPreScript: (unset)            stagingRepository:

(*)      validatedSyncMode: ENABLED0operationsdefaultsdelphix database link *>
commit `ASE_DB_CONTAINER-209 Dispatched job JOB-3704 DB_LINK job started for
"ASE dSource/db2". DB_LINK job for "ASE dSource/db2" completed successfully.
```

 mountBase option

The **mountBase** parameter is an option that was added in Delphix 5.2 and higher. By default, Delphix mounts the staging database under the Delphix toolkit directory. If a directory is specified for this parameter, the staging database's NFS devices will be mounted under this directory rather than under the toolkit directory. This can be especially helpful when the dSource is linked with LogSync enabled. SAP ASE has a limit of 127 characters for the fully qualified path to the transaction logs specified in the "LOAD TRANSACTION" statement. When LogSync is enabled, Delphix keeps a copy of the transaction logs on the engine under the dSources "archive" folder. The default naming convention for the folders under the toolkit can easily cause the 127 character limit to be exceeded so it is highly recommended to use this parameter when enabling LogSync. The mountBase is limited to 87 characters ( the device names Delphix generates are 32 characters and the subdirectory containing the archive files is about 8 characters long). This leaves approximately 40 characters for the name of the transaction logs themselves. The mountBase

parameter must be unique for each VDB or staging database. The path can reside under a common parent directory for example, /mnt/provision but you must specify a unique child directory under the parent for each VDB or staging database using this optional parameter.xs

## CLI cookbook: VDBs

This section covers the following topics:

- [CLI cookbook: attaching or detaching a PDB](#)
- [CLI cookbook: attaching, detaching, or linking a CDB](#)
- [CLI cookbook: changing SGA parameter](#)
- [CLI cookbook: changing the SID of Oracle RAC VDBs](#)

- [CLI cookbook: migrating an Oracle RAC virtual PDB and a virtual CDB](#)
- [CLI cookbook: locating and updating the value of tdeKeyIdentifier](#)

## CLI cookbook: attaching or detaching a PDB

## PDB CLI attach

1. Ensure the new source environment has been fully discovered by the Delphix Engine, including CDB discovery.
2. Login to the engine via SSH with a Delphix admin account.
3. Select the PDB dSource database to be attached.

```

dvde.dcenter database 'R268PDB1'> attachSource
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.type=OraclePDBAttachData
dvde.dcenter database 'R268PDB1' attachSource *> set attachData.config=R268PDB1
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.environmentUser=ora12201
dvde.dcenter database 'R268PDB1' attachSource *> set attachData.dbUser=delphix
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.dbCredentials.password
Enter attachData.dbCredentials.password: *****
dvde.dcenter database 'R268PDB1' attachSource *> commit
R268PDB1
Dispatched job JOB-46
DB_ATTACH_SOURCE job started for "Untitled/R268PDB1".
Obtaining information from source database "Untitled/R268PDB1".
The dSource "R268PDB1" was successfully linked from source database
"Untitled/R268PDB1".

```

4. Attach the PDB dSource to the correct source PDB in the new environment using the attachSource command; you will need to specify the environment user and login credentials for the PDBdSource.

```

dvde.dcenter database 'R268PDB1'> attachSource
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.type=OraclePDBAttachData
dvde.dcenter database 'R268PDB1' attachSource *> set attachData.config=R268PDB1
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.environmentUser=ora12201
dvde.dcenter database 'R268PDB1' attachSource *> set attachData.dbUser=delphix
dvde.dcenter database 'R268PDB1' attachSource *> set
attachData.dbCredentials.password
Enter attachData.dbCredentials.password: *****
dvde.dcenter database 'R268PDB1' attachSource *> commit
R268PDB1
Dispatched job JOB-46
DB_ATTACH_SOURCE job started for "Untitled/R268PDB1".
Obtaining information from source database "Untitled/R268PDB1".
The dSource "R268PDB1" was successfully linked from source database
"Untitled/R268PDB1".

```

## PDB CLI detach

1. Login to the engine via SSH with a Delphix admin account.

2. Select the PDB dSource database to be detached.

```
dvde.dcenter> database
dvde.dcenter database> select "R268PDB1"
dvde.dcenter database 'R268PDB1'>
```

3. Detach the PDB dSource using the detachSource command:

```
dvde.dcenter database 'R268PDB1'> detachSource
dvde.dcenter database 'R268PDB1' detachSource *> set source=R268PDB1
dvde.dcenter database 'R268PDB1' detachSource *> commit
  Dispatched job JOB-45
  DB_DETACH_SOURCE job started for "Untitled/R268PDB1".
  DB_DETACH_SOURCE job for "Untitled/R268PDB1" completed successfully.
```

## CLI cookbook: attaching, detaching, or linking a CDB

This topic describes how to attach, detach, or link a CDB using the command-line interface.

A CDB is not automatically detached when you detach the last PDB of the CDB. The CDB still remains in an inactive state which in turn prevents you from removing the environment. Therefore, you must detach the CDB in order to remove the environment.

 You can perform detach or attach operations only via Command-Line Interface (CLI).

### CDB CLI detach

Perform the following steps to detach a CDB.

 You can detach a CDB only when there are no PDBs linked and the CDB does not have any vPDBs.

1. Login to the engine via SSH with a Delphix admin account.

```
$ ssh admin@YOUR_ENGINE
```

2. Select the CDB dSource database to be detached.

```
dvde.dcenter> cd databasedvde.dcenter database> select CDOMLOSR421Fdvde.dcenter
database 'CDOMLOSR421F'>
```

3. Detach the CDB dSource using the detachSource command.

```
dvde.dcenter database 'CDOMLOSR421F'> detachSourcedvde.dcenter database
'CDOMLOSR421F' detachSource *> set source=CDOMLOSR421Fdvde.dcenter database
'CDOMLOSR421F' detachSource *> commit    Dispatched job JOB-45
DB_DETACH_SOURCE job started for "Untitled/CDOMLOSR421F".    DB_DETACH_SOURCE
job for "Untitled/CDOMLOSR421F" completed successfully.
```

You must attach the CDB back before performing the following operations: linking a new PDB, attaching a PDB, provisioning a vPDB, or attaching a converted PDB. Failure to do this will either result in an error due to duplicated object or will create a second CDB that will duplicate the space used for the CDB.

### CDB CLI link

You can not perform an attach operation for PDBs that have already been detached from the primary CDB and are required to be attached to a standby CDB if the standby CDB is not already linked or attached. You must link the CDB manually before performing the PDB attach operation.

Perform the following steps to link a CDB.

1. Login to the engine via SSH with a Delphix admin account.

```
$ ssh admin@YOUR_ENGINE
```

2. Select the CDB dSource database to be linked.

```
dvde.dcenter> cd databasedvde.dcenter database> linkdvde.dcenter database link
*>
```

3. Link the CDB dSource using the link command.

```
dvde.dcenter database link *> set name=mycldbvde.dcenter database link *> set
group=Untitleddvde.dcenter database link *> edit linkDatadvde.dcenter database
link linkData *> set type=OracleLinkFromExternaldvde.dcenter database link
linkData *> set syncStrategy.config=CDOMSHSR6706dvde.dcenter database link
linkData *> set environmentUser=oracledvde.dcenter database link linkData *>
set linkNow=truevde.dcenter database link linkData *> commit
`ORACLE_DB_CONTAINER-23    Dispatched job JOB-171    DB_LINK job started for
"Untitled/mycldb".    Obtaining information from source database "Untitled/
mycldb".    Creating new TimeFlow for dSource "Untitled/mycldb".    Request to
SnapSync container database "Untitled/mycldb" after attaching it will be
ignored.    Action: Direct SnapSync of container database is not allowed.
Container                database SnapSync will be taken when SnapSync of
corresponding            pluggable database is taken.    The dSource"mycldb" as
successfully linked from source database "Untitled/mycldb".    DB_LINK job for
"Untitled/mycldb" completed successfully.
```

## CDB CLI Attach

Perform the following steps to attach a CDB.

1. Ensure the new source environment has been fully discovered by the Delphix Engine.
2. Login to the engine via SSH with a Delphix admin account.

```
$ ssh admin@YOUR_ENGINE
```

3. Select the CDB dSource database to be attached.

```
dvde.dcenter> cd databasedvde.dcenter database> select CDOMLOSR421Fdvde.dcenter
database 'CDOMLOSR421F'>
```

4. Attach the CDB dSource to the correct source CDB in the new environment using the attachSource command.

 When attaching a CDB linkNow=true command is ignored, then the CDBs can not be snapshotted directly. CDB snapshots will be taken when PDB requires a snapshot of the CDB.

```
dvde.dcenter database 'CDOMLOSR421F'> attachSourcedvde.dcenter database
'CDOMLOSR421F' attachSource *> edit attachDatadvde.dcenter database 'CDOMLOSR421F'
attachSource attachData *> set type=OracleAttachDatadvde.dcenter database
'CDOMLOSR421F' attachSource attachData *> set config=CDOMLOSR421Fdvde.dcenter
database 'CDOMLOSR421F' attachSource attachData *> set
environmentUser=oracledvde.dcenter database 'CDOMLOSR421F' attachSource *> commit
CDOMLOSR421F    Dispatched job JOB-46    DB_ATTACH_SOURCE job started for "Untitled/
```

```
CDOMLOSR421F". Starting validation of attach parameters for database
"CDOMLOSR421F". Obtaining information from source database "Untitled/CDOMLOSR421F".
The dSource "CDOMLOSR421F" was successfully linked from source database
"Untitled/CDOMLOSR421F".
```

## CLI cookbook: changing SGA parameter

Below outlines the procedure to change SGA parameter setting on a provisioned VDB.

### Procedure

1. Log into the Delphix Management application as `admin` or a user with Admin privileges.
2. Go to `source` and then `select` the name of the VDB that you would like to change the parameters of.
3. You are then going to `update` and edit the `configParams`.
4. Next, you are going to set `sga_target=` correct value.
5. `Commit` the operation so that it saves.

### Example

```
ssh admin@enginedelphix > sourcedelphix source > select "vdb_example"delphix source  
"vdb_example" > updatedelphix source "vdb_example" *> edit configParamsdelphix source  
"vdb_example" *> set sga_target=new valuedelphix source "vdb_example" *> commit
```

 Modifying configuration parameters for a vPDB is not supported, so this workflow will not succeed for a vPDB.

## CLI cookbook: changing the SID of Oracle RAC VDBs

This topic describes how to change the SID of instances in an Oracle RAC VDB.

This example demonstrates how to switch the instance name and number between two different hosts, from

```
SQL> select * FROM V$ACTIVE_INSTANCES;INST_NUMBER INST_NAME-----
-----
1 cnrac3:VchiBEB1
2 cnrac4:VchiBEB2
```

to

```
SQL> select * FROM V$ACTIVE_INSTANCES;INST_NUMBER INST_NAME-----
-----
1 cnrac4:VchiBEB1
2 cnrac3:VchiBEB2
```

## Procedure

1. Stop the VDB through the GUI and login to the Delphix CLI.
2. Select the sourceconfig of the RAC VDB whose instances you would like to rename.

```
kfc-manual.dcenter> sourceconfigkfc-manual.dcenter sourceconfig> select
Vchicago_BEB
```

3. Use the update command to change the properties of the sourceconfig.

```
kfc-manual.dcenter sourceconfig "Vchicago_BEB"> update
```

4. Type 'ls' to view the complete list of properties associated with the VDB's sourceconfig. For configurations with larger numbers of RAC instances, the listing may not show the individual instances but will instead display [...]. In order to see the instance configuration, type 'edit instances'.

```
kfc-manual.dcenter sourceconfig "Vchicago_BEB" update *> lsProperties type:
OracleRACConfig credentials: type: PasswordCredential
password: ***** environmentUser: ora1024 instances: 0:
type: OracleRACInstance instanceName: VchiBEB1
instanceNumber: 1 node: cnrac4 1: type:
OracleRACInstance instanceName: VchiBEB2 instanceNumber:
2 node: cnrac3 linkingEnabled: true nonSysCredentials: (unset)
nonSysUser: (unset) repository: '/u01/app/ora1024/product/10.2.0/db_1'
services: [ ... ] user: delphix
```

5. Use the Set command to change the values for instanceName and instanceNumber for each instance.

```
kfc-manual.dcenter sourceconfig "Vchicago_BEB" update *> set instances.0.instan
ceName=VchiBEB2kfc-manual.dcenter sourceconfig "Vchicago_BEB" update *> set
instances.0.instanceNumber=2kfc-manual.dcenter sourceconfig "Vchicago_BEB"
```

```
update *> set instances.1.instanceName=VchiBEB1kfc-manual.dcenter sourceconfig  
"Vchicago_BEB" update *> set instances.1.instanceNumber=1
```

6. Finally, commit the changes.

```
kfc-manual.dcenter sourceconfig "Vchicago_BEB" update *> commit;
```

7. Restart the VDB through the GUI for the changes to take effect on the VDB.

CLI cookbook: toggle new DBID generation upon refresh options for Oracle VDBs

This topic describes how to toggle **Generate new DBID upon refresh** option for Oracle VDBs.

#### Procedure

1. Login to the Delphix CLI.
2. Go to source.

```
delphix> source
```

3. Select the VDB that you need to update

```
delphix> source
```

4. Toggle new DBID value. The new DBID value can be true or false. If the `newDBID` parameter is set to false then the new DBID generation will stop.

```
delphix source VDBOMSRE71EE4_QGE> updatedelphix source VDBOMSRE71EE4_QGE> set  
newDBID=<new value>
```

5. Finally, commit the changes to save the changes.

```
delphix source VDBOMSRE71EE4_QGE> commit
```

6. Refresh the VDB through CLI to generate a new DBID if the `newDBID` parameter was set to true. If the `newDBID` parameter was set to false, the Delphix engine will use the same DBID as the parent.

```
delphix> /databasedelphix database> select 'VDBO_QGE' delphix database  
'VDBO_QGE'> refreshdelphix database 'VDBO_QGE' refresh> commit
```

## CLI cookbook: creating a policy

This will outline how to create a policy in the CLI, please note that you can also do this in the GUI.

## Procedure

1. ssh into your Delphix Engine using admin credentials.

```
ssh admin@delphixenginedelphix > ls
```

2. Go to `policies` and `createAndApply` (please note that you cannot just create a policy, you must `createAndApply`, in the GUI you have the option to just create) and set your policy parameter.

```
delphix > policydelphix policy > createAndApplydelphix policy createAndApply *>
set policy.type=< choose from QuotaPolicy, RefreshPolicy, RetentionPolicy,
SnapshotPolicy or SyncPolicy)delphix policy createAndApply *> set policy.name=<
name your policy>delphix policy createAndApply *> set
policy.customized=truedelphix policy createAndApply *> set policy.delphix
policy createAndApply *> set policy.provisionSource=(LATEST_SNAPSHOT or
LATEST_TIME_FLOW_LOG)
```

**i Info:**

If doing a `RefreshPolicy`, `SyncPolicy` or `SnapshotPolicy` you are also going to need to add the following:

```
delphix policy createAndApply *> edit policy.scheduleListdelphix policy
createAndApply policy.scheduleList * > adddelphix policy createAndApply
policy.scheduleList * > set cronString=delphix policy createAndApply
policy.scheduleList * > set cutoffTime=delphix policy createAndApply
policy.scheduleList * > back
```

3. Set your target parameters which are going to be a container, group etc.

```
delphix policy createAndApply *> set target=
```

4. Verify and `commit`.

```
delphix policy createAndApply *> lsdelphix policy createAndApply *> commit
```

## CLI cookbook: creating a VDB config template

This topic will address how to create a VDB Config Template in the CLI; this functionality is also available in the GUI.

## Procedure

1. ssh into your Delphix Engine using admin credentials.

```
ssh admin@<yourdelphixengine>
```

2. Go to `database` and then `template` and then `create`.

```
delphix > database templatedelphix database template > createdelphix database
template create *> set name=<set the name of database template>delphix database
template create *> set parameters.<set parameters you want>delphix database
template create *> set sourceType=<set the source>
```

3. Verify information and commit.

```
delphix database template create *> lsdelphix database template create *>
commit
```

## Example for Oracle:

```
ssh admin@testengine@testengine > database templattestengine
database template > createtestengine
database template create *> set name=oracletestengine
database template create *> set parameters.PGA_TARGET=100Mtestengine
database template create *> set parameters.MEMORY_TARGET=100Mtestengine
database template create *> set sourceType=OracleVirtualSourcetestengine
database template create *> lsProperties
  type: DatabaseTemplate
  name: oracle (*)
  description: (unset)
  parameters:
    MEMORY_TARGET: 100M (*)
    PGA_TARGET: 100M (*)
  sourceType: OracleVirtualSource (*)testengine
database template create *> commit
```

## Example for SQL Server:

```
ssh admin@testengine testengine > database template
testengine database template > create
testengine database template create *> set name=mssqlTemplate
testengine database template create *> set parameters.READ_COMMITTED_SNAPSHOT=ON
testengine database template create *> set sourceType=MSSqlVirtualSource
testengine database template create *> ls
Properties  type: DatabaseTemplate  name: mssqlTemplate (*)      description: (unset)
```

```
parameters:  
  READ_COMMITTED_SNAPSHOT: ON (*)  
  sourceType: MSSqlVirtualSource (*)  
testengine database template create *> commit
```

## CLI cookbook: determining the snapshot used to provision a VDB

## Procedure:

The parent snapshot can be determined using the CLI as follows:

1. Log into the server as a Delphix administrator:

```
ssh admin@<server_ip>
```

2. Select the VDB.

```
delphix> databasedelphix database> lsObjectsNAME          PARENTCONTAINER
DESCRIPTIONdSource1      - dSource2      - VDB1          dSource1      -VDB2
dSource2      -VDB3          dSource1      -delphix database> select VDB1
```

3. List the VDB parameters, and make a note of the currentTimeflow value.

```
delphix database "VDB1"> lsProperties      type: OracleDatabaseContainer      name:
VDB1      currentTimeflow: VDB1/default      description: (unset)
diagnoseNoLoggingFaults: true      endianness: BIG_ENDIAN      group: <New Group>
masked: false      os: HP-UX      parentContainer: dSource1      performanceMode:
false      processor: ia64      reference: ORACLE_DB_CONTAINER-10      runtime:
type: OracleDBContainerRuntime      logSyncActive: true      sourcingPolicy:
type: OracleSourcingPolicy      encryptedLinkingEnabled: false
logsyncEnabled: true      logsyncInterval: 300      logsyncMode:
ARCHIVE_ONLY_MODE      version:
```

4. Select the Timeflow listed for the VDB.

```
delphix database "VDB1"> /timeflowdelphix timeflow> select VDB1/defaultList the
timeflow parameters. The Snapshot used to provision the VDB is listed as
parentSnapshotdelphix timeflow "VDB1/default"> lsProperties
```

5. List the Timeflow parameters. The Snapshot used to provision the VDB is listed as parentSnapshot.

```
delphix timeflow "VDB1/default"> lsPropertiestype: OracleTimeflow      name:
VDB1/default      container: VDB1      parentPoint:      type:
OracleTimeflowPoint      location: 141285148      timeflow: dSource1/
default      parentSnapshot: @2013-02-14T15:07:28.491Z      reference:
ORACLE_TIMEFLOW-92572
```

## CLI cookbook: how to refresh a VDB from a specific snapshot

These steps will allow you to refresh a VDB from any specific snapshot, not just the most recent one.

1. Identify the VDB and snapshot that you want to use.

```
ssh admin@<yourengine>delphix > database lsdelphix database > /snapshotdelphix
snapshot > list database=<SOURCEOFSSNAPSHOT>
```

2. Go to the `database` and `refresh`.

```
delphix > /databasedelphix database > refresh
```

3. Now set what type of refresh you are going to do.

```
delphix database 'VDB' refresh *> set
timeflowPointParameters.type=TimeflowPointSnapshot
```

4. Set the snapshot

```
delphix database 'VDB' refresh *> set timeflowPointParameters.snapshot=@XXXX-
XX-XX:XX:XX.XXXZ
```

5. Commit the action.

```
delphix database 'VDB' refresh *> commit
```

**i** You can use `tab` to complete most actions in the CLI in addition to listing the possibilities that are available when setting parameters.

## CLI cookbook: Oracle VDB migration

This topic describes moving a VDB from one environment or installation to another.

VDBs can be moved (or migrated) between hosts by changing the source repository associated with the VDB source config.

### Restrictions

The following restrictions apply when migrating a VDB between repositories:

- When migrating a RAC VDB, the host of each `OracleRACInstance` must be updated as well.
- The mount point of the VDB source cannot be changed.
- The `database_unique_name` and `db_name` cannot be changed.
- The new environment and repository must be a compatible target environment.

### Procedure

1. Select the source associated with the VDB. By default, sources are named the same as the VDB.

```
delphix> source "vexample"
```

2. Disable the source by running the `disable` command and committing the operation.

```
delphix source "vexample"> disabledelphix source "vexample" disable *> commit
Dispatched job JOB-171 SOURCE_DISABLE job started for "vexample".
Starting disable of virtual database. Unexporting storage. Virtual
database disable successful. SOURCE_DISABLE job for "vexample" completed
successfully. delphix source "vexample">
```

3. Select the source config associated with the source. By default this is also the same name as the VDB. Update the repository and repository user associated with the source config.

```
delphix source "vexample"> get config vexampledelphix source "vexample"> /
sourceconfig "vexample"delphix sourceconfig "vexample">
```

4. Update the repository and repository user associated with the source config.

**⚠ Warning:** You must use the Environment name of the Environment because the repository requires the environment name and Oracle home location. Enable the source.

```
delphix sourceconfig "vexample"> updatedelphix sourceconfig "vexample" update *> set
repository=192.168.100.247/'/opt/oracle/product/10.2.0.4/db_1'delphix sourceconfig
"vexample" update *> set environmentUser=192.168.100.247/ora1024delphix sourceconfig
"vexample" update *> commitdelphix sourceconfig "vexample">
```

5. Enable the source.

```
delphix sourceconfig "vexample"> /source "vexample" enable  
delphix source "vexample" enable *> commit Dispatched job JOB-18 SOURCE_ENABLE job started for  
"vexample". Enabling dataset "vexample". Exporting storage containers from the  
Delphix Engine. Mounting datasets. Mounting filesystems for the virtual  
database instance "1". Starting virtual database. Starting instance 1 on  
virtual database "vexample". Virtual database "vexample" was successfully started.  
Dataset "vexample" enabled. SOURCE_ENABLE job for "vexample" completed  
successfully.  
delphix sourceconfig "vexample">
```

## CLI cookbook: provisioning a SAP ASE VDB

This topic describes how to provision an SAP ASE VDB using the command line interface.

### Prerequisites

You will need the following information:

- The name of the VDB you want to create
- The group in which to create the VDB
- The SAP ASE database name for the VDB
- The source dSource or VDB from which you wish to provision
- The semanticLocation, LSN, or timestamp of the point you want to provision from (if not using the most recent). You can run these commands to get the list of snapshots or timeflow ranges:

```
snapshot list database=dexamlesnapshot list timeflow=dexamlesnapshot list
fromDate="2020-03-01T00:00:00.000Z" toDate="2020-03-04T11:31:27.883Z"
```

- The target host on which you want to create the VDB. You can list the hosts with the /host list command.
- The source repository (SAP ASE instance on the target host) in which to create the VDB. These can be listed with the /repository list command.

### Procedure

1. Execute the database provision command.

```
delphix> database provision
```

2. Set the type for the new VDB

```
delphix database provision *> set type=ASEProvisionParameters
```

3. Use defaults to fill in most of the information and then customize any additional information that you do not want defaulted, for what information has been filled in after defaults you can do an ls for all fields:

```
delphix database provision *> defaultsdelphix database provision *>
lsProperties:   type: TimeflowPointSemantic   container: (unset)   location:
LATEST_POINTdelphix database provision *> set container=<dexample>delphix
database provision *> commit
```

4. Set the name and group for the new VDB.

```
delphix database provision *> set container.name=<vexample>delphix database
provision *> set container.group="<New Group>"
```

5. Set the name of the new VDB.

```
delphix database provision *> set sourceConfig.databaseName=<vexample>
```

6. Set the target Dataset Home.

```
delphix database provision *> set sourceConfig.repository=<Dataset Home>delphix
database provision *> set sourceConfig.environmentUser=<Host environment name/
sybase>
```

7. Set the source container from which to provision.

```
delphix database provision *> set timeflowPointParameters.container=<dexample>
```

8. Set the desired value for truncateLogOnCheckpoint

```
delphix database provision *> set truncateLogOnCheckpoint=false
```

9. Commit the configuration and start the DB\_PROVISION job

```
delphix database provision *> commit
```

## CLI cookbook: provisioning a single instance non-multitenant Oracle VDB

This topic describes how to provision a single instance non-multitenant Oracle VDB using the Delphix Engine command-line interface.

### Prerequisites

You will need the following information:

- The name of the VDB you want to create
- The group in which to create the VDB
- The Oracle database name
- The Oracle database unique name
- The Oracle database instance number
- The Oracle database instance name
- The source dSource or VDB from which you wish to provision. This will be referenced as the "container" in the "defaults" command below.
- The semanticLocation, SCN, or timestamp of the point you want to provision from. You can run these commands to get the list of snapshots or Timeflow ranges:

```
snapshot list database=dexampletimeflow "dexample" timeflowRanges; commit
```

- The base mount point on the target server where VDB data should be mounted
- The source repository (oracle install) in which to create the VDB. These can be listed with the `repository list` command.
- If you are using a VDB template, the name of the template to use.

### Procedure

1. Execute the `database provision` command.

```
delphix> database provision
```

2. Execute the `defaults` command. Once you commit this command, it will return a partially constructed provision parameters object.

```
delphix database provision> defaults
```

3. Set the Timeflow point source Timeflow and location.

```
delphix database provision defaults *> set type=TimeflowPointSemanticdelphix
database provision defaults *> set container=dexampledelphix database provision
defaults *> set location=LATEST_SNAPSHOT
```

4. Commit the operation to populate the defaults, as provided by the browser interface. At this point, the operation can be committed, though you will likely need to change the defaults to match the information.

```
delphix database provision defaults *> commit
```

- Set the name and group for the new VDB

```
delphix database provision *> set container.name=vexampldelphix database
provision *> set container.group=""
```

- Set the base mount point.

```
delphix database provision *> set source.mountBase=/mnt
```

- Set the source config type to be a single instance non-multitenant Oracle, and set the database name and database unique name. When provisioning from a RAC or single instance non-multitenant oracle source, the default type will match that of the repository selected by the defaults operation.

```
delphix database provision *> set sourceConfig.type=OracleSIConfigdelphix
database provision *> set sourceConfig.databaseName=vexampldelphix database
provision *> set sourceConfig.uniqueName=vexample123
```

- Set the instance name and number.

```
delphix database provision *> edit sourceConfig.instancedelphix database
provision sourceConfig.instance *> set instanceNumber=1delphix database
provision sourceConfig.instance *> set instanceName=vexampldelphix database
provision sourceConfig.instance *> back
```

- Set the target repository.

```
delphix database provision *> set sourceConfig.repository='/env/opt/oracle'
```

- Configure the Oracle database parameters. If you are using manually specified parameters, you can set the contents of `source.configParams`. If you want to use a template, you can set `source.configTemplate`.
- (Optional) Configure customer environment variables.  
Setting Environment Pair Values

```
delphix database provision *> edit customEnvVarsdelphix database provision
source.customEnvVars *> adddelphix database provision source.customEnvVars 0 *>
set type=OracleCustomEnvVarSIPairdelphix database provision
source.customEnvVars 0 *> set varName=MYVAR1delphix database provision
source.customEnvVars 0 *> set varValue=Value1delphix database provision
source.customEnvVars 0 *> backdelphix database provision source.customEnvVars 1
*> set type=OracleCustomEnvVarSIPairdelphix database provision
source.customEnvVars 1 *> set varName=MYVAR2delphix database provision
source.customEnvVars 1 *> set varValue=Value2delphix database provision
source.customEnvVars 1 *> back
```

**1. Note:**

1. **OracleCustomEnvVarSIFile** file should be in the following format.

```
export VARNAME1=VARVALUE1export VARNAME2=VARVALUE2
```

2. When provisioning to a RAC target, use the type as **OracleCustomEnvVarRACPair** or **OracleCustomEnvVarRACFile**.

```
delphix database provision source.customEnvVars 0 *> set  
type=OracleCustomEnvVarRACPair  
delphix database provision  
source.customEnvVars 0 *> set clusterNode=targetnode1  
delphix database  
provision source.customEnvVars 0 *> set varName=MYVAR1  
delphix database  
provision source.customEnvVars 0 *> set varValue=Value1  
delphix database  
provision source.customEnvVars 0 *> back
```

12. Commit the result.

```
delphix database provision *> commit
```

## CLI cookbook: provisioning a SQL server VDB

This topic describes how to provision a SQL Server VDB using the command line interface.

### Prerequisites

You will need the following information:

- The name of the VDB you want to create
- The group in which to create the VDB
- The SQL Server database name for the VDB
- The source dSource or VDB from which you wish to provision
- The semanticLocation, LSN, or timestamp of the point you want to provision from. You can run these commands to get the list of snapshots or timeflow ranges:

```
snapshot list database=dexamplsnapshot list timeflow=dexamplsnapshot list
fromDate="2020-03-01T00:00:00.000Z" toDate="2020-03-04T11:31:27.883Z"
```

- The target host on which you want to create the VDB. You can list the hosts with the `/host list` command.
- The source repository (SQL Server instance on the target host) in which to create the VDB. These can be listed with the `/repository list` command.

### Procedure

1. Execute the `database provision` command.

```
delphix> database provision
```

2. Execute the `defaults` command.

```
delphix database provision> defaults
```

3. Set the timeflow point source timeflow and location.

```
delphix database provision defaults *> set type=TimeflowPointSemanticdelphix
database provision defaults *> set container=dexampldelphix database provision
defaults *> set location=LATEST_SNAPSHOT
```

4. Commit the operation to populate the defaults, as provided by the browser interface. At this point, the operation can be committed, though you will likely need to change the defaults to match the information.

```
delphix database provision defaults *> commit
```

5. Set the name and group for the new VDB.

```
delphix database provision *> set container.name=vexample  
delphix database provision *> set container.group=""
```

6. Set the database name for the VDB on the target SQL Server instance.

```
delphix database provision *> set sourceConfig.databaseName=vexample
```

7. Set the target repository

```
delphix database provision *> set sourceConfig.repository=targetEnv/  
SQLServer2008
```

8. Commit the result.

```
delphix database provision *> commit
```

## CLI cookbook: provisioning a VDB from a timeflow bookmark

This topic describes how to create a Timeflow bookmark and use it to provision a single instance Oracle VDB using the Delphix Engine command-line interface.

You can create Timeflow bookmarks to give a semantically meaningful name to a TimeFlow point (scn, location or timestamp within a Timeflow). You can then use the bookmarks you created to execute the following database operations:

- Provision
- Refresh
- Export
- Test file mappings
- VDB Rewind

### Prerequisites

You will need the following information:

- The name of the Timeflow bookmark you want to create
- The name of the VDB you want to create
- The group in which to create the VDB
- The Oracle database name
- The Oracle database unique name
- The Oracle database instance number
- The Oracle database instance name
- The source dSource or VDB from which you wish to provision
- The SCN, or timestamp of the point you want to provision from. You can run these commands to get the list of snapshots or Timeflow ranges:

```
snapshot list database=dexampletimeflow "dexample" timeflowRanges; commit
```

- The base mountpoint on the target server where VDB data should be mounted
- The source repository (oracle install) in which to create the VDB. These can be listed with the `repository list` command.

### Creating the TimeFlow bookmark

1. Execute the `timeflow bookmark create` command.

```
delphix> timeflow bookmark create
```

2. Set the timeflow point to be Oracle timeflow point.

```
delphix timeflow bookmark create *> set timeflowPoint.type=OracleTimeflowPoint
```

3. Set the timeflow point timeflow and location

```
delphix timeflow bookmark create *> set timeflowPoint.timeflow=dexample/
defaultdelphix timeflow bookmark create *> set timeflowPoint.location=194551945
5791
```

4. Set the name of the timeflow bookmark

```
delphix timeflow bookmark create *> set name=myTimeFlowBookmark
```

5. Commit the result

```
delphix timeflow bookmark create *> commit TIMEFLOW_BOOKMARK-1
```

6. Display the list of timeflow bookmarks

```
delphix> timeflow bookmark lsObjectsNAME TAG TIMEFLOW
myTimeFlowBookmark - dexample/defaultOperationscreate
```

#### Provisioning from a TimeFlow bookmark

1. Execute the `database provision` command.

```
delphix> database provision
```

2. Set `defaults` and provide container (VDB or dSource) that you will be provisioning from

```
delphix database provision > defaultsdelphix database provision defaults > set
container=<VDB or dSource>delphix database provision defaults > commit
```

3. Set the `timeflowPointParameters` type to be `TimeflowBookmark`.

```
delphix database provision *> set
timeflowPointParameters.type=TimeflowPointBookmark
```

4. Set the timeflow bookmark.

```
database provision *> set timeflowPointParameters.bookmark=myTimeFlowBookmark
```

5. Set the name and group for the new VDB.

```
delphix database provision *> set container.name=vexampledelphix database
provision *> set container.group="Untitled"
```

6. Set the base mountpoint

```
delphix database provision *> set source.mountBase=/mnt
```

7. Set the source config type to be single instance Oracle, and set the database name and database unique name.

```
delphix database provision *> set sourceConfig.type=OracleSIConfigdelphix  
database provision *> set sourceConfig.databaseName=vexampldelphix database  
provision *> set sourceConfig.uniqueName=vexample123
```

8. Set the instance name and number.

```
delphix database provision *> edit sourceConfig.instancedelphix database  
provision sourceConfig.instance *> set instanceNumber=1delphix database  
provision sourceConfig.instance *> set instanceName=vexampldelphix database  
provision sourceConfig.instance *> back
```

9. Set the target repository.

```
delphix database provision *> set sourceConfig.repository=env/'/opt/oracle'
```

10. Commit the result.

```
delphix database provision *> commit
```

## CLI cookbook: provisioning a virtual PDB to a new virtual CDB

This topic describes how to provision a virtual pluggable database (vPDB) to a virtual container database (vCDB) using the command-line interface.

**⚠** This process applies to Oracle container databases (CDBs) and the pluggable databases (PDBs) found within them that have been linked to Delphix as dSources. As container databases can only be found in Oracle 12.1.0.1 releases and above of Oracle this topic is relevant to only these releases.

### Prerequisites

The provisioning of virtual PDBs in Delphix is dependent on the following entities being in place prior to attempting the creation of this type of Delphix dataset.

- A source container database must be linked to the engine.
- The source container database must have pluggable databases within it linked as dSources to Delphix.
- A destination host with an Oracle home of the same release as the source database must be available and already discovered as an Environment in Delphix.

In the example CLI provision detailed below the following databases are in place:

- The source container database is called "CDOMLOSRTB"
- The pluggable database found in "CDOMLOSRTB" that has been linked as a dSource is called "CDOMLOSRTBPDB1"
- The destination virtual container database will be called "cdbvirt"
- Within the Delphix Engine CLI the name of the repository (target Oracle home) on the target system is '/u01/app/oracle/product/12.2.0.1/dbhome\_1'
- The destination virtual pluggable database will be called "PDBS3" and run from virtual container database "cdbvirt"
- Delphix creates a temporary container database on the target host which will be used to establish the virtualized copy of the dSource PDB "pdborcl". This temporary CDB will be created and running during the provisioning process, it will be destroyed at the end of the provision of the virtual PDB.

### Procedure

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
$ ssh admin@YOUR_ENGINE
```

2. Move to the database provisioning command line object.

```
delphix> database provision
```

3. Give the dataset a name.

```
delphix database provision *> set container.name=PDBS3
```

4. Place the new dataset in a Group that appears in the Delphix GUI, in this case, the Targets group.

```
delphix database provision *> set container.group=Targets
```

5. Set the type of provision to perform, for Oracle virtual database (VDB) - VDB/vPDBs, the type will be OracleVirtualPdbSource.

```
delphix database provision *> setsource.type=OracleVirtualPdbSource
```

6. Set the destination mount point which Delphix NFS mounts are to be linked to under the virtual PDB. This folder must exist at a file system level on the target host. Do not use single quotes around the mount path.

```
delphix database provision *> set source.mountBase="/mnt/provision"
```

7. Name the vPDB. This is what it will appear as in the destination container database.

```
delphix database provision *> set sourceConfig.databaseName=PDBS3
```

8. Supply the dSource PDBs details. In this example, the provision will use the latest point in time available to the dSource PDB as the point in time from which to provision the vPDB. Setting a different timeflowPointParameters.type would allow you to use points in time other than the latest snapshot or latest point in time if this is what you desire. Using other types is not covered in this example

```
delphix database provision *> set  
timeflowPointParameters.container=CDOMLOSRTBPDB1
```

9. Give the virtual CDB a name:

```
delphix database provision *> set virtualCdb.container.name=cdbvirt
```

10. Place the virtual CDB in a Group that appears in the Delphix GUI, in this case, the target group.

```
delphix database provision *> set virtualCdb.container.group=Targets
```

11. If automatically restarting the vPDB and vCDB is not required after a reboot of the target host, set this to option to false.

```
delphix database provision *> set  
virtualCdb.source.allowAutoVDBRestartOnHostReboot=false
```

12. Set the destination mount point which Delphix NFS mounts are to be linked to under the virtual CDB. This folder must exist at a file system level on the target host. Do not use single quotes around the mount path.

```
delphix database provision *> set virtualCdb.source.mountBase="/mnt/provision"
```

13. Set the vCDB configuration type to one of OracleRACConfig or OracleSIConfig. RAC configurations are not covered in this article:

```
delphix database provision *> set virtualCdb.sourceConfig.type=OracleSIConfig
```

14. Set the database name for the virtual CDB:

```
delphix database provision *> set virtualCdb.sourceConfig.databaseName=cdbvirt
```

15. Set the target system environment user that will be used to run the virtual CDB:

```
delphix database provision *> set
virtualCdb.sourceConfig.environmentUser=oracle
```

16. Set the instance name and number for the virtual CDB

```
delphix database provision *> set
virtualCdb.sourceConfig.instance.instanceName=cdbvirt
delphix database provision
*> set virtualCdb.sourceConfig.instance.instanceNumber=1
```

17. Set the repository (Oracle home) on the target system that will be used to run the virtual CDB. In this example the Oracle home is `/u01/app/oracle/product/12.2.0.1/dbhome_1`:

```
delphix database provision *> set virtualCdb.sourceConfig.repository='/u01/app/
oracle/product/12.2.0.1/dbhome_1'
```

18. Set the database unique name for the virtual CDB:

```
delphix database provision *> set virtualCdb.sourceConfig.uniqueName=cdbvirt
```

19. Set the following two parameters to true or false, depending on whether the vCDB and vPDB should be restarted automatically following a target host reboot:

```
delphix database provision *> set
source.allowAutoVDBRestartOnHostReboot=true
delphix database provision *> set
virtualCdb.source.allowAutoVDBRestartOnHostReboot=true
```

20. Check that all the settings you require are in place using the "ls" command

```
delphix database provision *> lsProperties      type:
OracleMultitenantProvisionParameters  container:      type:
OracleDatabaseContainer                name: PDBS3 (*)  description: (unset)

```

21. Initiate the provision by committing the operation in the CLI.

```

delphix database provision *> commit    PDBS3    Dispatched job JOB-24
DB_PROVISION job started for "Targets/PDBS3".    Starting provision of the
virtual database "PDBS3".    Preparing multitenant container database "cdbvirt".
    Creating new TimeFlow.    Generating recovery scripts.    Exporting
storage.    Mounting filesystems to recover pluggable database on instance "1".
Mounting read-only archive log filesystem for the virtual database instance "1".
    Backing up Oracle spfile.    Mounting virtual database instance.
Disabling flashback on Oracle database.    Renaming Oracle datafiles.
Mounting virtual database instance.    Recovering Oracle pluggable database.
Creating control file.    Creating Oracle online logs.    Processing startup
init file.    Configuring initialization and server parameter files.
Mounting virtual database instance.    Performing Oracle resetlogs.    Creating
tempfiles.    Renaming readonly datafiles.    Finalizing Oracle pluggable
database.    Registering listeners.    Unmounting read-only archive log
filesystem for the virtual database instance "1".    Unmounting filesystems
after recovering pluggable database on instance "1".    Plugging in Oracle
pluggable database.    Opening Oracle pluggable database.    Setting OMF
destination for Oracle pluggable database.    Creating tempfiles.    Online
readonly tablespaces.    Enabling Oracle instances.    Checking Oracle
pluggable database plugin violations.    DB_PROVISION job for "Targets/PDBS3"
completed successfully.

```

## CLI cookbook: provisioning a virtual PDB in a target CDB

This topic describes how to provision a virtual pluggable database (vPDB) using the command-line interface.

**⚠** This process applies to Oracle container databases (CDBs) and the pluggable databases (PDBs) found within them that have been linked to Delphix as dSources. As container databases can only be found in Oracle **12.1.0.1** releases and above of Oracle this topic is relevant to only these releases.

### Prerequisites

Provisioning of virtual PDB's in Delphix is dependent on the following entities being in place prior to attempting the creation of this type of Delphix dataset.

- A source container database must be linked to the engine.
- The source container database must have pluggable databases within it linked as dSources to Delphix.
- A destination container database of the same Oracle release as the source database must exist in the target host. If this container database is a physical database, then it must be linked to Delphix. If it's a virtual container database, then it must be of Oracle version 12.1.0.2 or later.

In the example CLI provision detailed below the following databases are in place:

- The source container database is called "cdb12"
- The destination container database is called "cdbstage"
- The pluggable database found in "cdb12" that has been linked as a dSource is called "pdborcl"
- The destination virtual pluggable database will be called "pds2" and run from container database "cdbstage"

Delphix creates a temporary container database on the target host which will be used to establish the virtualized copy of the dSource PDB "pdborcl". This temporary CDB will be created and running during the provisioning process, it will be destroyed at the end of the provision of the virtual PDB.

### Procedure

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
$ ssh admin@YOUR_ENGINE
```

2. Set the type of provision to perform, for Oracle virtual database (VDB) - VDB/vPDBs, the type will be OracleVirtualSource.

```
set source.type=OracleVirtualPdbSource
```

3. Set the destination target environment/host through setting the sourceConfig environment user to perform the provision. A destination container database must already be running on this target host.

```
delphix database provision *> set sourceConfig.environmentUser=OEL6SIN1/delphix
```

4. Set the destination mount point which Delphix NFS mounts are to be linked to under the virtual PDB. This folder must exist at a file system level on the target host. Do not use single quotes around the mount path.

```
delphix database provision *> set source.mountBase="/mnt/provision"
```

- Set the login details for the provision and Delphix OS user who is to perform the provision.

```
delphix database provision *> set username=delphixdelphix database provision *>
set credential.type=PasswordCredentialdelphix database provision *> set
credential.password=delphix
```

- Give the dataset a name.

```
delphix database provision *> set container.name=PDBS2
```

- Place the new dataset in a Group that appears in the Delphix GUI, in this case, the target group.

```
delphix database provision *> set container.group=Targets
```

- If automatically restarting the VDB is not required after a reboot of the VDB target host, set this to option to false. False is possibly a better option given the container database would need to be running prior to any attempt to pull up a vPDB.

```
delphix database provision *> set source.allowAutoVDBRestartOnHostReboot=false
```

- Supply the destination container database name. This will be where the vPDB will ultimately be placed and run from on the target host.

```
delphix database provision *> set sourceConfig.cdbConfig=cdbstage
```

- Name the vPDB. This is what it will appear as in the destination container database.

```
delphix database provision *> set sourceConfig.databaseName=pdb2
```

- Supply the dSource PDBs details. In this example, the provision will use the latest point in time available to the dSource PDB as the point in time from which to provision the vPDB. Setting a different timeflowPointParameters.type would allow you to use points in time other than the latest snapshot or latest point in time if this is what you desire. Using other types is not covered in this example.

```
delphix database provision *> set timeflowPointParameters.container=PDBORCL
```

- Check that all the settings you require are in place using the "ls" command.

```
delphix database provision *> lsProperties type: OracleProvisionParameters
container: type: OracleDatabaseContainer name: PDBS2 (*) description:
(unset) diagnoseNoLoggingFaults: true group: Targets (*)
performanceMode: DISABLED preProvisioningEnabled: false sourcingPolicy:
(unset) credential: type: PasswordCredential (*) password: ***** (*)
maskingJob: (unset) newDBID: true (*) openResetlogs: true physicalStandby:
false source: type: OracleVirtualSource (*) name: (unset)
allowAutoVDBRestartOnHostReboot: false (*) archiveLogMode: true config:
(unset) configParams: (unset) configTemplate: (unset) customEnvVars:
(unset) fileMappingRules: (unset) manualProvisioning: false
```

```
mountBase: /mnt/provision (*)   nodeListenerList: (unset)   operations:
(unset)   redoLogGroups: 3   redoLogSizeInMB: 0   sourceConfig:   type:
OraclePDBConfig   cdbConfig: cdbstage (*)   databaseName: pdba2 (*)
environmentUser: (unset)   linkingEnabled: true   repository: (unset)
services: (unset)   timeflowPointParameters:   type: TimeflowPointSemantic
container: PDBORCL (*)   location: LATEST_POINT   username: delphix (*)
Operationsdefaults
```

13. Initiate the provision by committing the operation in the CLI.

```
delphix database provision *> commit PDBS2 Dispatched job JOB-333
DB_PROVISION job started for "Targets/PDBS2". Starting provision of the
virtual database "pdbs2". Preparing multitenant container database "cdbstage".
Creating new TimeFlow. Generating recovery scripts. Exporting storage.
Mounting filesystems to recover pluggable database on instance "1". Mounting
read-only archive log filesystem for the virtual database instance "1".
Recovering Oracle pluggable database. Mounting filesystems for the virtual
database instance "1". Unmounting filesystems after recovering pluggable
database on instance "1". Cleaning up objects created by pluggable database
provisioning. Opening Oracle pluggable database. DB_PROVISION job for
"Targets/PDBS2" completed successfully.
```

CLI cookbook: refresh a VDB from a specific timepoint or latest

This topic describes the steps to Refresh a VDB from a specific Timepoint or from Latest.

You can refresh from any point on Timeflow using SCN, location, or timestamp.

Prerequisites

You will need the following information:

- The VDB name
- The TimeFlow location, SCN, or timestamp of the point you want to provision from.

The default domain user created on Delphix Engines is now **admin** instead of `delphix_admin`. When engines created before 5.3.1 are upgraded to 5.3.1 or later they will retain their old username 'delphix\_admin'. To avoid complications Delphix recommends creating users with an admin role and then Disabling `delphix_admin`.

Log in to CLI:

```
$ ssh admin@<delphixengine>
```

Determine the TimeFlow

Run:

```
> timeflow "<dSource>" timeflowRanges> commit> cd
```

Perform the Refresh from specific Timepoint

```
> database > select <VDB name> > refresh> set timeflowPointParameters.type= (one of
TimeflowPointBookmark, TimeflowPointBookmarkTag, TimeflowPointLocation,
TimeflowPointSemantic, TimeflowPointTimestamp as appropriate)> set
timeflowPointParameters.location= (the location, timestamp, or bookmark you wish to
refresh to)> set timeflowPointParameters.timeflow= (the timeflow associated with
location)> commit
```

Perform the Refresh from Latest

```
> database > select <yourdatabase> > refresh> set timeflowPointParameters.container=
(Parent of VDB)> commit
```

## CLI cookbook: repairing a timeflow

## Prerequisites

- Know the dSource and Group you need to repair from
- Make sure that your retention policy is set correctly so that the ingested logs are within the retention

## Procedure

1. Log into the Delphix Engine as an Admin user. Go to Timeflow and then list. Find the name of the Timeflow that needs to be repaired.

```
ssh admin@<yourengine>delphix > timeflowdelphix timeflow > ls
```

2. List the missing logs for the Timeflow. The maximum number of logs reported is controlled by the value of the pageSize argument; if there are a very large number of missing logs, you may need to increase this value. Note the start and end scn of the missing log.

```
delphix timeflow > cd oracle/logdelphix timeflow oracle log> list
timeflow=example missing=true pageSize=1000
```

**Note:** If the output from the above command does not list any logs as missing, but there are one or more sequences reported as missing by the **Delphix Admin** browser-based app, please contact Delphix Technical Support for assistance.

3. Stage the missing logs.
  - a. Verify that there is sufficient free space.
  - b. Copy or restore the missing archive logs into an alternative directory on a server the Delphix Engine can access via the network. All files and subdirectories in the configured directory are searched recursively, so staging the archive logs to a location with no other files or folders will ensure the process completes in a timely manner.
  - c. Verify that the user being specified in the next step has permission to read these archive log files in the directory. The user credentials are optional if the host and user credentials have already been added to the Delphix Engine.

```
delphix timeflow oracle log > fetchdelphix timeflow oracle log fetch *>
set type=TimeflowLogFetchParametersdelphix timeflow oracle log fetch *>
set timeflow=exampledelphix timeflow oracle log fetch *> set
directory=[directory where you restored the log file]delphix timeflow
oracle log fetch *> set endLocation=[end SCN of the sequence]delphix
timeflow oracle log fetch *> set startLocation=[start SCN of the
sequence]delphix timeflow oracle log fetch *> set host=[hostname or IP of
the host you restored the file to]delphix timeflow oracle log fetch *> set
username=[a user that can read the file]delphix timeflow oracle log fetch
*> edit credentialdelphix timeflow oracle log fetch *> set
type=PasswordCredentialdelphix timeflow oracle log fetch *> set
password=[password for this user]
```

4. Commit the changes.

```
delphix timeflow oracle log > fetchdelphix timeflow oracle log fetch *> set
type=TimeflowLogFetchParametersdelphix timeflow oracle log fetch *> set
timeflow=exampldelphix timeflow oracle log fetch *> set directory=[directory
where you restored the log file]delphix timeflow oracle log fetch *> set
endLocation=[end SCN of the sequence]delphix timeflow oracle log fetch *> set
startLocation=[start SCN of the sequence]delphix timeflow oracle log fetch *>
set host=[hostname or IP of the host you restored the file to]delphix timeflow
oracle log fetch *> set username=[a user that can read the file]delphix
timeflow oracle log fetch *> edit credentialdelphix timeflow oracle log fetch
*> set type=PasswordCredentialdelphix timeflow oracle log fetch *> set
password=[password for this user]
```

 Only do ONE repair job at a time.

 It is possible for there to be more than one Timeflow visible for a given container/source. If that is the case, you can verify the current TimeFlow being used with:

```
delphix > databasedelphix database > select 'example'delphix database "example"> ls
```

Look for the `currentTimeflow` value.

CLI cookbook: rolling back a VDB

The following sections provide examples of how to rollback or rewind your VDB.

- [Rolling back or rewinding to a snapshot from a VDB](#)
- [Rolling back or rewinding to a snapshot using timeflow](#)
- [Rolling back or rewinding to a timeflow bookmark](#)

## Rolling back or rewinding to a snapshot from a VDB

1. Log into the Delphix Engine.

```
ssh admin@delphix_engine
```

2. List Timeflows for the database that you want to rollback to.

```
de > ls
de > timeflow
de timeflow > ls
```

3. Switch to the VDB you want to rollback.

```
de timeflow > cd /database
de database > ls
de database > select "vdb_example"
```

4. Rollback VDB using the VDB rollback function (note this can also be done in the GUI).

```
de database 'vdb_example' > rollback
de database 'vdb_example' rollback *> set timeflowPointParameters.container=
de database 'vdb_example' rollback *> set timeflowPointParameters.location=
de database 'vdb_example' rollback *> commit
```

## Rolling back or rewinding to a snapshot using timeflow

1. Log into the Delphix Engine.

```
ssh admin@delphix_engine
```

2. List Timeflows for the database that you want to rollback to.

```
de > lsde > timeflowde timeflow > ls
```

3. Switch to the VDB you want to rollback.

```
de timeflow > cd /databasede database > lsde database > select "vdb_example"
```

4. Use the switchTimeflow operation.

```
de database 'vdb_example' > switchTimeflowde database 'vdb_example'  
switchTimeflow *> set timeflow=<different timeflow>de database 'vdb_example'  
switchTimeflow *> commit
```

## Rolling back or rewinding to a timeflow bookmark

Requirements: Know the Timeflow bookmark that you want to use.

1. Log into the Delphix Engine.

```
ssh admin@<yourengine>
```

2. Retrieve database and Timeflow information that you would like to rewind/rollback to.

```
delphix > lsdelphix database > select "dexample"delphix database "dexample" >  
get currentTimeflow
```

3. Rollback/Rewind VDB.

```
delphix database "dexample" > rollbackdelphix database "dexample" rollback *>  
lsdelphix database "dexample" rollback *> set  
timeflowPointParameters.type=TimeflowPointBookmarkdelphix database "dexample"  
rollback *> set timeflowPointParameters.bookmark="bookmark example"delphix  
database "dexample" rollback *> commit
```

## CLI cookbook: rolling forward a VDB

This topic describes how to roll forward a virtual database after it has been rewound, as described in [Provisioning and Managing Virtual Databases](#).

Once a VDB has rewound to a specific TimeFlow point, the snapshots of its previous states are still available in Delphix Engine storage and are accessed via the command-line interface to restore those previous states. This is referred to as "rolling forward" a VDB.

## Procedure

1. Use the `ls` command to find the VDB you want to roll forward. In this example, the TimeFlows and their associated containers are listed. The VDB called `PVDB` will be the one to roll forward.

```
delphix timeflow> lsObjectsNAME                               CONTAINER
PARENTPOINT.TIMEFLOW          PARENTPOINT.LOCATION
PARENTPOINT.TIMESTAMPhrprod/default             hrprod      -
-                               -erpprod/default             erpprod      -
-                               -'DB_PROVISION@2013-11-25T17:37:06' PVDB          erpprod/
default                        657925                       -'DB_ROLLBACK@2013-11-25T18:2
4:16' PVDB                    'DB_PROVISION@2013-11-25T17:37:06' 678552
```

2. Use the `Select` command to select the database.

```
delphix database> select PVDB
```

3. Use the `rollback` command to roll forward the VDB.

```
delphix database "PVDB"> rollback
```

4. Use the `ls` command to display options for selecting TimeFlow parameters.

```
delphix database "PVDB" rollback *> lsProperties    type:
OracleRollbackParameters  credential: (unset)    timeflowPointParameters:
type: TimeflowPointSemantic  container: (required)    location:
LATEST_POINT    username: (unset)
```

5. Because this VDB was rolled back, two TimeFlows now exist for it. To rollback the VDB and roll it forward, select the original TimeFlow, because the original snapshots are associated with that TimeFlow.

```
delphix database "PVDB" rollback *> set
timeflowPointParameters.type=TimeflowPointLocationdelphix database "PVDB"
rollback *> set timeflowPointParameters.timeflow='DB_PROVISION@2013-11-25T17:3
7:06'
```

6. Use the `ls` command to view the parameter options for the TimeFlow you selected.

```
delphix database "PVDB" rollback *> lsProperties      type:
OracleRollbackParameters  credential: (unset)  timeflowPointParameters:
type: TimeflowPointLocation (*)      location: LATEST_POINT      timeflow:
'DB_PROVISION@2013-11-25T17:37:06' (*)      username: (unset)
```

7. Set the TimeFlow location to rollback the VDB to a particular Oracle SCN.

```
delphix database "PVDB" rollback *> set timeflowPointParameters.location=678994
```

8. Use the `ls` command to review all the options you selected before executing the commit.

```
delphix database "PVDB" rollback *> ls Properties      type:
OracleRollbackParameters  credential: (unset)  timeflowPointParameters:
type: TimeflowPointLocation (*)      location: 678994 (*)      timeflow:
'DB_PROVISION@2013-11-25T17:37:06' (*)      username: (unset)
```

9. `Commit` the changes.

```
delphix database "PVDB" rollback *> commit      Dispatched job JOB-369
DB_ROLLBACK job started for "ERP/PVDB".      Starting provision of the virtual
database "PVDB".      Creating new TimeFlow.      Generating recovery scripts.
Exporting storage.      Validating user environment settings on target host.
Mounting filesystems for the virtual database instance "1".      Mounting read-
only archive log filesystem for the virtual database instance "1".      Running
user-specified pre-provisioning script.      Recovering Oracle database.
Opening the virtual database "PVDB".      Opening Oracle database.      Oracle
recovery was successful.      Unmounting read-only archive log filesystem for the
virtual database instance "1".      Running user-specified post-provisioning
script.      The virtual database "PVDB" was successfully provisioned.
Starting snapshot of virtual database.      Processing database files of virtual
database.      Creating snapshot of virtual database.      Finalizing snapshot of
virtual database.      Virtual database "PVDB" snapshot successful.
DB_ROLLBACK job for "ERP/PVDB" completed successfully.
```

## CLI Cookbook: taking a snapshot

This article is to document how to take a Snapshot outside of the normal snapshot policy time using the CLI, you can also do this in the GUI using the camera icon. A Snapshot of a VDB is similar to bookmarking a point in time in the life of the VDB.

### Procedure:

1. ssh into the Delphix Engine using delphix\_admin credentials.
2. Go into databases and select the VDB or dSource you would like to take a Snapshot of .

```
ssh admin@denginedelphix > databasedelphix database > select vdb_test
```

3. You are now going to sync and commit the operation .

```
delphix database "vdb_test" > syncdelphix database "vdb_test" sync *> commit
```

4. You can verify the snapshot by going to snapshots and listing them

```
delphix database "vdb_test" > /snapshotdelphix snapshot > ls
```

## CLI cookbook: V2P: virtual to physical of a single instance non-multitenant Oracle database

This topic describes how to provision a physical single instance non-multitenant Oracle database using the Delphix Engine command-line interface.

### Prerequisites

You will need the following information:

- The instance name, instance number, and unique name of the Oracle database you wish to create
- The source dSource or VDB from which you wish to provision.
- The semanticLocation, SCN, or timestamp of the point you want to provision from. You can run these commands to get the list of snapshots or Timeflow ranges:

```
snapshot list database=dexampletimeflow "dexample" timeflowRanges; commit
```

- The layout of the filesystems on the target server where data should be exported.
- The source repository (oracle install) in which to create the VDB. These can be listed with the `repository list` command.

### Procedure

1. Execute the `database export` command.

```
delphix> database export
```

2. Set the Timeflow point type, source container, and location.

```
delphix database export *> set
timeflowPointParameters.type=TimeflowPointSemanticdelphix database export *>
set timeflowPointParameters.container=dexampledelphix database export *> set
timeflowPointParameters.location=LATEST_SNAPSHOT
```

3. Edit the sourceConfig configuration, specifying the parameters for the database created via V2P.

```
delphix database export *> edit sourceConfigdelphix database export
sourceConfig *> set type=OracleSIConfig delphix database export sourceConfig *>
edit instancedelphix database export sourceConfig instance *> lsdelphix
database export sourceConfig instance *> set instanceName=v2p_dbdelphix
database export sourceConfig instance *> set instanceNumber=1delphix database
export sourceConfig instance *> backdelphix database export sourceConfig *> set
repository=tserver/'/u01/app/ora11204/product/11.2.0/dbhome_1' delphix database
export sourceConfig *> set uniqueName=v2p_dbdelphix database export
sourceConfig *> set databaseName=v2p_dbdelphix database export sourceConfig *>
back
```

4. Set the destination locations.

```
delphix database export *> set filesystemLayout.targetDirectory=//u01/app/  
oracle/oradata/v2p_dbdelphix database export *> set  
filesystemLayout.archiveDirectory=archive delphix database export *> set  
filesystemLayout.dataDirectory=datafiles delphix database export *> set  
filesystemLayout.externalDirectory=external delphix database export *> set  
filesystemLayout.scriptDirectory=script delphix database export *> set  
filesystemLayout.tempDirectory=temp
```

5. Commit the configuration to execute the job.

```
delphix database export *> commit
```

CLI cookbook: V2P (virtual to physical) of a single instance Oracle database with datafiles on separate file systems  
This topic describes how to provision a physical single-instance Oracle database, with datafiles on separate file systems, using the Delphix Engine command-line interface.

By default, all of the customizable directories - `data`, `archive`, `temp`, `external`, and `script` will be placed under the `target` directory, with additional config files placed in the `target` directory itself. This provides no mechanism to place datafiles on separate file systems (i.e. `/data1` and `/data2`, which have the root directory as a common point). In order to allow this, the `useAbsolutePathForDataFiles` parameter must be specified.

### Prerequisites

You will need the following information:

- The instance name, instance number, and unique name of the Oracle database to create.
- The source dSource or VDB from which to provision.
- The semanticLocation, SCN, or timestamp of the point of which to provision from. Run these commands to get the list of snapshots or Timeflow ranges:

```
snapshot list database=dexampletimeflow "dexample" timeflowRanges; commit
```

- The layout of the filesystems on the target server where data should be exported.
- The source repository (oracle install) in which to create the VDB. These can be listed with the `repository list` command.

### Procedure

1. Execute the `database export` command.

```
delphix> database export
```

2. Set the Timeflow point type, source container, and location.

```
delphix database export *> set
timeflowPointParameters.type=TimeflowPointSemanticdelphix database export *>
set timeflowPointParameters.container=dexampledelphix database export *> set
timeflowPointParameters.location=LATEST_SNAPSHOT
```

3. Edit the sourceConfig configuration, specifying the parameters for the database created via V2P.

```
delphix database export *> edit sourceConfigdelphix database export
sourceConfig *> set type=OracleSIConfig delphix database export sourceConfig *>
edit instancedelphix database export sourceConfig instance *> lsdelphix
database export sourceConfig instance *> set instanceName=v2p_dbdelphix
database export sourceConfig instance *> set instanceNumber=1delphix database
export sourceConfig instance *> backdelphix database export sourceConfig *> set
repository=tserver/'/u01/app/ora11204/product/11.2.0/dbhome_1' delphix
database export sourceConfig *> set uniqueName=v2p_dbdelphix database export
```

```
sourceConfig *> set databaseName=v2p_dbdelphix database export sourceConfig *>
back
```

4. Set the destination locations, including `setAbsolutePathForDataFiles` to be true.

```
delphix database export *> set filesystemLayout.targetDirectory=/v2p_dbdelphix
database export *> set filesystemLayout.archiveDirectory=archive delphix
database export *> set filesystemLayout.dataDirectory=datafiles delphix
database export *> set filesystemLayout.externalDirectory=external delphix
database export *> set filesystemLayout.scriptDirectory=script delphix database
export *> set filesystemLayout.tempDirectory=tempdelphix database export *> set
filesystemLayout.useAbsolutePathForDataFiles=true
```

5. Specify the file mapping rules for each datafile and the location to which it should be exported. Each entry should be separated by a newline, and the entire mapping within double quotes.

```
set fileMappingRules="/u01/app/oracle/oradata/datafile1.dbf:/data1/
datafile1.dbf/u01/app/oracle/oradata/datafile2.dbf:/data1/datafile2.dbf/u01/
app/oracle/oradata/datafile3.dbf:/data2/datafile3.dbf/u01/app/oracle/oradata/
datafile4.dbf:/data2/datafile4.dbf"
```

6. Commit the configuration to execute the job.

```
delphix database export *> commit
```

## CLI cookbook: export a non-multitenant virtual Oracle database to ASM

This topic describes how to perform an export or an in-place conversion of a non-multitenant virtual database to a physical database using the Delphix Engine command-line interface. This procedure will work irrespective of the VDB being a single instance configuration or RAC.

### Prerequisites

You must have the following configuration before you start the export:

- Target ASM data diskgroup, or the diskgroup that will contain all the database files
- The VDB that needs to be exported to ASM.
- Optionally, the target ASM disk group for redo log files, database unique name for the resulting physical database and the number of RMAN channels.

 Ensure that a database instance with the same unique name as the VDB is not running on the target host before starting the below procedure, otherwise the export operation will fail.

### Procedure

1. Execute the `database export` command.

```
delphix> database export
```

2. Set the database export parameters type, transfer strategy type, storage strategy type, default target data diskgroup, and virtual source.

```
delphix database export *> set type=OracleDBExportParameters
delphix database export *> set storageStrategy.type=OracleExportASMStorageStrategy
delphix database export *> set
  storageStrategy.asmlayout.defaultDataDiskgroup=+DATA
delphix database export *> set transferStrategy.type=OracleExportDBInPlaceTransferStrategy
delphix database export *> set transferStrategy.virtualSource=v2p_db
```

 The above values are just examples. Replace the default data diskgroup and virtual source name to match your needs.

3. Optionally set the following parameters:
  - a. Target ASM disk group for redo log files.
  - b. Database unique name for the resulting physical database.
    - i. If no database unique name is specified, the default is the unique name of the VDB.
    - ii. If a database unique name is specified, as noted in step 2 of this procedure, you need to ensure that a database instance with the same database unique name as the VDB is not running on the target host.
  - c. Number of RMAN channels. Default value for the RMAN channels is 8.

```
delphix database export *> set
storageStrategy.asmlayout.redoDiskgroup=+REDO
delphix database export *> set transferStrategy.dbUniqueName=v2asm_db
delphix database export *> set transferStrategy.rmanChannels=10
```

**i** The above values are just examples. Replace the redo diskgroup, database unique name and number of RMAN channels to match your needs.

4. Commit the configuration to execute the job.

```
delphix database export *> commit
```

The export operation takes a snapshot of the VDB before proceeding with the export. After a successful export operation, the original VDB will be left in a DISABLED state. If the VDB needs to be re-enabled, the VDB needs to be migrated to a different host. Ensure there is no instance running with the same name as the VDB on the target host. Subsequently, you must rewind the VDB to the latest snapshot, after which the VDB will be back up and running. Since the export operation takes a snapshot before the actual export, the rewind can be performed to the point just before the export started.

Refer to the [“Export an Oracle VDB or a vPDB to a Physical ASM or Exadata Database”](#) page for additional considerations after a successful export.

## CLI cookbook: export a multitenant virtual pluggable Oracle database to ASM

This topic describes how to perform an export or an in-place conversion of a multitenant virtual pluggable database (vPDB) to a multitenant physical Oracle pluggable database (PDB) using the Delphix Engine Command-line Interface (CLI). This procedure will work irrespective of the vPDB being a single instance configuration or RAC.

### Prerequisites

You must have the following configuration before you start the export:

- Target ASM data diskgroup, or the diskgroup that will contain all the database files
- The vPDB that needs to be exported to ASM.
- Optionally, the pluggable database name for the resulting physical pluggable database and the number of RMAN channels.

**⚠** If the vPDB is being renamed during the export, confirm there is no other PDB with the same name in the target CDB before starting the below procedure. If a PDB with the same name exists in the target CDB, the export operation will fail before starting the actual movement of datafiles.

### Procedure

1. Execute the `database export` command.

```
delphix> database export
```

2. Set the database export parameters type, transfer strategy type, storage strategy type, default target data diskgroup, and virtual source.

```
delphix database export *> set type=OraclePDBExportParameters
delphix database export *> set
storageStrategy.type=OracleExportASMStorageStrategy
delphix database export *> set
storageStrategy.asmLayout.defaultDataDiskgroup=+DATA
delphix database export *> set
transferStrategy.type=OracleExportPDBInPlaceTransferStrategy
delphix database export *> set transferStrategy.virtualSource=v2p_pdb
```

**i** The above values are just examples. Replace the default data diskgroup and virtual source name to match your needs.

3. Optionally set the following parameters:
  - a. pluggable database name for the resulting physical pluggable database.
    - i. If a pluggable database name is specified, the target CDB should not have a PDB with the same name, otherwise the export will fail.
    - ii. If no pluggable database name is specified, the default is the current name of the pluggable database.
  - b. Number of RMAN channels. Default value for the RMAN channels is 8.

```
delphix database export *> set transferStrategy.pdbName=v2asm_pdb  
delphix database export *> set transferStrategy.rmanChannels=10
```

**i** The above values are just examples. Replace the redo diskgroup, database unique name and number of RMAN channels to match your needs.

4. Commit the configuration to execute the job.

```
delphix database export *> commit
```

The export operation takes a snapshot of the vPDB before proceeding with the export. After a successful export operation, the original vPDB will be left in a DISABLED state. If the vPDB needs to be re-enabled, the vPDB needs to be migrated to a different host and/or CDB. Ensure there is no PDB with the same name as the vPDB on the target CDB. Subsequently, you must rewind the vPDB to the latest snapshot, after which the vPDB will be back up and running. Since the export operation takes a snapshot before the actual export, the rewind can be performed to the point just before export started.

Refer to the [“Export an Oracle VDB or a vPDB to a Physical ASM or Exadata Database”](#) page for additional considerations after a successful export.

## CLI Cookbook: V2P virtual to physical on SQL server

This topic describes how to export a physical single instance SQL Server database from a VDB using the Delphix Engine command-line interface.

### Prerequisites

You will need the following information:

- The VDB name which you wish to export.
- The database name of the SQL Server database you wish to create
- The layout of the filesystems on the target server where data should be exported.
- The target repository in which to create the physical database. Repositories can be listed with the `repository list` command.

### Procedure

1. Execute the command `database export` .

```
delphix> database export
```

2. Specify the set type=MSSqlExportParameters

```
delphix database export *> set type=MSSqlExportParameters
```

3. Set the VDB you wish to export

```
delphix database export *> edit timeflowPointParameters
delphix database export timeflowPointParameters *> set container=vdb
delphix database export timeflowPointParameters *> back
```

4. Edit the sourceConfig configuration, specifying the parameters for the database created via V2P.

```
delphix database export *> edit sourceConfig
delphix database export sourceConfig *> set type=MSSqlSIConfig
delphix database export sourceConfig *> set databaseName=v2p_db
delphix database export sourceConfig *> set repository=win2012/SQL2016
delphix database export sourceConfig *> back
```

5. Set the destination locations.

```
delphix database export *> edit filesystemLayout
delphix database export filesystemLayout *> set targetDirectory=C:\temp
delphix database export filesystemLayout *> set archiveDirectory=archive
delphix database export filesystemLayout *> set dataDirectory=datafiles
delphix database export filesystemLayout *> set externalDirectory=external
delphix database export filesystemLayout *> set scriptDirectory=script
delphix database export filesystemLayout *> set tempDirectory=temp
```

6. Commit the configuration to execute the job.

```
delphix database export *> commit
```

## CLI Cookbook: VDB status

It is possible to get a virtual database (VDB) status from the CLI.

1. Log into the CLI as any user that has privileges on the VDB.

```
ssh admin@yourengine
```

2. From source go to the VDB you want to get a status on.

```
delphix > sourcedelphix source > lsdelphix source > select <yourvdb>
```

3. Run the get runtime command to see all information or just get runtime.status for if the VDB is running.

```
delphix source 'vdb' > get runtime
```

or

```
delphix source 'vdb' > get runtime.status
```

4. If you would like to see more than one VDBs status you can also do the following:

```
delphix > sourcedelphix source > list display=name,runtime.status
```

CLI cookbook: provisioning a virtual PDB from a non-multitenant source database

Delphix supports provisioning a vPDB from a non-multitenant source database. This feature is only available through the API or command-line interface.

This topic describes how to provision a virtual pluggable database (vPDB) from a non-multitenant source database using the command-line interface.

**⚠ This feature has the following restrictions:**

Transparent Data Encryption (TDE) is not supported.

The provision point must correspond to a snapshot. Provisioning from a point in time between snapshots is not supported.

The target CDB must be a physical CDB. Virtual CDB targets are not supported.

### Prerequisites

Provisioning a vPDB from a non-multitenant source has the following environment requirements:

- Source host with a non-multitenant Oracle 11g or newer source database.
- VDB target host for provisioning a virtual non-multitenant VDB from the source database.
- CDB target host with a running Oracle target version CDB. The target CDB will be automatically linked if it is not already linked.

The target CDB can be a newer Oracle version than the source database (for example, the source is 12.2 and target is 19c). When an upgrade is also required, there are two options for upgrading the database:

- Upgrade Option 1: After provisioning the VDB. This option requires the ability to upgrade to the Oracle target version on the VDB target host.
- Upgrade Option 2: After plugging into the Linked CDB target database.

There are three scripts used during this procedure:

1. **Pre-snapshot Hook on VDB**: This hook will open the database in "read only" mode and issue a call to the `dbms_pdb.describe` procedure to generate an XML file describing the VDB.
2. **Post-snapshot Hook on VDB**: This hook will return the VDB to "read write" mode.
3. **Non-CDB to PDB Script**: This script will run as a hook present on the Linked CDB target host. This should call into the Oracle script `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` to convert the VDB into a PDB. This script should also upgrade the vPDB if doing Upgrade Option 2.

### Workflow

1. Link the non-multitenant Oracle 11g or newer source database as a dSource within Delphix.
2. Provision a non-multitenant Oracle VDB from the dSource onto the VDB target host. This will be referred to as the **Golden VDB**.
3. (If using Upgrade Option 1) Upgrade the **Golden VDB** to the Oracle target version: manually upgrade the database and point it to the new Oracle home. This step is only necessary if the source and target Oracle versions are not the same and the data files will not be upgraded when they are converted below.
4. Create a **Pre-snapshot hook** on the **Golden VDB** to open the database in read only mode and issue the `dbms_pdb.describe` procedure call to create an XML file called `delphix_plugin.xml`. The XML file will be used to plug the **Golden VDB** data files into the target CDB. The **Golden VDB** must be open read only during the subsequent snapshot so that the VDB data files do not require recovery when plugging them into the target CDB.
5. (Optional) Create a **Post-snapshot hook** on the **Golden VDB** to remove the database from read only mode. The **Golden VDB** can also remain read only.

6. Take a snapshot of the **Golden VDB**.
7. Create a **PDB conversion script** named `dx-post-plug-hook.sh` in the root of the Delphix toolkit directory of the Linked CDB target host. The name of the vPDB being provisioned/converted will be supplied by Delphix as the first parameter to the script when it invokes the script. The VDB data files will already be plugged into the Linked CDB target at the time the script is invoked. The script should do the following:
  - a. (If using Upgrade Option 2) **Upgrade** the vPDB data files prior to the conversion.
  - b. Call into `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` and perform any customizations for the multitenant conversion.
8. Select a **snapshot** (point-in-time not supported) on the **Golden VDB** that has the `delphix_plugin.xml` file and provision a virtual PDB to the Linked CDB target. Virtual CDB targets are not supported. Note: This step can be executed via the **API / CLI only**, and will not be allowed via the Delphix UI.

#### CLI procedure to provision a vPDB from a VDB

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
$ ssh admin@YOUR_ENGINE
```

2. Move to the database provisioning command line object.

```
delphix> database provision
```

3. Set the parameter type to `OracleMultitenantProvisionParameters`.

```
set type=OracleMultitenantProvisionParameters
```

4. Set the login details for the provision and Delphix OS user who is to perform the provision.

```
delphix database provision *> set username=delphixdelphix database provision *>
set credential.type>PasswordCredentialdelphix database provision *> set
credential.password=delphix
```

5. Give the dataset a name.

```
delphix database provision *> set container.name=vpdb
```

6. Place the new dataset in a Group that appears in the Delphix GUI, in this case, the Targets group.

```
delphix database provision *> set container.group=Targets
```

7. Set the destination mount point which Delphix NFS mounts are to be linked to under the virtual PDB. This folder must exist at a file system level on the Linked CDB target host. Do not use single quotes around the mount path.

```
delphix database provision *> set source.mountBase="/mnt/provision"
```

8. If automatically restarting the vPDB is not required after a reboot of the Linked CDB target host, set this to option to false. False is possibly a better option given the container database would need to be running prior to any attempt to pull up a vPDB.

```
delphix database provision *> set source.allowAutoVDBRestartOnHostReboot=false
```

9. Supply the destination container database name. The container database should already be discovered. This will be where the vPDB will ultimately be placed.

```
delphix database provision *> set sourceConfig.cdbConfig=CDBSTAGE
```

10. Name the vPDB. This is what it will appear as in the destination container database.

```
delphix database provision *> set sourceConfig.databaseName=vpdb
```

11. Supply the source **Golden VDB** details. In this example, the provision will use the latest snapshot available from the **Golden VDB** as the point in time from which to provision the vPDB. A specific snapshot can also be picked, but an arbitrary point in time is not supported.

```
delphix database provision *> set
timeflowPointParameters.type=TimeflowPointSemantic
delphix database provision *>
set timeflowPointParameters.container=gold_vdb
delphix database provision *> set
timeflowPointParameters.location=LATEST_SNAPSHOT
```

12. Check that all the settings you require are in place using the "ls" command.

```
delphix database provision *> lsProperties type:
OracleMultitenantProvisionParameters container: type:
OracleDatabaseContainer name: vpdb (*) description: (unset)
diagnoseNoLoggingFaults: true group: Targets (*) performanceMode:
DISABLED preProvisioningEnabled: false sourcingPolicy: (unset)
credential: type: PasswordCredential (*) password: ***** (*) masked:
(unset) maskingJob: (unset) source: type: OracleVirtualPdbSource (*)
name: (unset) allowAutoVDBRestartOnHostReboot: false (*) config: (unset)
customEnvVars: (unset) fileMappingRules: (unset) LogCollectionEnabled:
false mountBase: /mnt/provision (*) operations: (unset)
parentTdeKeystorePassword: (unset) parentTdeKeystorePath: (unset)
tdeExportedKeyFileSecret: (unset) sourceConfig: type: OraclePDBConfig
cdbConfig: CDBSTAGE (*) databaseName: vpdb (*) environmentUser: (unset)
linkingEnabled: true nonSysCredentials: (unset) nonSysUser: (unset)
repository: (unset) services: (unset) timeflowPointParameters: type:
TimeflowPointSemantic container: gold_vdb (*) location: LATEST_SNAPSHOT
(*) username: delphix (*) VirtualCdb: (unset) Operationsdefaults
```

13. Initiate the provision by committing the operation in the CLI.

```
delphix database provision *> commit vpdb Dispatched job JOB-333
DB_PROVISION job started for "Targets/vpdb". Starting provision of virtual PDB
database "vpdb" converted from a single tenant database. Preparing multitenant
```

container database "CDBSTAGE". Creating **new** TimeFlow. Generating recovery scripts. Exporting storage. Preparing XML manifest file prior to plugin. Plugging in Oracle pluggable database. Running user-defined post plug hook. Opening Oracle pluggable database. Setting OMF destination **for** Oracle pluggable database. Creating PDB tempfiles. Checking Oracle pluggable database plugin violations. DB\_PROVISION job **for** "Targets/vpdb" completed successfully.

**i** To refresh the data in the vPDB from production, first, refresh the Golden VDB from the dSource, then refresh the vPDB from the new snapshot in the Golden VDB.

- i** There are some workflow customizations required for RAC databases:
1. The PDB conversion script must be in the root of the Delphix toolkit directory for all the target CDB RAC instances.
  2. The **Golden VDB** Pre-Snapshot hook, as provided below, will not work in a clustered (RAC) environment with more than one active instance because it only shuts down the local instance. `dbms_pdb.describe` will not execute while an instance is open read-write. The workarounds are:
    - a. Provision the **Golden VDB** as single-instance, either by provisioning to a non-RAC target or by provisioning to a RAC target with only one active instance. The sample hook will work in this case.
    - b. Write a customized pre-snapshot hook that shuts down all instances, restarts only one instance in read-only mode, and runs `dbms_pdb.describe`.
    - c. Manually perform the actions of the hook: shutdown the **Golden VDB**, restart one of the instances in read-only mode and then run `dbms_pdb.describe`.

## Sample scripts

### Golden VDB pre-snapshot hook

Restarts the source VDB in read only mode and runs `dbms_pdb.describe` to generate an XML file describing the VDB. The XML file will be used to plug the VDB into the Linked CDB target. The target for the XML file must be `$DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/delphix_plugin.xml`.

```
#!/bin/shsqlplus "/ AS SYSDBA" <<-EOF whenever sqlerror exit 2; spool
$DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/presnapshot.out replace
shutdown immediate startup mount alter database open read only; exec
dbms_pdb.describe(pdb_descr_file=>'$DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/
datafile/delphix_plugin.xml'); exit;EOF
```

### Golden VDB post-snapshot hook

This is only necessary if the VDB should not be left in read-only mode after the snapshot.

```
#!/bin/shsqlplus "/ AS SYSDBA" <<-EOF whenever sqlerror exit 2; spool
$DELPHIX_MOUNT_PATH/$DELPHIX_DATABASE_UNIQUE_NAME/datafile/postsnapshot.out replace
shutdown immediate startup exit;EOF
```

#### PDB conversion script

The script should be named `dx-post-plug-hook.sh` and reside in the root of the Delphix toolkit directory of the Linked CDB target host. Delphix will supply the name of the PDB being provisioned/converted as the first parameter.

The VDB datafiles will have already been plugged into the target CDB at the time the script is invoked and the virtual PDB will be in the mounted (not open) state. The PDB conversion script should return with the virtual PDB in either the mounted or open (not restricted) state. Delphix does not enforce a time-out for the script.

```
#!/bin/shDELPHIX_PDB_NAME=$1SCRIPT_DIR="$( cd "$( dirname "$0" )" && pwd )"CONVERT_LO
GFILE=$SCRIPT_DIR/$DELPHIX_PDB_NAME-pdbconvert.logsqlplus "/ AS SYSDBA" <<-EOF
whenever sqlerror exit 2; spool $CONVERT_LOGFILE replace alter session set
container=$DELPHIX_PDB_NAME; @?/rdbms/admin/noncdb_to_pdb.sql exit;EOF
```

#### PDB upgrade script

The following script will upgrade the vPDB. Use a wrapper that runs both this script and the prior conversion script (or combine the two in a single script) if doing both an upgrade and a conversion.

```
#!/bin/shDELPHIX_PDB_NAME=$1SCRIPT_DIR="$( cd "$( dirname "$0" )" && pwd )"UPGRADE_LO
GFILE=$SCRIPT_DIR/$DELPHIX_PDB_NAME-dx-post-plug-
upgrade.logUPGRADE_LOGDIR=$SCRIPT_DIR/$DELPHIX_PDB_NAME-upgrademkdir
$UPGRADE_LOGDIRcd $ORACLE_HOME/rdbms/adminswitches="-c '$DELPHIX_PDB_NAME' -l
$UPGRADE_LOGDIR"$ORACLE_HOME/perl/bin/perl catctl.pl $switches catupgrd.sql &>>
$UPGRADE_LOGFILE
```

## CLI cookbook: migrating a virtual PDB in a virtual CDB

Delphix supports migrating from a vPDB in a virtual CDB, to another linked or virtual CDB.

This topic describes how to migrate a virtual pluggable database (vPDB) in a virtual CDB to another virtual CDB using the command-line interface.

### Pre-requisites

You should already set up and have Delphix discover a container database in the same environment as the vPDB currently is or from an environment to which the vPDB will be migrated to.

### Procedure

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
ssh admin@YOUR_ENGINE
```

2. Disable the vPDB.

```
delphix> /sourcedelphix source> select myPDBdelphix source 'myPDB'>
disabledelphix source 'myPDB' disable *> commit    Dispatched job JOB-35
SOURCE_DISABLE job started for "myPDB".    Disabling virtual database "myPDB".
Unexporting storage containers.    Virtual database "myPDB" disabled.
SOURCE_DISABLE job for "myPDB" completed successfully.delphix source 'myPDB'>
```

3. Change the environment user and repository ( ORACLE\_HOME ) for the vPDB to the appropriate user from the new host.

```
delphix> /sourceconfigdelphix sourceconfig> select myPDBdelphix sourceconfig
'myPDB'> updatedelphix sourceconfig 'myPDB' update *> set repository='/u01/app/
oracle/product/19.0.0.0/dbhome_1'delphix sourceconfig 'myPDB' update *> set
environmentUser='/oracle'delphix sourceconfig 'myPDB' update *> commit
Dispatched job JOB-38    SOURCE_CONFIG_UPDATE job started for "myPDB".
SOURCE_CONFIG_UPDATE job for "myPDB" completed successfully.
```

4. Change the environment user and repository ( ORACLE\_HOME ) for the vCDB to the appropriate user from the new host. This must match the settings in step 3.

```
delphix sourceconfig 'myPDB'> /sourceconfig/delphix sourceconfig> select
myCDBdelphix sourceconfig 'myCDB'> updatedelphix sourceconfig 'myCDB' update *>
set repository='/u01/app/oracle/product/19.0.0.0/dbhome_1'delphix sourceconfig
'myCDB' update *> set environmentUser='/oracle'delphix sourceconfig 'myCDB'
update *> commit    Dispatched job JOB-39    SOURCE_CONFIG_UPDATE job started
for "myCDB".    SOURCE_CONFIG_UPDATE job for "myCDB" completed successfully.
```

5. Enable the vPDB.

```
delphix sourceconfig 'myCDB'> /sourcedelphix source> select myPDBdelphix source
'myPDB'> enabledelphix source 'myPDB' enable *> commit    Dispatched job JOB-40
SOURCE_ENABLE job started for "myPDB".    Enabling dataset "myPDB".
```

```
Exporting storage containers from the Delphix Engine.    Mounting datasets.
Mounting filesystems for the virtual database instance "1".    Starting virtual
database.    Starting instance 1 on virtual database "myCDB".    Virtual
database "myCDB" was successfully started.    Starting virtual database.
Starting instance 1 on virtual database "myPDB".    Plugging in Oracle
pluggable database.    Opening Oracle pluggable database.    Setting OMF
destination for Oracle pluggable database.    Creating PDB tempfiles.
Checking Oracle pluggable database plugin violations.    Virtual database
"myPDB" was successfully started.    Dataset "myPDB" enabled.    SOURCE_ENABLE
job for "myPDB" completed successfully.
```

## CLI cookbook: migrating an Oracle RAC virtual PDB and a virtual CDB

Delphix supports migrating from a RAC vPDB in a virtual CDB, to another RAC linked CDB or virtual CDB. This feature is only available through the command-line interface.

**⚠** Attempts to perform this migration via GUI will fail with the following error:  
**Error**  
 The operation could not be completed because the virtual database “vPDB1” is disabled.  
**Error Code**  
 exception.db.genericvdb.disabled

This topic describes how to migrate a RAC virtual pluggable database (vPDB) in a virtual CDB to another RAC virtual CDB using the command-line interface.

### Pre-requisites

You should already set up and have Delphix discover a container database in the same environment as the vPDB currently is or from an environment to which the vPDB will be migrated to.

### Procedure

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
ssh admin@YOUR_ENGINE
```

2. Disable the vPDB.

```
delphix> /sourcedelphix source> select racPDBdelphix source 'racPDB'>
disabledelphix source 'racPDB' disable *> commit    Dispatched job JOB-74
SOURCE_DISABLE job started for "racPDB".    Disabling virtual database "racPDB".
    Unexporting storage containers.    Virtual database "racPDB" disabled.
SOURCE_DISABLE job for "racPDB" completed successfully.
```

3. Change the environment user and repository ( ORACLE\_HOME ) for the vPDB to the appropriate user from the new host.

```
delphix source 'racPDB'> /sourceconfig/delphix sourceconfig> select
racPDBdelphix sourceconfig 'racPDB'> updatedelphix sourceconfig 'racPDB' update
*> set repository='/u01/app/oracle/product/12.1.0.2/dbhome_1'delphix
sourceconfig 'racPDB' update *> set environmentUser=' /oracle'delphix
sourceconfig 'racPDB' update *> commit    Dispatched job JOB-76
SOURCE_CONFIG_UPDATE job started for "racPDB".    SOURCE_CONFIG_UPDATE job for
"racPDB" completed successfully.
```

4. Change the environment user and repository ( ORACLE\_HOME ) for the vCDB to the appropriate user from the new host. This must match the settings in step 3. The instance configuration must also be configured for the new hosts.

```
delphix sourceconfig 'racPDB'> /sourceconfig/delphix sourceconfig> select
racCDBdelphix sourceconfig 'racCDB'> updatedelphix sourceconfig 'racCDB' update
*> set repository='/u01/app/oracle/product/12.1.0.2/dbhome_1'delphix
```

```

sourceconfig 'racCDB' update *> set environmentUser='/oracle' delphix
sourceconfig 'racCDB' update *> edit instances delphix sourceconfig 'racCDB'
update instances *> lsProperties 0: type: OracleRACInstance
instanceName: racCDB1 instanceNumber: 1 node: mwtestx1 1:
type: OracleRACInstance instanceName: racCDB2 instanceNumber: 2
node: mwtestx2 Use the "add" command to add an element to this array. delphix
sourceconfig 'racCDB' update instances *> set 0.node=mwtestz1 delphix
sourceconfig 'racCDB' update instances *> set 1.node=mwtestz2 delphix
sourceconfig 'racCDB' update instances *> commit Dispatched job JOB-77
SOURCE_CONFIG_UPDATE job started for "racCDB". SOURCE_CONFIG_UPDATE job for
"racCDB" completed successfully.

```

#### 5. Enable the vPDB.

```

delphix sourceconfig 'racCDB'> /source delphix source> select racPDB delphix
source 'racPDB'> enable delphix source 'racPDB' enable *> commit Dispatched
job JOB-78 SOURCE_ENABLE job started for "racPDB". Enabling dataset
"racPDB". Exporting storage containers from the Delphix Engine. Mounting
datasets. Mounting filesystems for the virtual database instance "2".
Starting virtual database. Starting instance 2 on virtual database "racCDB".
Virtual database "racCDB" was successfully started. Starting virtual
database. Starting instance 2 on virtual database "racPDB". Plugging in
Oracle pluggable database. Opening Oracle pluggable database. Setting OMF
destination for Oracle pluggable database. Creating PDB tempfiles.
Checking Oracle pluggable database plugin violations. Virtual database
"racPDB" was successfully started. Mounting datasets. Mounting
filesystems for the virtual database instance "1". Starting virtual
database. Starting instance 1 on virtual database "racCDB". Virtual
database "racCDB" was successfully started. Starting virtual database.
Starting instance 1 on virtual database "racPDB". Opening Oracle database.
Checking Oracle pluggable database plugin violations. Virtual database
"racPDB" was successfully started. Dataset "racPDB" enabled.
SOURCE_ENABLE job for "racPDB" completed successfully.

```

## CLI cookbook: locating and updating the value of tdeKeyIdentifier

This topic describes how to manage the tdeKeyIdentifier field that is associated with the vPDB source object using the command-line interface.

 This process is currently supported only via CLI.

## Procedure

1. Log into the Delphix command-line interface using the admin user or a user with admin privileges.

```
$ ssh admin@YOUR_ENGINE
```

2. Move to the database.

```
delphix> sourcedelphix source> "VCDO_1JL"
```

3. Viewing all the settings using the "ls" command.

```
delphix source "VCDO_1JL" *> lsProperties      type: OracleVirtualPdbSource
name: VCDO_1JL      allowAutoVDBRestartOnHostReboot: false      archiveLogMode:
true      config: VCDO_1JL      configParams:      _cdb_disable_pdb_limit: TRUE

## CLI cookbook: replication

These topics describe how to use the command-line interface for replication tasks.

This section covers the following topics:

- [CLI cookbook: adding a replication spec](#)
- [CLI cookbook: deleting a replication spec](#)
- [CLI cookbook: failing over a namespace](#)
- [CLI cookbook: mapping replication Specs to Objects](#)
- [CLI cookbook: triggering immediate execution of a replication spec](#)

## CLI cookbook: adding a replication spec

This topic describes how to use the command-line interface to add a replication specification to the Delphix Engine.

Unlike the GUI, the CLI supports the ability to manage multiple replication specifications within a single system. This allows updates to be sent to multiple systems from a single point.

### Prerequisites

You should review the topic [Replication Overview](#) to understand which objects are copied as part of a backup or restore operation, as well as the dependencies between objects.

### Procedure

1. Switch to the replication spec context.

```
delphix> cd replication/spec
delphix replication spec> ls
Operations
create
```

2. Create a new replication spec.

```
delphix replication spec> create
delphix replication spec create *> ls
Properties
  type: ReplicationSpec
  name: (unset)
  bandwidthLimit: (unset)
  enabled: (unset)
  encrypted: (unset)
  objects: (required)
  schedule: (unset)
  targetCredential:
    type: PasswordCredential
    password: (required)
  targetHost: (required)
  targetPrincipal: (required)
```

3. Specify the target hostname, user, and credentials.

```
delphix replication spec create *> set targetHost=exampleHost.mycompany.com
delphix replication spec create *> set targetPrincipal=delphix_admin
delphix replication spec create *> set targetCredential.password=password
```

#### Info:

SDD Secure replication

To create a Selective Data Distribution (SDD) type spec set the objectSpecification.type

```
delphix replication spec create *> set
objectSpecification.type=ReplicationSecureList
```

This parameter defaults to ReplicationList which implies a regular replication spec.

**Warning:**

Target Principal

The target principal must be a Delphix user on the target host who has domain privileges.

4. Specify the set of objects to replicate.
  - a. To replicate all dSources and VDBs on the system, specify ``DOMAIN`` as the list of objects.

```
delphix replication spec create *> set objectSpecification.objects=`DOMAIN`
```

- b. To replicate a subset of Groups, VDBs, dSources, and Timeflows specify their names as a comma-separated list.

```
delphix replication spec create *> set objectSpecification.objects=Group1/
vdb1,Group2/vdb2
```

**Info:**

Name Completion

The CLI will provide possible completions for all objects in the system, but only groups, dSources and VDBs can be specified. Attempts to replicate other types of objects will generate an error when the operation is committed.

**Info:**

SSD Secure replication

If `objectSpecification.type=ReplicationSecureList` was selected, then

`objectSpecification.containers` needs to be used instead of `objectSpecification.objects`.

The containers have to be Masked VDBs

5. Commit the operation.

```
delphix replication spec create *> commit
`REPLICATION_SPEC-1
```

## CLI cookbook: deleting a replication spec

This topic describes how to use the command-line interface to delete a replication spec.

## Procedure

1. Switch to the replication spec context and list the specs on the system.

```
delphix> cd replication/spec
delphix replication spec> ls
Objects
REFERENCE          TARGETHOST
REPLICATION_SPEC-1 exampleHost.mycompany.com

Operations
create
```

2. Select the replication spec to remove.

```
delphix replication spec> select REPLICATION_SPEC-1
delphix replication spec "exampleHost.mycompany.com">
```

3. Remove the spec.

```
delphix replication spec "exampleHost.mycompany.com"> delete
delphix replication spec "exampleHost.mycompany.com" delete *> commit
```

## CLI cookbook: failing over a namespace

This topic describes how to use the command line interface to fail over a namespace.

### Procedure

1. Switch to the namespace context and list the namespaces on the system.

```
delphix> cd namespace
delphix namespace> ls
Objects
NAME
[172.16.203.93]

Operations
lookup
```

2. Select the namespace to failover.

```
delphix namespace> select [172.16.203.93]
delphix namespace "[172.16.203.93]">
```

3. Failover the namespace.

```
delphix namespace "[172.16.203.93]"> failover
delphix namespace "[172.16.203.93]" failover *> commit
```

### Failover

Failover will sever the replication connection and make objects in the namespace part of the live system. This will prevent the target from receiving subsequent incremental updates.

## CLI cookbook: mapping replication specs to objects

After creating replication specs often you will want to see what is mapping to which target, this document will show you how to find that information in the CLI. It will also show you how to navigate the replication directory in the CLI.

1. ssh into the CLI as a user with delphix\_admin privileges.

```
ssh admin@yourengine
```

2. Next go to the replication directory in the CLI and list all of the specs.

```
delphix > replication
delphix replication > spec
delphix replication spec > ls
Objects

REFERENCE          TARGETHOST

REPLICATION_SPEC-1 test1

Operations

create
```

3. Then select the replication spec to find where it maps to and what objects are selected with it.

```
delphix replication spec> select REPLICATION_SPEC-1
delphix replication spec 'test'> ls
Properties

  type: ReplicationSpec
  name: test
  bandwidthLimit: 0
  description: (unset)
  enabled: false
  encrypted: false
  numberOfConnections: 1
  objectSpecification:
```

```
  type: ReplicationList
  name: (unset)
  objects: Untitled/dbdhcp3
reference: REPLICATION_SPEC-1
runtime:
  type: ReplicationSpecRuntime
schedule: (unset)
tag: 0ddae174-9486-4363-9704-bfc3398e547e
targetCredential:
  type: PasswordCredential
  password: *****
targetHost: test1
targetPort: 8415
targetPrincipal: delphix
useSystemSocksSetting: false
```

#### Operations

delete

update

execute

## CLI cookbook: triggering immediate execution of a replication spec

This topic describes how to use the command-line interface to trigger an immediate execution of a replication spec in the Delphix Engine.

## Procedure

1. Switch to the replication spec context and list the specs on the system.

```
delphix> cd replication/spec
delphix replication spec> ls
Objects
REFERENCE          TARGETHOST
REPLICATION_SPEC-1 exampleHost.mycompany.com

Operations
create
```

2. Select the replication spec to execute.

```
delphix replication spec> select REPLICATION_SPEC-1
delphix replication spec "exampleHost.mycompany.com">
```

3. Execute the spec.

```
delphix replication spec "exampleHost.mycompany.com"> execute
delphix replication spec "exampleHost.mycompany.com" execute *> commit
  Dispatched job JOB-7
  REPLICATION_SEND job started.
  Connecting to target "exampleHost.mycompany.com".
  Preparing replication update.
  Starting incremental replication update.
  Sending metadata.
  Sending data for "Untitled".
  Sending data for "Untitled/redsox1".
  Transfer completed in 0:00:01, sent 1.39MB (1.39MB/s).
  Committing serialization state.
  REPLICATION_SEND job completed successfully.
```

## CLI cookbook: Delphix self-service actions

These entries will help with some of the Delphix Self-Service Actions that can be performed in the CLI and therefore with the Delphix APIs:

- [CLI cookbook: how to create a Delphix self-service bookmark](#)
- [CLI cookbook: how to create a Delphix self-service branch](#)
- [CLI cookbook: how to create a Delphix self-service container](#)
- [CLI cookbook: how to create a Delphix self-service database template](#)
- [CLI cookbook: how to create a Delphix self-service user](#)
- [CLI cookbook: how to delete a Delphix self-service bookmark](#)
- [CLI cookbook: how to delete a Delphix self-service container](#)
- [CLI cookbook: how to delete a Delphix self-service template](#)
- [CLI cookbook: how to refresh a Delphix self-service container](#)
- [CLI cookbook: how to share a Delphix self-service bookmark](#)
- [CLI cookbook: how to update a Delphix self-service bookmark](#)

## CLI cookbook: how to create a Delphix self-service bookmark

## Prerequisites:

- Have Delphix Self-Service user privileges.
- Know the branch you would like to create the bookmark on.
- Know the container or template that the branch belongs to.
- (Optional) Know when you would like the bookmark to expire.

Delphix Self-Service administrators can use this CLI cookbook recipe to create a bookmark on Delphix Self-Service using the Delphix Engine CLI.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [createBookmark.sh](#).

## Creating a bookmark in Delphix Self-Service

```
#!/bin/bash
# A sample script for calls to the CLI. This one creates a Jet Stream bookmark.
#
# VERY IMPORTANT: In order for this to work, you need to go through the steps here:
# https://docs.delphix.com/display/DOCS43/CLI+Cookbook%3A+Configuring+Key-
Based+SSH+Authentication+for+Automation
# After this you will not need to use a username and password to log into the delphix
engine. If you do not
# setup the SSH authentication you will have to manually enter the password.
#

##example##
#./createBookmark.sh -e "2016-07-27T23:38:56.453Z" -t "2016-07-27T01:45:56.453Z" -T
[tag1,tag2,tag3,tag4,tag5] bkmrk3 JS_BRANCH-41

##### Constants

# Describes a Delphix software revision.

CLI cookbook: how to create a Delphix self-service branch

Delphix Self-Service administrators can use this CLI cookbook recipe to create a branch on Delphix Self-Service using the Delphix Engine CLI.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [createBranch.sh](#).

Creating a branch in Delphix Self-Service

```
#!/bin/bash

# A sample script for calls to the CLI. This one creates a Jet Stream branch.
#
# VERY IMPORTANT: In order for this to work, you need to go through the steps here:
# https://docs.delphix.com/display/DOCS43/CLI+Cookbook%3A+Configuring+Key-Based+SSH+Authentication+for+Automation
# After this you will not need to use a username and password to log into the delphix engine. If you do not
# setup the SSH authentication you will have to manually enter the password.
#
# Note that the CLI only allows branches to be created from below
# 1) From latest point in time
# 2) From specific bookmark
# 3) From specific point in time

##examples##
# Create branch from latest point in time
./createBranch.sh NewBranchName JS_DATA_CONTAINER-20
# Create branch from specific bookmark
./createBranch.sh -b ExistingBookmarkName NewBranchName JS_DATA_CONTAINER
# Create branch from specific point in time
./createBranch.sh -t "2016-07-27T01:45:56.453Z" -B JS_BRANCH-2 NewBranchName JS_DATA_CONTAINER-20

## CLI cookbook: how to create a Delphix self-service container

Delphix Self-Service administrators can use this CLI cookbook recipe to create a container on Delphix Self-Service using the Delphix Engine CLI.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting createContainer.sh.

## Creating a container in Delphix self-service container

```
#!/bin/bash

# A sample script for calls to the CLI. This one creates a Jet Stream container.
#
# VERY IMPORTANT: In order for this to work, you need to go through the steps here:
# https://docs.delphix.com/display/DOCS43/CLI+Cookbook%3A+Configuring+Key-Based+SSH+Authentication+for+Automation
# After this you will not need to use a username and password to log into the delphix
# engine. If you do not
# setup the SSH authentication you will have to manually enter the password.
#

##### Constants

# Describes a Delphix software revision.
VERSION="1.11.10"

##### Default Values. These can be overwritten with optional arguments.
engine="name-of-engine.dlpxdc.co"
username="admin"

##examples##
# Create container from latest point in time
#./createContainer.sh -n "testsource" testcont ORACLE_DB_CONTAINER-269
# JS_DATA_TEMPLATE-13
# Create container from specific bookmark
#./createContainer.sh -n "testsource" -b JS_BOOKMARK-77 testcont ORACLE_DB_CONTAINER-2
# 69 JS_DATA_TEMPLATE-13
# Create container from specific point in time
#./createContainer.sh -n "testsource" -t "2016-08-08T10:00:00.000Z" -B JS_BRANCH-50
# testcont ORACLE_DB_CONTAINER-269 JS_DATA_TEMPLATE-13

#NOTE: this script will add one container and assign one owner for the container.

## CLI cookbook: how to delete a Delphix self-service bookmark

## Prerequisites:

- Have Delphix Self-Service user privileges
- Know the bookmark you would like to delete

## Procedure:

1. Log into Delphix Engine as a Delphix Self-Service user or admin.

```
ssh jsUser@<yourengine>
```

2. Navigate to the Delphix Self-Service bookmarks, and choose the one you would like to delete.

```
jsUser > selfservice  
bookmark  
jsUser selfservice bookmark > ls  
jsUser selfservice bookmark > select <jsBookmark>
```

3. Delete the bookmark.

```
jsUser selfservice bookmark <jsBookmark> *> delete  
jsUser selfservice bookmark <jsBookmark> delete *> commit
```

## CLI cookbook: how to delete a Delphix self-service container

## Prerequisites:

- Know the container you want to delete
- Have delphix\_admin privileges

## Procedure:

1. Log into Delphix Engine as admin

```
ssh delphix@<yourengine>
```

2. Navigate to the Delphix Self-Service container that you want to delete

```
delphix > selfservice container  
delphix selfservice container > ls  
delphix selfservice container > select CONTAINER_X  
delphix selfservice container 'CONTAINER_X' >
```

3. Delete container, **note you need to set if you want to delete the VDBs in the container (false will preserve the VDBs and true the VDBs will be deleted along with the container)**

```
delphix selfservice container 'CONTAINER_X' > delete  
delphix selfservice container 'CONTAINER_X' delete * > set deleteDataSources=<true/false>  
delphix selfservice container 'CONTAINER_X' delete * > commit
```

## CLI cookbook: how to delete a Delphix self-service template

## Prerequisites:

- Template has no dependant containers
- Know the name of the template you are going to delete
- Have delphix\_admin privileges (note JetStream Only users and Delphix GUI Owners cannot delete templates)

## Procedure:

1. Log into your Delphix Engine using delphix\_admin (or admin privileged account)

```
ssh delphix_admin@<youengine>
```

2. Find the template you want to delete

```
delphix > selfservice  
delphix selfservice template > ls  
delphix selfservice template > select 'TEMPLATE_X'  
delphix selfservice template 'TEMPLATE_X'>
```

3. Delete template and commit

```
delphix selfservice template 'TEMPLATE_X'> delete  
delphix selfservice template 'TEMPLATE_X' delete *> commit
```

## CLI cookbook: how to refresh a Delphix self-service container

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [refreshContainer.sh](#).

## Refreshing a container in Delphix self-service

```
#!/bin/bash

# A sample script for calls to the CLI. This one refresh Jet Stream container.
#
# VERY IMPORTANT: In order for this to work, you need to go through the steps here:
# https://docs.delphix.com/display/DOCS43/CLI+Cookbook%3A+Configuring+Key-
Based+SSH+Authentication+for+Automation
# After this you will not need to use a username and password to log into the delphix
engine. If you do not
# setup the SSH authentication you will have to manually enter the password.
#

## CLI cookbook: how to share a Delphix self-service bookmark

## Prerequisites:

- Have Delphix Self-Service user privileges.
- Know the bookmark you would like to share.

Delphix Self-Service administrators can use this CLI cookbook recipe to share a bookmark on Delphix Self-Service using the Delphix Engine CLI.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [shareBookmark.sh](#).

## Sharing a bookmark in Delphix self-service

```
#!/bin/bash

# A sample script for calls to the CLI. This one shares Bookmark across containers in
# same template.
#
# VERY IMPORTANT: In order for this to work, you need to go through the steps here:
# https://docs.delphix.com/display/DOCS43/CLI+Cookbook%3A+Configuring+Key-
Based+SSH+Authentication+for+Automation
# After this you will not need to use a username and password to log into the delphix
# engine. If you do not
# setup the SSH authentication you will have to manually enter the password.
#

## CLI cookbook: how to update a Delphix self-service bookmark

## Prerequisites:

- Have Delphix Self-Service user privileges
- Know the bookmark you would like to update

## Procedure:

1. Log into Delphix Engine as a Delphix Self-Service user or admin.

```
ssh jsUser@<yourengine>
```

2. Navigate to the Delphix Self-Service bookmarks, and choose the one you would like to update.

```
jsUser > selfservice bookmark  
jsUser selfservice bookmark > ls  
jsUser selfservice bookmark > select <jsBookmark>
```

3. Update the bookmark.

```
jsUser selfservice bookmark <jsBookmark> *> update  
jsUser selfservice bookmark <jsBookmark> update *> set tags="tag text"  
jsUser selfservice bookmark <jsBookmark> update *> commit
```

## CLI cookbook: hooks and hook templates

These topics describe the command-line interface procedures for working with hooks and hook templates.

This section covers the following topics:

- [CLI cookbook: changing the PowerShell version associated with a hook template](#)

## CLI cookbook: changing the PowerShell version associated with a hook template

This article is to document how to change the PowerShell version associated with a hook template using the CLI.

 This operation is not allowed through GUI.

## Procedure:

1. Login into Delphix Engine CLI using "admin" credentials.

```
ssh admin@<delphix_engine>
```

2. Go to **source** and then to **operationTemplate**.

```
delphix> source
delphix source> operationTemplate
```

3. Execute the **ls** command to see the existing hooks template and select one of the existing hook templates which you want to update.

```
delphix source operationTemplate> ls
Objects
NAME                DESCRIPTION                LASTUPDATED
OPERATION.TYPE
Test_Template        Test_Template              2020-06-12T04:15:01.759Z
RunDefaultPowerShellOnSourceOperation

delphix source operationTemplate> select Test_Template

delphix source operationTemplate 'Test_Template'> ls
Properties
  type: OperationTemplate
  name: Test_Template
  description: Test_Template
  lastUpdated: 2020-06-12T04:15:01.759Z
  operation:
    type: RunDefaultPowerShellOnSourceOperation
    name: Test_Template
    command: echo_command
    reference: OPERATION_TEMPLATE-1
```

4. Run the **update** command and change the hook template type from **RunDefaultPowerShellOnSourceOperation** to **RunPowerShellOnSourceOperation**.  
**Note:** Users can also change the template type from **RunPowerShellOnSourceOperation** to **RunDefaultPowerShellOnSourceOperation**.

```
delphix source operationTemplate 'Test_Template'> update
```

```
delphix source operationTemplate 'Test_Template' update *> set
operation.type=RunPowerShellOnSourceOperation
delphix source operationTemplate 'Test_Template' update *> ls
Properties
  type: OperationTemplate
  name: Test_Template
  description: Test_Template
  operation:
    type: RunPowerShellOnSourceOperation (*)
    name: Test_Template
    command: echo_command
```

5. Run the **commit** command to perform the update on the hook template. Execute the **ls** command again to see the change in the hook template type.

```
delphix source operationTemplate 'Test_Template' update *> commit

delphix source operationTemplate 'Test_Template'> ls
Properties
  type: OperationTemplate
  name: Test_Template
  description: Test_Template
  lastUpdated: 2020-06-12T04:30:44.203Z
  operation:
    type: RunPowerShellOnSourceOperation
    name: Test_Template
    command: echo_command
  reference: OPERATION_TEMPLATE-1
```

1. Template type can only be changed from "RunDefaultPowerShellOnSourceOperation" to "RunPowerShellOnSourceOperation" or vice versa. You **can not** change the type to other available types. If you try to do that, you will get this error: "Error: The type of this operation (RUN\_POWERSHELL\_ON\_SOURCE\_OPERATION) cannot be modified after creation.".
2. Template type "RunPowerShellOnSourceOperation" denotes "PowerShell version 2" and "RunDefaultPowerShellOnSourceOperation" denotes "Default PowerShell version". Here, default version is the version of PowerShell installed on the target host.

## CLI cookbook: network performance

These topics describe command-line interface procedures using the iperf-based Network Performance Tool:

- [CLI cookbook: Delphix session protocol test from primary engine to replication engine](#)
- [CLI cookbook: running the network test via CLI - latency](#)
- [CLI cookbook: running the network test via CLI - throughput](#)

## CLI cookbook: Delphix session protocol test from primary engine to replication engine

### Prerequisites

The network performance tool measures network performance between a Delphix Engine and an environment host. You must have added an environment in order to use this tool.

This transmission control protocol (TCP) throughput test uses TCP port 50001 by default. The port can also be configured on a per-test-run basis. For the duration of a given throughput test, a server on the receiver will be listening on this port. For a transmit test, the receiver is the remote host; for a receive test, the receiver is the Delphix Engine

### Procedure

Delphix uses the Delphix Session Protocol (DSP) protocol to communicate between primary and replication engines.

1. Login to Delphix Engine using a Delphix administrator account such as **delphix\_admin**. As soon as you login, you will get prompt with engine name.

```
-bash-4.3$ ssh delphix_admin@delphix
Password:
delphix>
```

2. Create a DSP test.

```
delphix> network test dsp create
```

3. Set the destinationType to DELPHIX\_ENGINE to do a DSP test between two Delphix Engines. The default is REMOTE\_HOST which executes a DSP test between a source or target host and the Delphix Engine.

```
delphix network test dsp create *> set destinationType=DELPHIX_ENGINE
```

4. Use **get** to see other optional arguments. Modify the test parameters as needed and commit to start the test.

```
delphix network test dsp create *> get
type: NetworkDSPTestParameters
blockSize: 64KB
compression: false
destinationType: REMOTE_HOST
direction: TRANSMIT
duration: 30
encryption: false
numConnections: 0
queueDepth: 32
receiveSocketBuffer: 256KB
remoteDelphixEngineInfo: (unset)
remoteHost: (unset)
sendSocketBuffer: 256KB
delphix network test dsp create *> set remoteDelphixEngineInfo.address=delphix2
```

```

delphix network test dsp create *> set
remoteDelphixEngineInfo.principal=delphix_admin
delphix network test dsp create *> edit remoteDelphixEngineInfo
delphix network test dsp create remoteDelphixEngineInfo *> get
  type: RemoteDelphixEngineInfo (*)
  address: delphix2 (*)
  credential: (required)
  principal: delphix_admin (*)
delphix network test dsp create remoteDelphixEngineInfo *> set
credential.password=delphix
delphix network test dsp create remoteDelphixEngineInfo *> commit

```

## CLI cookbook: running the network test via CLI - latency

## Prerequisites

The network performance tool measures network performance between a Delphix Engine and an environment host. You must have added an environment in order to use this tool.

This transmission control protocol (TCP) throughput test uses TCP port 50001 by default. The port can also be configured on a per-test-run basis. For the duration of a given throughput test, a server on the receiver will be listening on this port. For a transmit test, the receiver is the remote host; for a receive test, the receiver is the Delphix Engine.

## Procedure

The network latency test measures network round-trip latency by transmitting ICMP echo requests (like the ping utility) and measuring the time to receive replies from the remote host. To execute a test:

1. Login as a domain user to the Delphix Engine CLI using ssh.
2. Create a network latency test.

```
delphix> network test latency
delphix network test latency> create
delphix network test latency create *>
```

3. You must set **remoteHost** to the name of an environment host already configured in the Delphix Engine. (You should press tab after the "=" (equal sign) to auto-populate and confirm registered destinations). Use 'get' to see other optional arguments. Modify the test parameters as needed and **commit** to start the test.

```
delphix network test latency create *> set remoteHost=oracletarget
delphix network test latency create *> get
  type: NetworkLatencyTestExecuteParameters
  remoteHost: oracletarget
  requestCount: 20
  requestSize: 8B
delphix network test latency create *> commit
  Dispatched job JOB-20

## CLI cookbook: running the network test via CLI - throughput

### Prerequisites

The network performance tool measures network performance between a Delphix Engine and an environment host. You must have added an environment in order to use this tool.

This transmission control protocol (TCP) throughput test uses TCP port 50001 by default. The port can also be configured on a per-test-run basis. For the duration of a given throughput test, a server on the receiver will be listening on this port. For a transmit test, the receiver is the remote host; for a receive test, the receiver is the Delphix Engine.

### Procedure

The network throughput test measures sustained throughput using a synthetic workload to or from a remote host. To execute a test:

1. Login as a domain user to the **Delphix Engine CLI** using ssh.
2. Create a network throughput test.

```
delphix> network test throughput
delphix network test throughput> create
delphix network test throughput create *>
```

3. You must set **remoteHost** to the name of an environment host already configured in the Delphix Engine. Use 'get' to see other optional arguments. Modify the test parameters as needed and **commit** to start the test.

```
delphix network test throughput create *> set remoteHost=oraclesource
delphix network test throughput create *> ls
Properties
  type: NetworkThroughputTestParameters
  blockSize: 128KB
  direction: TRANSMIT
  duration: 30
  numConnections: 0
  port: 50001
  receiveSocketBuffer: 4MB
  remoteHost: oraclesource
  sendSocketBuffer: 4MB
delphix network test throughput create *> commit
  Dispatched job JOB-21

## Web services API guide

These topics describe interfacing with the public web service APIs, building automation facilities and integrating with third-party orchestration tools.

This section covers the following topics:

- [API version information](#)
- [Web service object model](#)
- [Web service protocol](#)
- [CLI to web services translation](#)
- [GUI API mapping](#)
- [CLI to Python transition](#)
- [Python Cookbook: adding a UNIX host](#)
- [So you want to work with Delphix APIs?](#)
- [API Cookbook: common tasks, workflows, and examples](#)
- [Kerberos APIs](#)

## API version information

This topic describes API version information for each release of the Delphix Engine, including schema changes and links to the relevant version of the schema.

<b>Delphix engine version</b>	<b>API version</b>	<b>Link to schema within the appliance</b>
5.0.0.x - 5.0.3.x	1.7.0	<a href="http://&lt;engine-address&gt;/api/json/versions/1.7.0/delphix.json">http://&lt;engine-address&gt;/api/json/versions/1.7.0/delphix.json</a>
5.0.4.x	1.7.1	<a href="http://&lt;engine-address&gt;/api/json/versions/1.7.1/delphix.json">http://&lt;engine-address&gt;/api/json/versions/1.7.1/delphix.json</a>
5.1.0.x - 5.1.2.x	1.8.0	<a href="http://&lt;engine-address&gt;/api/json/versions/1.8.0/delphix.json">http://&lt;engine-address&gt;/api/json/versions/1.8.0/delphix.json</a>
5.1.3.x - 5.1.5.x	1.8.1	<a href="http://&lt;engine-address&gt;/api/json/versions/1.8.1/delphix.json">http://&lt;engine-address&gt;/api/json/versions/1.8.1/delphix.json</a>

For more details see [API Changes](#)

## Web service object model

This topic describes the Delphix object model as exported over the web services.

### Object types

All objects in the Delphix API are "typed objects." All such objects have a `type` field that indicates the type of the object and its associated semantics. This allows for object inheritance and polymorphism without requiring separate APIs for each type and allows generic client-specific semantic encoding and decoding without having to be aware of the context. This means that even APIs that operate only a specific type (such as the `Group` API) still require a type field to be specified as part of the input, and will continue to report the type of objects when listing or retrieving objects. This allows the APIs to evolve in a backward-compatible fashion through the introduction of new types.

Certain "root" object types (groups, containers, sources, etc) have an associated API. This API is rooted at a particular point under `/resources/json/delphix`, but all APIs follow a standard format beneath this namespace. The CLI namespace is a direct reflection of this URL, and the API reference has an index both by object type as well as by object (CLI) path. These APIs may operate on different extended types (such as `OracleSIConfig` and `OracleRACConfig`), but the base operations remain the same regardless of input type.

### Object references

Some objects returned by the APIs are pure typed objects, in that they don't represent the persistent state on the Delphix Engine but are rather calculated and returned upon request. Most of the objects in the system, however, are "persistent objects." Persistent objects (of type `PersistentObject`) have a stable reference that uniquely identifies the object on the system. This reference is separate from its name so that objects can be renamed without affecting the programmatic API. More information about object names and how they can be represented generically can be found in the [CLI documentation](#). Object references are opaque tokens; while they can be stored and reused for later use, and interpretation of their contents is unstable and may break in a future release.

The Delphix object hierarchy is stitched together by these object references. When fetching an object that refers to another object, the member will be returned as a reference, rather than being inserted directly within the parent object. This allows consumers to control when and how links are resolved and make it clear when an object may change independently from its parent. The per-object APIs outlined below all operate on object references.

Note that some Delphix objects are `singleton` objects, and there is only one such object on the system. These objects do not have references because the API URL uniquely identifies the object on the system.

### API operations

All APIs optionally support the following operations:

- `CREATE` - Create a new instance of the given object type. This is used for most objects, but more complicated objects, such as `dSources` and `VDBs`, must be created through a dedicated `link` or `provision` operation. The input to this operation is typically the object itself, though some objects may have specialized parameters used during the creation of objects. An example of this is `HostEnvironmentCreateParameters`.
- `UPDATE` - Update properties of the given object, specified as an object reference in the URL.

- **DELETE** - Delete a particular object, specified as an object reference in the URL. These operations are typically done as HTTP **DELETE** operations, but it is also possible to do a **POST** operation to the `/delete` API to do the same thing. The **POST** form allows for delete-specific parameters, such as `OracleDeleteParameters`.
- **GET** - Get the properties for a particular object, specified as an object reference in the URL.
- **LIST** - List all objects of the given type within the system. These APIs typically take optional query parameters that allow the set of results to be constrained, filtered, paginated, or sorted.

In addition, the following non-CRUD operations may be supported:

- **Root Operation** - A **POST** or **GET** operation to the root of an API namespace, not associated with a particular object. This can be used for singleton objects, such as `NDMPConfig`, operations that create objects, such as `Link`, and operations that operate on multiple objects at once.
- **Per-object Operation** - A **POST** operation to a particular object reference. These operations are typically read-write but are not required to be so. These would include read-only operations that cannot be modeled as CRUD operations or require complex input use per-object operations.

## Database object mModel

In order to support a wide variety of databases and database configurations, the database object model is more complex than it may initially appear after having used the Delphix Management application. For example, there is no such thing as a "dSource" or "VDB" object, only data "containers" with attached "sources". More information about how Database objects are modeled within Delphix can be found in the [CLI documentation](#)

## Asynchronous execution

All APIs are designed to be transactionally safe and "quick." However, there are operations that may take a long period of time or may need to reach out to external hosts or databases such that they cannot be done safely within the context of a single API call. Such operations will dispatch a `Job` to handle asynchronous execution of the operation. **Any API** can potentially spawn a job, and which APIs spawn jobs and which do not may differ between object types or releases. If you are developing a full-featured automation system, it is recommended that you build a generic infrastructure to handle job monitoring, rather than encoding the behavior of particular APIs that may change over time.

Every operation, except for `LIST` and `GET`, which are guaranteed to be read-only, can potentially spawn a job.

This is represented by the `job` field of the `APIResult` object. If this field is `null`, then the action can be completed within the bounds of the API call. Otherwise, a reference to a dispatched job is returned.

Jobs can spawn other jobs for especially complex operations, such as provisioning to an Oracle cluster environment. The job returned in the API invocation is the root job, and overall success or failure of the operation is determined by the state of this job. Some operations may succeed even if a child job fails. An example would be provisioning to an Oracle cluster where one node failed, but others were successful.

Progress can be monitored by examining the `JobEvent` objects in the `Job` object returned through the job API.

## Web service protocol

This topic describes an overview of the web service API and available facilities.

### Introduction

The Delphix Engine provides a set of public stable web service APIs (application programming interfaces). The web services form the basis upon which the GUI and CLI are built, and are designed to be **public** and **stable**. This guide covers the basic operation of the protocol, concepts, and considerations when building layered infrastructure. It is not a reference for all available APIs. For more information on available APIs, go to the '/api' URL of a Delphix appliance, which will provide a complete reference of all available APIs for the version of Delphix running on that system.

```
http://<server>/api
```

The CLI is a thin veneer over the web services. If you are new to the web services, it is recommended you first test out operations with the CLI, and use the `setopt trace=true` option to dump the raw data being sent and received to see the API in action.

### Protocol operation

The Delphix web services are a [RESTful](#) API with loose [CRUD](#) semantics using [JSON](#) encoding.

The following HTTP methods are supported:

- `GET` - Retrieve data from the server where complex input is not needed. All `GET` requests are guaranteed to be read-only, but not all read-only requests are required to use `GET`. Simple input (strings, number, boolean values) can be passed as query parameters.
- `POST` - Issue a read/write operation, or make a read-only call that requires complex input. The optional body of the call is expressed as JSON.
- `DELETE` - Delete an object on the system. For languages that don't provide a native wrapper for `DELETE`, or for delete operations with optional input, all delete operations can also be invoked as `POST` to the same URL with `/delete` appended to it.

Regardless of the operation, the result is returned as a JSON encoded result, the contents of which are covered below. For example, the following invocation of `curl` demonstrates establishing a new Session (pretty-printing the result):

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/session \
-c ~/cookies.txt -H "Content-Type: application/json" <<EOF{  "type": "APISession",
"version": {      "type": "APIVersion",      "major": 1,      "minor": 4,
"micro": 3      }}EOF{  "status":"OK",  "result": {      "type":"APISession",
"version": {      "type": "APIVersion",      "major": 1,      "minor":
4,      "micro": 3      },      "locale": "en_US",      "client": null  },
"job": null}EOF
```

NOTE: It is generally recommended to set the API session version to the [highest level supported](#) by your Delphix Engine.

## Session establishment

Login involves establishing a session and then authenticating to the Delphix Engine. Only authenticated users can access web APIs. Each user must establish a session prior to making any other API calls. This is done by sending a `Session` object to the URL `/resources/json/delphix/session`. This session object will specify the `APIVersion` to use for communication between the client and server. If the server doesn't support the version requested due to an incompatible change reflected in the API major version number, an error will be returned.

The resulting session object encodes the native server version, which can be different than the version requested by the client. If the server is running a more recent but compatible version, any translation of input and output to the native version is handled automatically. More information on versioning can be found in the documentation for the `APIVersion` object within the API reference on a Delphix system. If the client supports multiple versions, the appropriate type can be negotiated by trying to establish a session with each major version supported and then inspecting the version returned.

The session will also return an identifier through browser cookies that can be reused in subsequent calls to use the same session credentials and state without having to re-authenticate. The format of this cookie is private to the server and may change at any point. Sessions do not persist across a server restart or reboot. The mechanism by which this cookie is preserved and sent with subsequent requests is client-specific. The following demonstrates invoking the session login API call using `curl` and storing the cookies in the file `~/cookies.txt` for later use:

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/session \
-c ~/cookies.txt -H "Content-Type: application/json" <<EOF{  "type": "APISession",
"version": {      "type": "APIVersion",      "major": 1,      "minor": 4,
"micro": 3    }}EOF{  "status": "OK",  "result": {      "type": "APISession",
"version": {      "type": "APIVersion",      "major": 1,      "minor":
4,      "micro": 3    },      "locale": "en_US",      "client": null  },
"job": null}EOF
```

## Authentication

Once the session has been established, the next step is to authenticate to the server by executing the `LoginRequest` API. Unauthenticated sessions are prohibited from making any API calls other than this login request. The username can be either a system user or domain user, and the backend will authenticate using the appropriate method. This example illustrates logging in via `curl` using cookies created when the session was established:

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/login \-b
cookies.txt -c cookies2.txt -H "Content-Type: application/json" <<EOF{"type":
>LoginRequest", "username": "delphix_user", "password": "delphix_pass", "target":
"DOMAIN"}EOF
```

The new cookie (`cookies2.txt`) will need to be used in subsequent API requests. The login API currently only supports authentication by a password. There is no way to authenticate using any shared key or alternate authentication strategy.

## CLI to web services translation

This topic describes using the CLI to understand public web service APIs.

The [command-line interface](#) is a direct translation of the web services API to an interactive environment. This allows you to use the CLI to explore functionality with tab completion, integrated help, stronger type checking, and an indication of expected types and required fields. When trying to determine how to invoke an operation through the web services or interpret the results, it is recommended that you first learn how to do the same through the CLI, and then use the provided tools to translate that into web services call.

### CLI translation to HTTP

The CLI namespace is identical to the web service URLs for each base object and operation type. The root of all web services is `/resources/json/delphix`. Any additional CLI context is appended to this URL, joined by slashes. For example:

```
delphix> database provision
```

Is equivalent to:

```
POST /resources/json/delphix/database/provision
```

All operations in the CLI (those that require an explicit `commit` command) are modeled as `POST` HTTP calls. This is an example of a "root operation", as they are invoked not on any particular object, but across the system as a whole. Operations that are invoked on a particular object use a URL specific to that object:

```
delphix> database "dexample" refresh
```

Is equivalent to:

```
POST /resources/json/delphix/database/ORACLE_DB_CONTAINER-3/refresh
```

While the CLI uses names to refer to objects, at the API level we use references. Persistent objects (those with a permanent unique identity) have a `reference` field that is used in all cases to refer to the object. This allows references to remain constant even if objects are renamed.

For the standard CRUD (create, read, update, delete) operations, the mapping is slightly different:

CLI operation	HTTP API
<code>database list</code>	<code>GET /resources/json/delphix/database</code>
<code>database create</code>	<code>POST /resources/json/delphix/database</code>
<code>database "dexample" get</code>	<code>GET /resources/json/delphix/database/&lt;&gt;</code>

CLI operation	HTTP API
<pre>database "dexample" update</pre>	<pre>POST /resources/json/delphix/database/&lt;&gt;</pre>
<pre>database "dexample" delete</pre>	<pre>DELETE /resources/json/delphix/database/&lt;&gt; POST /resources/json/delphix/database/&gt;&gt;</pre>

The `DELETE` operation has an optional `POST` form that can take complex input for clients that don't support sending a payload as part of a `DELETE` operation.

## Tracing HTTP calls

The CLI also provides facilities to see the raw HTTP calls being made as part of any operation. To start with, viewing data in JSON format ( `setopt format=json` ) will provide an example of what the raw output looks like from the server. In its raw form, the CLI does not make any attempt to interpret the results, so references are displayed as references (and not names), and sizes are displayed as their raw numeric value.

This is helpful for scripting, but the CLI also has a mode to display the requests being sent to the server, the responses received, and the URLs used. To enable this mode, run `setopt trace=true` . Once you have determined how to do something through the CLI, you can use this mode as the basis for building direct integration with the raw HTTP APIs.

```
delphix group> setopt trace=true
delphix group> create
delphix group create *> set name=example
delphix group create *> set description="this is an example"
delphix group create *> commit
=== POST /resources/json/delphix/group ===
{
  "type": "Group",
  "name": "example",
  "description": "this is an example"
}
=== RESPONSE ===
{
  "status": "OK",
  "result": "GROUP-3",
  "action": "ACTION-37",
  "job": null
}
=== END ===
GROUP-3
delphix group> "example"
delphix group "example"> delete
=== GET /resources/json/delphix/group/GROUP-3 ===
=== RESPONSE ===
{
```

```
"status": "OK",
"result": {
  "type": "Group",
  "reference": "GROUP-3",
  "namespace": null,
  "name": "example",
  "description": "this is an example"
},
"action": null,
"job": null
}
=== END ===
delphix group "example" delete *> commit
=== POST /resources/json/delphix/group/GROUP-3/delete ===
{}
=== RESPONSE ===
{
  "status": "OK",
  "result": "",
  "action": "ACTION-38",
  "job": null
}
=== END ===
delphix group>
```

When using trace mode within the context of a specific object, we refresh the contents of the object before executing each command. This results in the `GET` request before the `delete` command in the above example.

## GUI API mapping

This topic describes how to map from GUI operations to the corresponding CLI operation.

It is not always straightforward to convert from the visual layout of the GUI to the corresponding CLI operations. This topic outlines some common operations and indicates how they are represented in the CLI, web services, and the API documentation.

### dSource operations

GUI	CLI	API topic	Input object	Web services
Link	database link	Container	LinkParameters	POST /resources/json/delphix/database/link
Show configuration	database "name" get source "name" get	Container Source	-	GET /resources/json/delphix/database/{ref} GET /resources/json/delphix/source/{ref}
Sync	database "name" sync	Container	SyncParameters	POST /resources/json/delphix/database/{ref}/sync
Update	database "name" update	Container	Container	POST /resources/json/delphix/database/{ref}
Delete	database "name" delete	Container	DeleteParameters	POST /resources/json/delphix/database/{ref}/delete
Detach	database "name" detachSource	Container	DetachSourceParameters	POST /resources/json/delphix/database/{ref}/detachSource

GUI	CLI	API topic	Input object	Web services
Attach	database "name" attachSource	Container	AttachSourceParameters	POST /resources/json/delphix/database/{ref}/attachSource
Disable	source "name" disable	Source	SourceDisableParameters	POST /resources/json/delphix/source/{ref}/disable
Enable	source "name" enable	Source	SourceEnableParameters	POST /resources/json/delphix/source/{ref}/enable

### VDB operations

GUI	CLI	API topic	Input object	Web services
Provision	database provision	Container	ProvisionParameters	POST /resources/json/delphix/database/provision
V2P	database export	Container	ExportParameters	POST /resources/json/delphix/database/export
Refresh	database "name" refresh	Container	RefreshParameters	POST /resources/json/delphix/database/{ref}/refresh
Snapshot	database "name" sync	Container	SyncParameters	POST /resources/json/delphix/database/{ref}/sync
Update	database "name" update	Container	Container	POST /resources/json/delphix/database/{ref}

GUI	CLI	API topic	Input object	Web services
Delete	database "name" delete	Container	DeleteParameters	POST /resources/json/delphix/database/{ref}/delete
Start	source "name" start	Source	StartParameters	POST /resources/json/delphix/source/{ref}/start
Stop	source "name" stop	Source	StopParameters	POST /resources/json/delphix/source/{ref}/stop
Enable	source "name" enable	Source	SourceEnableParameters	POST /resources/json/delphix/source/{ref}/enable
Disable	source "name" disable	Source	SourceDisableParameters	POST /resources/json/delphix/source/{ref}/disable

## Environment operations

GUI	CLI	API topic	Input object	Web services
Add environment	environment create	SourceEnvironment	SourceEnvironmentCreateParameters	POST /resources/json/delphix/environment
Update	environment "name" update	SourceEnvironment	Environment	POST /resources/json/delphix/environment/{ref}
Delete	environment "name" delete	SourceEnvironment	-	DELETE /resources/json/delphix/environment/{ref}

GUI	CLI	API topic	Input object	Web services
Refresh	environment "name" refresh	SourceEnvironment	-	POST /resources/json/delphix/environment/{ref}/refresh
Enable	environment "name" enable	SourceEnvironment	-	POST /resources/json/delphix/environment/{ref}/enable
Disable	environment "name" disable	SourceEnvironment	-	POST /resources/json/delphix/environment/{ref}/disable
Add manual repository	repository create	SourceRepository	SourceRepository	POST /resources/json/delphix/repository
Update repository	repository "name" update	SourceRepository	SourceRepository	POST /resources/json/delphix/repository/{ref}
Remove manual repository	repository "name" delete	SourceRepository	-	DELETE /resources/json/delphix/repository/{ref}
Show host details	host "name" get	Host	-	GET /resources/json/delphix/host/{ref}
Add cluster node	environment oracle clusternode create	OracleClusterNode	OracleClusterNode	POST /resources/json/delphix/environment/oracle/clusternode

GUI	CLI	API topic	Input object	Web services
Update cluster node	environment oracle clusternode "name" update	OracleClusterNode	OracleClusterNode	POST /resources/json/delphix/environment/oracle/clusternode/{ref}
Remove cluster node	environment oracle clusternode "name" delete	OracleClusterNode	-	DELETE /resources/json/delphix/environment/oracle/clusternode/{ref}
Add listener	environment oracle listener create	OracleListener	OracleListener	POST /resources/json/delphix/environment/oracle/listener
Update listener	environment oracle listener "name" update	OracleListener	OracleListener	POST /resources/json/delphix/environment/oracle/listener/{ref}
Remove listener	environment oracle listener "name" delete	OracleListener	-	DELETE /resources/json/delphix/environment/oracle/listener/{ref}

## CLI to Python transition

This topic describes using the CLI to understand the Python APIs.

The [command-line interface](#) is a direct translation of the web services API to an interactive environment. This allows you to use the CLI to explore functionality with tab completion, integrated help, stronger type checking, and indication of expected types and required fields. When trying to determine how to invoke an operation through the Python API or interpret the results, it is recommended that you first learn how to do the same through the CLI, and then use the provided tools to translate that into Python calls.

### Installation

The Delphix Python API is available through PyPI and you may install it with pip.

```
pip install delphixpy
```

**⚠ Minimum python version**  
Requiring Version 2.7 and above

### Connecting to the Delphix engine

In the Delphix Python API, all operations take an engine object which represents your connection to a Delphix Engine. Here is how you connect to the Delphix Engine using the Python API and acquire the engine object.

```
from delphixpy.delphix_engine import DelphixEngineengine = DelphixEngine("delphix-  
address", "delphix-user", "delphix-password", "DOMAIN") # Instead of DOMAIN, use  
SYSTEM if you are using the sysadmin user.
```

### CLI translation to Python

For backward compatibility purposes, delphixpy provides the ability to write integrations against a specific API version. The latest version is always in the root of the package. Writing against the latest version requires you to update your integrations if the API changes in future versions of the API.

Specific API versions can be used by importing the corresponding sub-package. The sub-packages are named after the API versions in the format `v<major>_<minor>_<micro>`. For example, if you want to look into API 1.5.0, you should be using modules from `delphixpy.v1_5_0`. Modules from different sub-package versions cannot interact with each other so be careful if you wish to mix API versions in the same code base.

All CLI namespaces have a corresponding Python package in which operations can be accessed. The main Python package is called `web`. All value objects which can be manipulated or read through the CLI can be found in `web.vo`.

```
delphix> database provision
```

Is equivalent to:

```
from delphixpy.web import databasedatabase.provision(engine, provision_parameters)
```

The `provision_parameters` object in this example is an instance of `ProvisionParameters` which can be found in `delphixpy.web.vo`. The properties of the object map to the parameters you would need to specify before doing a commit in the CLI provision context.

This is an example of an "operation", as they are invoked on an object. Operations that are invoked on a particular object take a reference to that object.

```
delphix> database "dexample" refresh
```

Is equivalent to (connection code omitted):

```
from delphixpy.web import databasedatabase.refresh(engine, "ORACLE_DB_CONTAINER-3",
RefreshParameters)
```

While the CLI uses names to refer to objects, the Python API, just like the web services, use references (`ORACLE_DB_CONTAINER-3`). Persistent objects (those with a permanent unique identity) have a `reference` field that is used in all cases to refer to the object. This allows references to remain constant even if objects are renamed.

For the standard CRUD (create, read, update, delete) operations, the mapping is slightly different:

CLI operation	Python API
<code>group list</code>	<code>group.get_all(engine)</code>
<code>group create</code>	<code>group.create(engine, group=</code>
<code>group "dexample" get</code>	<code>group.get(engine,</code>
<code>group "dexample" update</code>	<code>group.update(engine, , group=)</code>
<code>group "dexample" delete</code>	<code>group.delete(engine,</code>

### Example: creating a group

This is how you can create a group as a fully working example.

```
from delphixpy.web import groupfrom delphixpy.web.vo import Groupfrom
delphixpy.delphix_engine import DelphixEngineengine = DelphixEngine("delphix-address",
"delphix-user", "delphix-password", "DOMAIN")my_group = Group()my_group.name = "My
Group"my_group.description = "This is my new group!"group.create(engine, my_group)
```

## Asynchronous mode

The Python API runs by default in synchronous mode. If you would wish to perform operations asynchronously there is a context manager that allows you to do that. If you need to track job progress in asynchronous mode, you can get the reference of the last job started from `engine.last_job`. When exiting the async context manager, it will wait for all jobs started within the context to finish. You can also clear the job from the context so that you do not wait for its completion or status when exiting the context manager. If a job fails, `exceptions.JobError` will be thrown.

Here is how you would perform a sync operation on all databases asynchronously.

```
from delphixpy.delphix_engine import DelphixEngine
from delphixpy.web import database
engine = DelphixEngine("delphix-
address", "delphix-user", "delphix-password", "DOMAIN")
all_databases =
database.get_all(engine)
with job_context.asyncly(engine):
    for db in all_databases:
        database.sync(engine, db.reference)
```

## Python cookbook: adding a UNIX host

This topic describes the process of adding a UNIX host using the delphixpy Python API.

Within Delphix, there are both hosts and host environments. A host represents a remote system, but may or may not be a source or target for linking or provisioning. For example, in an Oracle RAC cluster, the cluster environment represents the location of the Oracle installation(s), and while there are hosts within that cluster they are not individually manageable as environments.

### Procedure

1. Create new environment creation parameters and initialize the structure for a UNIX host.  
ActionScript

```
from delphixpy.web.vo import HostEnvironmentCreateParameters,
    UnixHostEnvironment, UnixHostCreateParameters, UnixHost, EnvironmentUser,
    PasswordCredential
host_environment_create_parameters_vo =
    HostEnvironmentCreateParameters()
host_environment_create_parameters_vo.host_environment =
    UnixHostEnvironment()
host_environment_create_parameters_vo.host_parameters =
    UnixHostCreateParameters()
host_environment_create_parameters_vo.host_parameters.host =
    UnixHost()
host_environment_create_parameters_vo.primary_user =
    EnvironmentUser()
host_environment_create_parameters_vo.primary_user.credential =
    PasswordCredential()
```

2. Set the host address and port. The name of the environment is derived from the address used, though you can provide a more descriptive name if desired. The address can be a DNS names, IP addresses, or a comma separated list of the above.  
ActionScript

```
host_environment_create_parameters_vo.host_parameters.host.addresses =
    ["192.168.1.2"]
host_environment_create_parameters_vo.host_parameters.host.port =
    22
```

3. Set the toolkit path. This is where Delphix will store temporary binaries used while the host is configured as part of Delphix.  
ActionScript

```
host_environment_create_parameters_vo.host_parameters.host.toolkit_path =
    "/var/delphix"
```

4. Set the username and password to use when connecting over SSH. This user must have the privileges described in the Delphix Administration Guide. To configure a SSH user, change the credential object to `SystemKeyCredential`.

ActionScript

```
host_environment_create_parameters_vo.primary_user.name = "oracle"
host_environment_create_parameters_vo.primary_user.credential.password = "my secret password"
```

5. Commit the result. A reference to your new environment will be returned from the create call. The environment discovery process will execute as an asynchronous job. The default behavior is to wait for the result, so progress will be updated until the discovery process is complete or fails.  
ActionScript

```
from delphixpy.delphix_server import DelphixServer
from delphixpy.web import environment
server = DelphixServer("delphix-address", "delphix-user", "delphix-password", "DOMAIN")
new_environment_reference = environment.create(server, host_environment_create_parameters_vo)
```

6. Full example  
ActionScript

```
from delphixpy.delphix_server import DelphixServer
from delphixpy.web import environment
from delphixpy.web.vo import HostEnvironmentCreateParameters, UnixHostEnvironment, UnixHostCreateParameters, UnixHost, EnvironmentUser, PasswordCredential
host_environment_create_parameters_vo = HostEnvironmentCreateParameters()
host_environment_create_parameters_vo.host_environment = UnixHostEnvironment()
host_environment_create_parameters_vo.host_parameters = UnixHostCreateParameters()
host_environment_create_parameters_vo.host_parameters.host = UnixHost()
host_environment_create_parameters_vo.primary_user = EnvironmentUser()
host_environment_create_parameters_vo.primary_user.credential = PasswordCredential()
host_environment_create_parameters_vo.host_parameters.host.addresses = ["192.168.1.2"]
host_environment_create_parameters_vo.host_parameters.host.port = 22
host_environment_create_parameters_vo.host_parameters.host.toolkit_path = "/var/delphix"
host_environment_create_parameters_vo.primary_user.name = "oracle"
host_environment_create_parameters_vo.primary_user.credential.password = "my secret password"
server = DelphixServer("delphix-address", "delphix-user", "delphix-password", "DOMAIN")
new_environment_reference = environment.create(server, host_environment_create_parameters_vo)
```

## So you want to work with Delphix APIs?

What is RESTful? API? JSON? CLI? Object Reference? GET/POST? Cookies? HTTP/HTTPS? cURL? Where do I begin? Who can help me? Documentation? Tutorials? That's great for Linux, but I am on Windows? Parse? Don't have a clue about sed, awk, grep, cut, and other acronyms. What about Regular Expressions, like "Hello"?

Just a small sampling of questions that you may or may not know the answers to, let alone learning Delphix and a programming language. Delphix is a technical product, and being new to the Delphix family can be a bit overwhelming. The goal for this document is simple: to enable users to get up to speed quickly on how to use Delphix APIs.

This section covers the following topics:

- [Background information](#)
- [Delphix API reference URLs](#)
- [API prerequisite knowledge](#)
- [Delphix RESTful APIs command line basics](#)
- [API shell scripts programming language examples](#)
- [JSON parsing](#)
- [API use case commands and scripts](#)
- [API programming language examples](#)
- [API timeflows](#)

## Background information

This document assumes that you have some basic Delphix product experience and entry-level programming knowledge. The first two sections of this document, [Delphix API Reference URLs](#) and [API Prerequisite Knowledge](#), are focused on providing the required information and reference material/URLs.

This document is for informational and demonstration purposes only. The examples are for demonstration purposes only and must be used at your own risk. As always, test and verify on development systems prior to migrating code to production environments.

What is RESTful programming?

<http://stackoverflow.com/questions/671118/what-exactly-is-restful-programming>

 A great way to learn how to generate the Delphix RESTful API calls and the required JSON content is to use the Delphix CLI (Command Line Interface) and turn on the trace option.

```
Delphix5110HWv8> setopt trace=true
```

All subsequent CLI commands will display the GET or POST API URL with the respective input or output JSON data string. This guide will walk you through an example later.

## Delphix API reference URLs

There are a number of sources available to provide details, examples, and techniques for working with Delphix APIs. This section contains a small list of URLs that are worth reviewing/reading as required.

### CLI (command line interface)

The Delphix Engine provides a native command-line interface (CLI) accessible over SSH. This CLI provides an interactive layer on top of the public web service APIs, and is intended for users that wish to automate interactions with the Delphix Engine, or simply prefer a text-based interface. All of the functionality available in the CLI is also available through the public stable web service APIs should more full-featured automation be required. For more information on automation using CLI commands see [Command Line Interface Guide](#)

### RESTful APIs

#### **Must be logged in**

Users must be successfully logged in before /API pages can be accessed.

For more information on automation using the web service APIs, see the [Web Services API Guide](#).

API Documentation is also included within the Delphix Engine using the following formula:

`http://<delphix_engine>/api/`

For Example `http://172.16.160.195/api/`

For a complete list of Delphix APIs - JSON schema format, use the following URL:

`http://<delphix_engine>/api/json/delphix.json`

```

{
  "/delphix-about.json": {
    "cliVisibility": [
      "DOMAIN",
      "SYSTEM"
    ],
    "description": "Retrieve static system-wide properties.",
    "extends": {
      "$ref": "/delphix-typed-object.json"
    },
    "name": "PublicSystemInfo",
    "properties": {
      "apiVersion": {
        "$ref": "/delphix-version.json",
        "description": "Maximum supported API version of the current system software.",
        "type": "object"
      },
      "banner": {
        "description": "Security banner to display prior to login.",
        "type": "string"
      },
      "buildTimestamp": {
        "description": "Time at which the current system software was built.",
        "format": "date",
        "type": "string"
      },
      "buildTitle": {
        "description": "Description of the current system software.",
        "type": "string"
      },
      "buildVersion": {
        "$ref": "/delphix-version-info.json",
        "description": "Delphix version of the current system software.",
        "type": "object"
      },
      "configured": {
        "description": "Indicates whether the server has gone through initial setup or not.",
        "type": "boolean"
      },
      "currentLocale": {
        "description": "The current system locale.",
        "format": "locale",
        "type": "string"
      },
      "enabledFeatures": {
        "description": "The list of enabled features on this Delphix Engine.",
        "items": {
          "type": "string"
        },
        "type": "array"
      }
    }
  }
}

```

So, looking at the first JSON key/name:

```

"/delphix-about.json": {   "cliVisibility": [           "DOMAIN",           "SYSTEM"   ]
,   "description": "Retrieve static system-wide properties.",   . . .

```

And after logging into the Delphix Engine, translating this into the URL API for *about*:

<http://172.16.160.195/resources/json/delphix/about> will respond with the returned JSON data string.

```

{"type":"OKResult","status":"OK","result":{"type":"PublicSystemInfo","productType":"standard","productName":"Delphix Engine","buildTitle":"Delphix Engine 5.1.2.0","buildTimestamp":"2016-09-02T22:28:43.000Z","buildVersion":{"type":"VersionInfo","major":5,"minor":1,"micro":2,"patch":0},"configured":true,"enabledFeatures":["XPP","JETSTREAM"]}

```

```
, "apiVersion": {"type": "APIVersion", "major": 1, "minor": 8, "micro": 0}, "banner": null, "locales": ["en-US"], "currentLocale": "en-US", "job": null, "action": null}
```

For now, just remember that the Delphix Engine contains the API Documentation and Delphix JSON schema.

#### Masking APIs

Please refer to the Masking documentation at <https://maskingdocs.delphix.com> for information on the Masking APIs.

#### Cookbook examples

Delphix documentation includes a number of cookbook examples that will not be duplicated in this section but may be referenced.

[API Cookbook: Common Tasks, Workflows, and Examples](#)

There are also working examples provided within this document and are available for download.

## API prerequisite knowledge

### JSON

JSON (JavaScript Object Notation) is a minimal, readable format for structuring data. It is a simple format for transmitting data between applications, as an alternative to XML. The Delphix API uses JSON data structure in the format of strings to send and receive data from the API calls, as you will see later in the examples. First, let's look at the JSON fundamentals.

### Keys and values

The two primary parts that makeup JSON are keys and values. Together they make key/value pairs, also called name/value pairs.

- **Key** – Always a string enclosed in quotation marks.
- **Value** – Can be a string, number, boolean expression, array, or object.
- **Key/Value Pair** – Follows a specific syntax, with the key followed by a colon followed by the value. Key/value pairs are comma separated.

Let's take a JSON sample string and identify each part of the code.

```
{  "foo" : "bar",  "rows" : 100}
```

The curly brackets start and end the string. The key is "foo" and the value is "bar". A colon (:) is the delimiter between them. A comma (,) is the delimiter for multiple key/value pairs. The second pair is "rows" and the value is a number of 100.

### Types of values

Number	An integer or a decimal number
Boolean	True or false
String	Plain text alphanumeric readable characters
Null	Empty
Array	An associative array of values
Object	An associative array of key/value pairs

Numbers, booleans, and strings.

It is very important to understand the APIs JSON object definitions. Quoted values are treated as strings!

"x" : "1" is treated as a string, while

"x" : 1 is treated as a number

"y" : "true" is treated as a string, while

"y" : true is treated as a boolean true (false)

## Null values

```
{  "z" :  , "b" : "World"}
```

Nulls are empty values, but sometimes programmers code "" as a null value.

```
{  "z" : ""  , "b" : "World" }
```

**So always verify how the null values are defined and handled by the application.**

## Arrays

An array is indicated with the square brackets: [ value1, value2, etc. ]. In this example, we have added a categories key with an array of values.

```
..."foo" : {  "bar" : "Hello",  "category" : [ "greetings", "morals" ]}...
```

## Objects

An object is indicated by curly brackets: {"key", "value"}. Everything inside of the curly brackets is part of the object. We already learned that a value could be an object. Therefore, "foo" and the corresponding object are a key/value pair.

```
..."foo" : {  "bar" : "Hello" }...
```

The key/value pair "bar" : "Hello" is nested inside the key/value pair "foo" : { ... }. That is an example of a hierarchy (or nested data) within JSON data.

Arrays and Objects can be nested or contained within the same level.

## Summary

JSON arrays are [ , , ]

JSON nested objects are , , "x":{ "a":"1", "b":"2" }, ,

JSON data can be passed within the HTTP URL (file or argument), the header, or other handlers.

From within Shell Scripts or Programming Languages, JSON data is typically processed through a "JSON parser." This topic is covered later.

## Delphix CLI

Connecting to the Delphix engine CLI

Reference: [Connecting to the CLI](#)

There are two user roles accessible, the **sysadmin** and the **delphix\_admin**.

From a shell environment, you can connect using the ssh command. The IP Address (or Hostname) represents the Delphix Engine (case sensitive):

```
ssh sysadmin@127.16.160.195
```

```
ssh delphix_admin@127.16.160.195
```

From a putty session, open an ssh connection to the Delphix Engine IP Address or Hostname (case sensitive):

```
open 127.16.160.195
```

```
Login User: sysadmin@SYSTEM
```

```
#... or ...
```

```
Login User: delphix_admin@DOMAIN
```

After entering the correct password for the respective user, the menus for that user's role will be different. For example, the **sysadmin@SYSTEM** user has engine storage, whereas the **delphix\_admin@DOMAIN** user has database provisioning.

You can use the CLI for scripting and configure the connection for ssh passwordless connections.

[CLI Cookbook: Configuring Key-Based SSH Authentication for Automation](#)

How to use the CLI to learn the APIs

As stated earlier, a great way to learn how to generate the Delphix RESTful API calls and the required JSON content is to use the Delphix CLI (Command Line Interface) and turn on the `CLI> setopt trace=true` option.

Below is an example of how to get the JSON required parameters for a database refresh per the type of refresh performed.

Other types or options may require other JSON parameters, so after changing any parameter, we recommend performing an "ls" command to see if there are any new parameters and/or required values.

The refresh database example below shows how to use the CLI to identify reference objects **for** other CLI commands and the respective RESTful API structure when the `setopt trace=true` option is set.

```
$ ssh delphix_admin@172.16.160.195 Password: Delphix5030HWv8> ls
Childrenaboutaction...connectivitydatabaseenvironment... toolkituser
OperationsversionDelphix5030HWv8> database Delphix5030HWv8 database> ls
ObjectsNAME          PROVISIONCONTAINER    DESCRIPTIONDPXDEV01    -
Vdelphix_demo        delphix_demo          -delphix_demo         - Scripts               -
V_2C1                 Scripts                -Vvfiles               -                       -
Childrentemplate
OperationscreateEmptycreateRestorationDatasetexportfileMappinglinkoracleSupportedChar
acterSetsprovisionvalidateXppxpp
```

First, we need to identify the target Delphix virtualized database object to refresh ...

 Each Delphix object has a reference that is typically used for parameter values.

```
Delphix5030HWv8 database> select Vdelphix_demo Delphix5030HWv8 database
'Vdelphix_demo'> ls Properties      type: MSSqlDatabaseContainer    name:
Vdelphix_demo    creationTime: 2016-06-16T14:30:03.033Z    currentTimeflow:
```

```
'DB_PROVISION@2016-06-16T10:30:08' delphixManaged: true description:
(unset) group: Windows masked: false os: Windows performanceMode:
DISABLED processor: x86 provisionContainer: delphix_demo reference:
MSSQL_DB_CONTAINER-39 restoration: false runtime: type:
MSSqlDBContainerRuntime logSyncActive: false sourcingPolicy: type:
SourcingPolicy loadFromBackup: false logsyncEnabled: false transform
ation: false Operationsdelete...purgeLogsrefreshremoveLiveSource...Delphix5030HWv8
database 'Vdelphix_demo' refresh Delphix5030HWv8 database 'Vdelphix_demo' refresh *
> ls Properties type: RefreshParameters timeflowPointParameters: type:
TimeflowPointSemantic container: (required) location:
LATEST_POINTDelphix5030HWv8 database 'Vdelphix_demo' refresh * > set
timeflowPointParameters.container=delphix_demo Delphix5030HWv8 database
'Vdelphix_demo' refresh * > ls Properties type:
RefreshParameters timeflowPointParameters: type:
TimeflowPointSemantic container: delphix_demo (*) location:
LATEST_POINTDelphix5030HWv8 database 'Vdelphix_demo' refresh > *commit Dispatched
job JOB-100 DB_REFRESH job started for "Windows/Vdelphix_demo". Validating that
this dataset is managed by Delphix. Stopping virtual database. Unmounting
datasets. Unexporting storage containers. Metadata for dSource "Vdelphix_demo"
successfully deleted. Starting provisioning of virtual database "Vdelphix_demo".
Creating new TimeFlow. Generating recovery scripts. Mounting
datasets. Mounting read-only source logs dataset. Running user-specified pre-
provisioning script. Recovering virtual database. The virtual database recovery
was successful. Unmounting read-only source logs dataset. Running user-
specified post-provisioning script. The virtual database "Vdelphix_demo" was
successfully provisioned. DB_REFRESH job for "Windows/Vdelphix_demo" completed
successfully.
```

Refresh again but this time turn on the `setopt trace=true` option.

```
Delphix5030HWv8 database 'Vdelphix_demo' refreshDelphix5030HWv8 database
'Vdelphix_demo' refresh * > lsProperties type:
RefreshParameters timeflowPointParameters: type:
TimeflowPointSemantic container: (required) location:
LATEST_POINTDelphix5030HWv8 database 'Vdelphix_demo' refresh * > set
timeflowPointParameters.container=delphix_demoDelphix5030HWv8 database
'Vdelphix_demo' refresh * > lsProperties type:
RefreshParameters timeflowPointParameters: type:
TimeflowPointSemantic container: delphix_demo location:
LATEST_POINTDelphix5030HWv8 database 'Vdelphix_demo' refresh * > setopt
trace=trueDelphix5030HWv8 database 'Vdelphix_demo' refresh * > commit=== POST /
resources/json/delphix/database/MSSQL_DB_CONTAINER-39/refresh ==={ "type":
"RefreshParameters", "timeflowPointParameters": { "type":
"TimeflowPointSemantic", "container": "MSSQL_DB_CONTAINER-38" }}...
```

 The "container" value in the JSON output above is different from the target VDB reference because we are refreshing from the source database container! In this example, the `setopt timeflowPointParameters.container=delphix_demo` is represented in JSON output as `"container": "MSSQL_DB_CONTAINER-38"`

Using the CLI, you can identify the RESTful API POST and GET commands along with the JSON input data requirements.

```
=== POST /resources/json/delphix/database/MSSQL_DB_CONTAINER-39/refresh ==={      "type": "RefreshParameters",      "timeflowPointParameters": {          "type": "TimeflowPointSemantic",          "container": "MSSQL_DB_CONTAINER-38"      } }
```

So framing the RESTful URL for a virtual database refresh, the URL will look like

**http://<delphix\_engine>/resources/json/delphix/database/ MSSQL\_DB\_CONTAINER-39 /refresh**

where the **MSSQL\_DB\_CONTAINER-39** represents the target virtualized database to refresh. We need to POST the JSON data to the URL for processing.

```
{      "type": "RefreshParameters",      "timeflowPointParameters": {          "type": "TimeflowPointSemantic",          "container": "MSSQL_DB_CONTAINER-38"      } }
```

The **"timeflowPointParameters"** key has 6 **"type": "..."** options, each of which has its own set of parameters. The type **"TimeflowPointSemantic"** uses the default LATEST\_POINT within the source container, so for simplicity, we will use this type. For more information on timeflowPointParameters 6 types, see the Advanced Section.

**If this is a little confusing at this point, do not worry, that's typical.** Complete examples will be shown later. The important items to remember are:

- Delphix often uses object reference names within the JSON data.
- Using the `setopt trace=true` the option provides the construct for the RESTful API URLs and the JSON data for POST / GET operations.

## HTTP

We use the HTTP protocol every day for web browsing and commercial business. From finding a new restaurant to buying a 1986 Ford Thunderbird Turbo Coupe!

Most people see the HTTP within the URL Address field within the Web Browser window – for example, <http://www.google.com>

But behind the scenes, HTTP is performing a wide range of functionality. For RESTful APIs, they use HTTP's GET and POST form functionality to process data. In Delphix's case, the data is also represented as JSON structures.

HTTP GET operation is used to return data only, while HTTP POST operation is used to provide data input in the form of a structured JSON data string or file.

## cURL

What is cURL?

The **cURL** client command is based on a library supporting a number of web protocols, including HTTP. The "curl" command can be called from the command line, while the cURL library is commonly integrated with your favorite programming languages, such as Java, JSP, Python, Perl, PHP, .NET, and PowerShell.

Due to its widespread adoption, we will use cURL for making the Delphix RESTful API calls within this document. Some operating systems or languages support their own HTTP commands / related libraries, and you can use these instead of cURL. One alternative is the "wget" command described later.

Is cURL installed?

```
Operating System Prompt> curl --versioncurl 7.19.7 (x86_64-redhat-linux-gnu)
libcurl/7.19.7 NSS/3.19.1 Basic ECC zlib/1.2.3 libidn/1.18 libssh2/1.4.2Protocols:
tftp ftp telnet dict ldap ldaps http file https ftps scp sftp Features: GSS-Negotiate
IDN IPv6 Largefile NTLM SSL libz
```

Get the HTTP output from [google.com](http://google.com)

```
Operating System Prompt> curl www.google.com
```

Wget

An alternative to cURL is Wget, which is typically a native command on all Linux environments. See the Appendix for a complete comparison between Wget and cURL.

dxtoolkit2

Delphix has developed a very robust toolkit, dxtoolkit2, which utilizes the Delphix RESTful APIs. This toolkit is cross-platform. Its commands are built with the Perl programming language.

We recommend that you review the dxtoolkit2 documentation; you may find a utility that already performs your desired function. For example, the utility ***dx\_get\_analytics*** is absolutely great for dumping analytic data from the Delphix Engine into a .csv (comma-separated value) format, which you can then easily integrate into your enterprise monitoring tools. See the sample "Analytics" use case.

Contact Delphix personnel for the latest download.

## Delphix RESTful APIs command line basics

### Authentication

RESTful APIs require authentication. Just plugging the URL into a web browser or running an operating system cURL command will return an authentication/login required error message.

### Command line:

```
curl http://172.16.160.195/resources/json/delphix/environment
```

### Response:

```
<!DOCTYPE html><html><head><title>Apache Tomcat/8.0.29 - Error report</title><style
type="text/css">H1 {font-family:Tahoma,Arial,sans-serif;color:white;background-
color:#525D76;font-size:22px;} H2 {font-family:Tahoma,Arial,sans-
serif;color:white;background-color:#525D76;font-size:16px;} H3 {font-
family:Tahoma,Arial,sans-serif;color:white;background-color:#525D76;font-size:14px;}
BODY {font-family:Tahoma,Arial,sans-serif;color:black;background-color:white;} B
{font-family:Tahoma,Arial,sans-serif;color:white;background-color:#525D76;} P {font-
family:Tahoma,Arial,sans-serif;background:white;color:black;font-size:12px;}A
{color : black;}A.name {color : black;}.line {height: 1px; background-color: #525D76;
border: none;}</style> </head><body><h1>HTTP Status 403 - Use /resources/json/
delphix/login to log in first</h1><div class="line"></div><p><b>type</b> Status
report</p><p><b>message</b> <u>Use /resources/json/delphix/login to log in first</
u></p><p><b>description</b> <u>Access to the specified resource has been forbidden.</
u></p><hr class="line"><h3>Apache Tomcat/8.0.29</h3></body></html>
```

The authentication process requires you to establish a session first.

The example within this section illustrates the session/login and subsequent API calls with cURL using cookies created when the session was established.

### Session

#### API Version Information

When programming for compatibility, the API version number is very important. Please be aware of the differences between versions for enterprise applications. For example, if you specify a 1.11.6 version, ONLY the available calls and functionality for that version will be used, and it will only be operational on Delphix Engine versions that support that version.

The session uses the `-c` for the cookie creation, the login uses the `-b` for the exiting cookie created by the session, and `-c` to create a new cookie, the other commands use the `-b` for using the existing cookie created by the login.

From the Unix/Linux command line

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/session \
-c ~/cookies.txt -H "Content-Type: application/json" <<EOF{  "type": "APISession",
"version": {      "type": "APIVersion",      "major": 1,      "minor": 11,
"micro": 6    }}EOF
```

Returned to the command line are the results (added linefeeds for readability)

```
{  "status":"OK",  "result": {      "type":"APISession",      "version": {
"type": "APIVersion",      "major": 1,      "minor": 11,      "micro":
6      },      "locale": "en_US",      "client": null  },  "job": null}
```

Login

Once you have established the session, the next step is to authenticate to the server by executing the Login Request API. Unauthenticated sessions are prohibited from making any API calls other than this login request. The username can be either a system user or domain user; the backend will authenticate using the appropriate method.

The session uses the `-c` for the cookie creation, the login uses the `-b` for the exiting cookie created by the session, and `-c` to create a new cookie, the other commands use the `-b` for using the existing cookie created by the login.

From the Unix/Linux command line

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/login \
-b ~/cookies.txt -c ~/cookies.txt -H "Content-Type: application/json"
<<EOF{  "type": "LoginRequest",  "username": "delphix_username",  "password":
"delphix_password"}EOF
```

Returned to the command line are the results (added linefeeds for readability)

```
{"status":"OK","result":"USER-2","job":null,"action":null}
```

Sample Delphix API call

With a successful authentication (session, login, and saved cookie), calls to the Delphix Engine can now be made to perform the desired functionality.

The session uses the `-c` for the cookie creation, the login uses the `-b` for the exiting cookie created by the session, and `-c` to create a new cookie, the other commands use the `-b` for using the existing cookie created by the login.

For starters, let's create a session, login, and get the existing environments defined within the Delphix Engine.

```
curl -s -X POST -k --data @- http://172.16.160.195/resources/json/delphix/session \-c
~/cookies.txt -H "Content-Type: application/json" <<EOF{  "type":
"APISession",    "version": {          "type": "APIVersion",    "major":
1,              "minor": 7,          "micro": 0    }}EOF
```

```
curl -s -X POST -k --data @- http://172.16.160.195/resources/json/delphix/login
\  -b ~/cookies.txt -c ~/cookies.txt -H "Content-Type: application/json"
<<EOF{  "type": "LoginRequest",    "username": "admin",    "password": "delphix"}
EOF
```

```
curl -X GET -k http://172.16.160.195/resources/json/delphix/environment \  -b ~/
cookies.txt -H "Content-Type: application/json"
```

Returned to the command line are the results (added linefeeds for readability)

```
{"type":"ListResult","status":"OK","result":[ {"type":"WindowsHostEnvironment",
"reference":"WINDOWS_HOST_ENVIRONMENT1", "namespace":null, "name":"Window Target",
"description":"", "primaryUser":"HOST_USER-1", "enabled":false, "host":"WINDOWS_HO
ST1", "proxy":null }, { "type":"UnixHostEnvironment", "reference":"UNIX_HOST_ENVIR
ONMENT-3", "namespace":null, "name":"Oracle Target", "description":"",
"primaryUser":"HOST_USER-3", "enabled":true, "host":"UNIX_HOST-3","aseHostEnvironme
ntParameters":null }],"job":null,"action":null,"total":2,"overflow":false}
```

#### Windows PowerShell authentication example

See the PowerShell section below if cURL is not yet available on your operating system.

These commands work on Windows Command Prompt with the respective JSON files: session.json and login.json

Filename: session.json

```
{  "type": "APISession",    "version": {          "type": "APIVersion",    "major
": 1,              "minor": 7,          "micro": 0    }}
```

Filename: login.json

```
{"type": "LoginRequest","username": "admin","password": "delphix"}
```

(In Powershell you use curl.exe or modify the default alias)...

```
curl.exe --insecure -c cookies.txt -sX POST -H "Content-Type: application/json" -d
"@session.json" http://172.16.160.195/resources/json/delphix/sessioncurl.exe --
insecure -b cookies.txt -c cookies.txt -sX POST -H "Content-Type: application/json"
-d "@login.json" http://172.16.160.195/resources/json/delphix/logincurl.exe --
insecure -b cookies.txt -sX GET -H "Content-Type: application/json" -k http://
172.16.160.195/resources/json/delphix/system
```

Putting the above commands within a Powershell script:

**Filename: auth1.ps1**

```
<#Filename: auth.ps1Description: Delphix Powershell Sample Authentication
Script ...Date: 2016-08-02Author: Bitt...#>
```

## API shell scripts programming language examples

### Why use shell scripts?

Shell scripts are great tools for rapid development and validation for simple (smaller) requirements. Most development is done iteratively, and shell scripts provide immediate feedback on logic and code.

### **Company-supported programming languages are the preferred tools for enterprise applications.**

Most likely, your company employs more Java and/or PHP programmers than Linux Shell script programmers.

The "use cases" will be programmed using either Unix/Linux Shell and/or Windows PowerShell scripts. You can easily port the logic from these scripts into your favorite programming language. Basic examples of connection with API will be provided for a number of major programming languages in a later section of this document.

### Linux/Unix/(and Mac too) shell scripts

There are numerous shell environments, including sh, bash, csh, ksh, and tsh. Identify the current shell environment using any of the commands below:

```
ps -p $$
ps -p $$ -ocomm=
echo $0
ps -ef | grep $$ | grep -v grep
ps -ef | egrep "^\s*\d+\s+$$\s+"
```

The examples provided have all been run from the bash shell environment and may or may not run the same as the other shells. We recommend that you start a bash shell by typing **bash** at the operating system prompt, like this:

```
Operating_System_Prompt> bash
```

The scripts included within this document have all been run on Linux and Mac environments within a bash shell and are NOT certified by any means. As always, test and verify in development for your environment.

For non-Linux platforms and non-bash shell environments, please re-validate for your configuration and search the web for any alternative methods/tools/utilities that may perform the same actions.

### Windows PowerShell

Powershell Open Source is now available for Linux and Mac OS. for more information refer to [Microsoft Open Source](#)

### Requirements

Windows has a number of versions of Powershell. The minimum version for Delphix is 2.0 for SQL Server 2008 environments. There are numerous enhancements and features with subsequent Powershell versions. Additionally, you must be aware of the architecture of 32bit or 64bit Powershell versions you are running from within.

```
PS> $PSVersionTable.PSVersion
```

```
Major Minor Build Revision
```

```
-----
```

```
2 0 -1 -1
```

### 32bit or 64 bit

If executing Powershell scripts from within Delphix Pre/Post Scripts commands or Delphix hooks, the default Powershell used is 32 bit, whereas the typical default Windows Powershell is 64 bit. However, Powershell allows you to execute 64 bit Powershell command from within the 32 bit environment. Shown below is a simple alias, ps64, to execute 64bit Powershell scripts.

```
PS> set-alias
```

```
ps64 "$env:windir\sysnative\WindowsPowerShell\v1.0\powershell.exe"
```

Sample call to execute 64bit Powershell script

```
PS> ps64 [path\to\any_64bit_powershell_script].ps1
```

Courtesy of this article: <http://www.gregorystrike.com/2011/01/27/how-to-tell-if-powershell-is-32-bit-or-64-bit/>

```
PS> if ($env:Processor_Architecture -eq "x86") { write "running on 32bit" }
else {write "running on 64bit"}
running on 32bit
```

...or...

```
PS> if ([System.IntPtr]::Size -eq 4) { "32-bit" } else { "64-bit" }
32-bit
```

It is worth noting that the locations of the 32-bit and 64-bit versions of Powershell are somewhat misleading. The 32-bit PowerShell is found at C:\Windows\SysWOW64\WindowsPowerShell\v1.0\powershell.exe

and the 64-bit PowerShell is at C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe

Execution of scripts security disabled

It is possible to disable Powershell environments on the system. If they are disabled, you will see the following error for any Powershell script that you try to execute.

```

PS> . .
[any_powershell_script].ps1
File [any_powershell_script].ps1 cannot be loaded because the execution of
scripts is disabled on this system. Please see "get-help about signing" for
more details.
At line:1 char:2
+ . <<<< .\ [any_powershell_script].ps1
+ CategoryInfo          : NotSpecified: ( [], PSSecurityException
+ FullyQualifiedErrorId : RuntimeException

```

To enable Powershell scripts to be executed, set the execution policy to Yes.

```

PS> set-executionpolicy remotesigned
Execution Policy Change
The execution policy helps protect you from scripts that you do not trust.
Changing the execution policy might expose you to the security risks
described in the about_Execution_Policies help topic. Do you want to change
the execution policy?
[Y] Yes [N] No [S] Suspend [?] Help (default is "Y"): Y
PS>

```

Now your Powershell scripts will be executed.

curl.exe

Not all Windows platforms have the cURL executable installed, the easiest way to install and use cURL on Windows is as follows:

1. Download the package from <https://curl.se/windows/> and unzip.
2. In the "bin" folder find "curl.exe" and move it to "C:\Windows\System32".

Then you will be able to use the curl command from the Windows Command Prompt or PowerShell console.

```

PS> curl.exe --version
curl 7.49.1 (x86_64-w64-mingw32) libcurl/7.49.1 OpenSSL/1.0.2h zlib/1.2.8
libidn/1.32 libssh2/1.7.0 nghttp2/1.12.0 librtmp/2.3
Protocols: dict file ftp ftps gopher http https imap imaps ldap ldaps pop3
pop3s rtmp rtsp scp sftp smtp smtps telnet tftp
Features: IDN IPv6 Largefile SSPI Kerberos SPNEGO NTLM SSL libz TLS-SRP HTTP2
Metalink

```

Invoking the curl or curl.exe from Powershell command line.

```
PS> Get-Command curl

CommandType Name ModuleName
-----
Alias curl -> Invoke-WebRequest
```

```
PS> Get-Command curl.exe

CommandType Name ModuleName
-----
Application curl.exe
```

If the alias curl name is to the Invoke-WebRequest, you will need to use the curl.exe command explicitly or remove the alias.

```
PS> Remove-item alias:curl
```

Verify that curl and/or curl.exe work from the respective Powershell environment:

```
PS> curl.exe --version
curl 7.49.1 (x86_64-w64-mingw32) ...

PS> curl --version
curl 7.49.1 (x86_64-w64-mingw32) ...
```

## JSON parsing

### Unix/Linux/Mac shell

Unix/Linux tools come natively with a host of shell utilities that one can use for parsing out the desired name/value pairs. Tools include sed, awk, cut, tr, and grep, to name a few. System administrators use these utilities frequently and may be able to assist with the methods for parsing JSON strings. For more information please refer to [Parsing JSON with UNIX tools](#) and [Extract a JSON value from a BASH script](#)

### Basic awk and sed parsing

```
json='{ "type": "OKResult", "status": "OK", "result":
{ "type": "Job", "reference": "JOB-53", "namespace": null, "name": null, "actionType": "DB_SYNC
", "target": "ORACLE_DB_CONTAINER-9", "targetObjectType": "OracleDatabaseContainer", "jobS
tate": "RUNNING", "startTime": "2016-08-12T19:58:59.811Z", "updateTime": "2016-08-12T19:58
:59.828Z", "suspendable": true, "cancelable": true, "queued": false, "user": "USER-2", "emailA
ddresses": null, "title": "Run SnapSync for database
\ "VDPXDEV1\ ".", "percentComplete": 0.0, "targetName": "Oracle_Source/VDPXDEV1", "events":
[ { "type": "JobEvent", "timestamp": "2016-08-12T19:58:59.840Z", "state": null, "percentCompl
ete": 0.0, "messageCode": "event.job.started", "messageDetails": "DB_SYNC job started for
\ "Oracle_Source/
VDPXDEV1\ ".", "messageAction": null, "messageCommandOutput": null, "diagnoses":
[ ], "eventType": "INFO" } ], "parentActionState": "WAITING", "parentAction": "ACTION-238"}, "j
ob": null, "action": null }' echo $json | sed -e 's/[{}]/'/g' | awk -v RS=',' -F:
' { print $1 $2 } ' type "OKResult" status "OK" result "type" reference "JOB-53" namespac
e "null" name "null" actionType "DB_SYNC" target "ORACLE_DB_CONTAINER-9"
targetObjectType "OracleDatabaseContainer" jobState "RUNNING" startTime
"2016-08-12T19" updateTime "2016-08-12T19" suspendable "true" cancelable "true" queued
false user "USER-2" emailAddresses "null" title "Run SnapSync for database
\ "VDPXDEV1\ ". "percentComplete" 0.0 targetName "Oracle_Source/VDPXDEV1" events [ "type"
timestamp "2016-08-12T19" state null percentComplete 0.0 messageCode "
event.job.started" messageDetails "DB_SYNC job started for \ "Oracle_Source/
VDPXDEV1\ ". "messageAction" null messageCommandOutput "null" diagnoses [ ] eventType
"INFO" parentActionState "WAITING" parentAction "ACTION-238" job "null" action "null
```

Find jobState. Print the second argument, and remove the double-quotes.

```
echo $json | sed -e 's/[{}]/'/g' | sed s/\\"//g | awk -v RS=',' -F: '$1=="jobState"{p
rint $2}' RUNNING
```

The first sed removed the brackets and braces. The second sed removes the double-quotes. The awk command parses the line by comma delimiters and then parses each line by the semi-colon delimiter and if the first variable \$1 is equal to the **jobState** value then print the second \$2 variable.

If the results contain an array of values, then you need to loop through each set and parse out the desired value. For example,

```
json='{ "type": "ListResult", "status": "OK", "result":
[ { "type": "WindowsHostEnvironment", "reference": "WINDOWS_HOST_ENVIRONMENT-1", "namespace
": null, "name": "Window
Target", "description": "", "primaryUser": "HOST_USER-1", "enabled": false, "host": "WINDOWS_
```

```
HOST-1", "proxy": null},
{"type": "UnixHostEnvironment", "reference": "UNIX_HOST_ENVIRONMENT-3", "namespace": null,
"name": "Oracle
Target", "description": "", "primaryUser": "HOST_USER-3", "enabled": true, "host": "UNIX_HOST
-3", "aseHostEnvironmentParameters": null}], "job": null, "action": null, "total": 2, "overflow":
false}'
```

Parse out array object into separate lines

```
SOURCE_ENV="Oracle Target"lines=`echo ${json} | cut -d "[" -f2 | cut -d "]" -f1 | awk
-v RS='},{}' -F: '{print $0}' `while read -r linedo #echo "Processing $line" #e
cho $line | sed -e 's/[{}]/''/g' | sed s/\\"//g | awk -v RS=',' -F: '$1=="name"{print
$2}' TMPNAME=`echo $line | sed -e 's/[{}]/''/g' | sed s/\\"//g | awk -v RS=',' -F:
'$1=="name"{print $2}' ` #echo "Name: |${TMPNAME}| |${SOURCE_ENV}|" if [[ "$
{TMPNAME}" == "${SOURCE_ENV}" ]] then echo $line | sed -e 's/[{}]/''/g' |
sed s/\\"//g | awk -v RS=',' -F: '$1=="primaryUser"{print $2}' PRI_USER=`echo
$line | sed -e 's/[{}]/''/g' | sed s/\\"//g | awk -v RS=',' -F: '$1=="primaryUser"{pri
nt $2}' ` break fidone <<< "$(echo -e "$lines)" echo "primaryUser
reference: ${PRI_USER}"
```

Output:

```
primaryUser reference: HOST_USER-3
```

The above methods will be used within the sample scripts since they use the native Linux tools. They typically do not require you to load extra packages or libraries onto the system.

There are a number of open-source utilities designed to simplify the parsing of JSON, such as *jsawk* and *jq*.

### jsawk

Linux:

- [jsawk](#)

Mac:

- [jsawk on MAC](#)

### jq

Reference- <https://stedolan.github.io/jq/>

64-bit system:

- `wget https://github.com/stedolan/jq/releases/download/jq-1.6/jq-linux64`
- `chmod +x ./jq`
- `sudo cp jq /usr/local/bin`

Older versions:

- Reference- <https://stedolan.github.io/jq/download/>

Another method is to use an existing programming language typically available with your native operating systems, such as Perl or Python.

```
$ which perl/usr/bin/perl$ which python/usr/bin/python
```

Example: Use Python to pretty format the JSON data string.

Pretty JSON using Python ...

```
json='{ "type": "OKResult", "status": "OK", "result":
{ "type": "SystemInfo", "productType": "standard", "productName": "Delphix
Engine", "buildTitle": "Delphix Engine
5.1.1.0", "buildTimestamp": "20160721T07:23:41.000Z", "buildVersion":
{ "type": "VersionInfo", "major": 5, "minor": 1, "micro": 1, "patch": 0}, "configured": true, "ena
bedFeatures": [ "XPP", "MSSQLHOOKS" ], "apiVersion":

}
```

jq parser

The "jq" command line parser is available on Unix, Linux, Mac, and Windows platforms. Typically, for Windows, the built-in ConvertFrom/To-Json object parser will be used. "jq" is being included in most native Linux distributions and is easy to install on the Mac OS.

## References:

[Parsing JSON with jq](#)[Installation FAQ](#)[Mac Installation](#)

## Example:

```

json='{ "type": "ListResult", "status": "OK", "result":
  [{"type": "OracleLinkedSource", "reference": "ORACLE_LINKED_SOURCE-52", "namespace": null, "name": "DPXDEV01", "description": null, "virtual": false, "restoration": false, "staging": false, "container": "ORACLE_DB_CONTAINER-120", "config": "ORACLE_SINGLE_CONFIG-40", "status": "DEFAULT", "runtime":
    {"type": "OracleSourceRuntime", "status": "RUNNING", "accessible": true, "databaseSize": 2.409529344E9, "notAccessibleReason": null, "databaseMode": "READ_WRITE", "lastNonLoggedLocation": "0", "activeInstances":
      [{"type": "OracleActiveInstance", "instanceNumber": 1, "instanceName": "DPXDEV01", "hostName": "linuxtarget.delphix.local"}], "databaseStats": null, "bctEnabled": true, "racEnabled": null, "dnfsEnabled": false, "archiveLogEnabled": null}, "backupLevelEnabled": false, "rmanChannels": 2, "filesPerSet": 5, "checkLogical": false, "externalFilePath": null, "encryptedLinkingEnabled": false, "compressedLinkingEnabled": true, "bandwidthLimit": 0, "numberOfConnections": 1, "enabled": true, "preScript": "", "postScript": "", "role": "PRIMARY"}, {"type": "OracleVirtualSource", "reference": "ORACLE_VIRTUAL_SOURCE-25", "namespace": null, "name": "VBITT", "description": null, "virtual": true, "restoration": false, "staging": false, "container": "ORACLE_DB_CONTAINER-121", "config": "ORACLE_SINGLE_CONFIG-47", "status": "DEFAULT", "runtime":

```

We have a very big JSON string above. Let's perform some basic jq parsing.

1. Pipe JSON string into jq command line parser.

```

ActionScript

echo $json | jq '.'

```

2. The output is a pretty human-readable JSON formatted string.

3. Get the first-level status value (...,"status":"OK",...)

```
ActionScript
echo $json | jq '.status'"OK"
```

4. Get raw values (not quoted).

```
ActionScript
echo $json | jq --raw-output '.status'OK
```

5. Get a number of rows returned for the type equal to "ListResult" API returned request.

```
ActionScript
echo $json | jq --raw-output '.total'2
```

6. Get the first result set.

```
ActionScript

echo $json | jq '.result[0] '{
  "type": "OracleLinkedSource", "reference":
"ORACLE_LINKED_SOURCE-52", "namespace": null, "name": "DPXDEV01", "des
cription": null, "virtual": false, "restoration": false, "staging":
false, "container": "ORACLE_DB_CONTAINER-120", "config":
"ORACLE_SINGLE_CONFIG-40", "status": "DEFAULT", "runtime": {
  "type": "OracleSourceRuntime", "status": "RUNNING", "accessible": true,
  "databaseSize": 2409529344, "notAccessibleReason": null,
  "databaseMode": "READ_WRITE", "lastNonLoggedLocation": "0", "activ
eInstances": [
    {
      "type": "OracleActiveInstance",
      "instanceNumber": 1,
      "instanceName": "DPXDEV01",
      "hostName": "linuxtarget.delphix.local"
    }
  ],
  "databaseStats": null, "bctEnabled": true, "racEnabled": null,
  "dnfsEnabled": false, "archivelogEnabled": null }, "backupL
evelEnabled": false, "rmanChannels": 2, "filesPerSet": 5, "checkLogica
l": false, "externalFilePath": null, "encryptedLinkingEnabled": false,
"compressedLinkingEnabled": true, "bandwidthLimit": 0, "numberOfConnecti
ons": 1, "enabled": true, "preScript": "", "postScript": "", "role":
"PRIMARY"}'
```

7. Get the first result set name value.

```
ActionScript
echo $json | jq --raw-output '.result[0].name'DPXDEV01
```

8. Get first result set reference value.

```
ActionScript
echo $json | jq --raw-output '.result[0].reference'
```

9. Get first result set name=value pairs.

```
ActionScript
echo $json | jq '.result[0]' | jq -r "to_entries|map(\"(.key)=(.value|tostring)
\").[]" | grep container container=ORACLE_DB_CONTAINER-120
```

10. Get ALL result sets name values.

```
ActionScript
echo $json | jq '.result[].name'"DPXDEV01"'VBITT"
```

11. Get ALL result sets "reference" and "container" values.

```
ActionScript
echo $json | jq '.result[].reference,.result[].container'"ORACLE_LINKED_SOURCE-
52'"ORACLE_VIRTUAL_SOURCE-25'"ORACLE_DB_CONTAINER-120'"ORACLE_DB_CONTAINER-121"
```

12. Now, let's scan ALL result sets for a conditional match and return a related value.

```
echo $json | jq --raw-output '.result[] | select(.name=="VBITT") | .container'
ORACLE_DB_CONTAINER-121echo $json | jq --raw-output '.result[] |
select(.name=="VBITT") | .reference' ORACLE_VIRTUAL_SOURCE-25echo $json | jq --raw-
output '.result[] | select(.name=="VBITT")
| .container, .reference'ORACLE_DB_CONTAINER-121ORACLE_VIRTUAL_SOURCE-25
```

This is the typical usage for Delphix, where the human-readable name is provided and we need to look up the object reference, container, status, etc. for the respective name. Some object references are based on expressions such as "and" or "or" conditions.

```
echo $json | jq --raw-output '.result[] |
select(.environment=="UNIX_HOST_ENVIRONMENT-9" and .name=="/u02/ora/app/product/
11.2.0/dbhome_1" ) | .reference '
```

In this case, the jq select command has an "and" condition in order to correctly identify the target result object index. This is important for getting the correct and single return value for `| .reference`, since there might be more than one instance within the environment.

For a working example of using the jq JSON parser, see the VDB Init using jq command-line JSON Parser use case, **Filename: vdb\_init.sh**. A version of all the Unix/Linux/Mac shell scripts exists within the code provided. It contains the **\*\_jq.sh** within the filename.

## PowerShell

Starting with Powershell 3.0, there are ConvertFrom-Json and ConvertTo-Json modules/commands to parse the JSON string data to/from objects. If you are stuck with Powershell 2.x., the next section provides similar functions as a method of working with JSON strings.

 These 2.x functions are not 100% the same as the Powershell 3.0 ConvertFrom-Json/ConvertTo-Json modules.

## PowerShell 2 example

Filename: *parse\_2.0.ps1*

For Powershell 2.0, there are no JSON-provided functions or commands, so the following will serialize the JSON data to a serialized array.

```
function ConvertTo-Json20([object] $item){    add-type -assembly
system.web.extensions $ps_js=new-object
system.web.script.serialization.javascriptSerializer    return
$ps_js.Serialize($item)}function ConvertFrom-Json20([object] $item){    add-type
-assembly system.web.extensions $ps_js=new-object
system.web.script.serialization.javascriptSerializer    # The comma operator is the
array construction operator in PowerShell    return ,$ps_js.DeserializeObject($item)}
```

Use the JSON from the system API Call.

```
$json='{"type":"OKResult","status":"OK","result":
{"type":"SystemInfo","productType":"standard","productName":"Delphix
Engine","buildTitle":"Delphix Engine
5.1.1.0","buildTimestamp":"20160721T07:23:41.000Z","buildVersion":

```

### PowerShell 3 or greater example

Starting with Powershell 3.0, there are `ConvertFrom-Json` and `ConvertTo-Json` commands to parse the JSON data to/from objects.

Reference:

- [ConvertFrom-Json](#)
- [ConvertTo-Json](#)

```
$o = $json | ConvertFrom-Json
```

There are a number of tutorials and functional examples on the web. Below is an excerpt from the [PowerShell introduction video for Linux / Mac Open Source announcement](#).

PowerShell JSON `ConvertTo-Json` and Python Example 15:55 through 21:16

The concept is straightforward:

- The `ConvertFrom-Json` JSON string is converted into a Powershell object that you can reference directly.
- The `ConvertTo-Json` takes the JSON object and converts it to a string.

### JSON parsing from within programming languages

Most programming languages provide their own libraries, functions, and methods for parsing JSON data strings into objects/hashtables/arrays/xml that the native programming language can easily process.

## API use case commands and scripts

### Sample script parsers

The Delphix Use Cases scripts provided use the native operating system "curl" command and then a JSON parser, depending on the engine on which you are running the scripts.

For Unix/Linux/Mac, the scripts provided use both native shell commands and/or the jq parser program commands. Subroutines have been provided for both methods:

```
Native Shell commands:      parseJSON_subroutines.sh
jq Parser commands:        jqJSON_subroutines.sh
```

For Windows, the scripts are for Powershell 2.0 and utilize the custom `ConvertFrom-Json20` and `ConvertTo-Json20` functions provided. As noted, with Powershell 3.0, there are `ConvertFrom-Json` and `ConvertTo-Json` command-lets provided by Powershell.

### Using the jq parser

These are some of the jq commands used within the scripts. The first is a shell script subroutine which is used for finding and returning a single item value.

#### Filename: jqJSON\_subroutines.sh

#### Subroutines

This code requires the jq Linux/Mac JSON parser program

```
jqParse() {
  STR=$1                # json string
  FND=$2                # name to find
  RESULTS=""           # returned name value
  RESULTS=`echo $STR | jq --raw-output '."'$FND'`
  #echo "Results: ${RESULTS}"
  if [ "${FND}" == "status" ] && [ "${RESULTS}" != "OK" ]
  then
    echo "Error: Invalid Satus, please check code ... ${STR}"
    exit 1;
  elif [ "${RESULTS}" == "" ]
  then
    echo "Error: No Results ${FND}, please check code ... ${STR}"
    exit 1;
  fi
  echo "${RESULTS}"
}
```

The subroutine is called from the shell script to return values based on the key (or name) value provided.

Usage – After every curl command, check that the returned status value is "OK".

```
RESULTS=$( jqParse "${STATUS}" "status" )
```

Call the jqParse subroutine, where

- \${STATUS} is the returned JSON string from the curl command, and
- the value we want returned is where the name/key is equal to "status"

Usage – Get a single value within the returned nested result object:

```
JOBSTATE=$( jqParse "${JOB_STATUS}" "result.jobState" )
```

Call the jqParse subroutine, where

- \${JOB\_STATUS} is the returned JSON string from the cURL command, and
- the value we want returned is where the name/key is equal to "jobState" with the nested ".result" object.

Usage – Find name/value result object and return another value within the select result object:

Use jq to parse out container reference for name of \$SOURCE\_SID ...

```
CONTAINER_REFERENCE=`echo ${STATUS} | jq --raw-output '.result[] | select(.name=="${SOURCE_SID}") | .reference '`
```

where

- \${STATUS} is the returned JSON string from the cURL command, and
- the value we want returned is based on the selected nested result object where the .result[].name is equal to "\${SOURCE\_SID}" and return the .reference value for the selected result object.

Delphix engine use cases

Delphix user session timeout

Some activities can take longer than the default 30 minute session timeout value. Therefore, the following script allows you to change the timeout value using the RESTful API. As always, you can change it easily through the CLI.

 This code is the first example showing how object references are used for input (either JSON or URL) into API calls. The name will be the DE\_USER variable value delphix\_admin. The object reference that the code identifies is USER-2, which in this case is passed into the API URL to update the user parameters passed via the JSON string.

**Filename: user\_timeout.sh**

Edit the file to update the parameters as required for your environment.

```
#####
#   DELPHIX CORP   #
#####
#Parameter Initialization
DMIP=172.16.160.195
#DMPORT=8282
DMUSER=delphix_admin
DMPASS=delphix
COOKIE=~/.cookies.txt
COOKIE=`eval echo $COOKIE`
CONTENT_TYPE="Content-Type: application/json"
BaseURL="http://${DMIP}/resources/json/delphix"
```

```
#
Required for user timeout ...
#
DE_USER="delphix_admin" # Delphix Engine User
DE_TIMEOUT=120 # Timeout integer in minutes
#####
#   NO CHANGES REQUIRED BELOW THIS POINT   #
#####
```

### Sample Output

```
$ ./user_timeout.sh # or ./user_timeout_jq.sh
Authenticating on http://172.16.160.195/resources/json/delphix
Session and Login Successful ...
user reference: USER-2
Update delphix_admin session timeout value to 120 minutes ...
Returned JSON: {"type":"OKResult","status":"OK","result":"","job":null,"action":"ACTION-423"}
Results: OK
Done ...
$
```

### VDB Init (start | stop | enable | disable | status | delete)

This script is used to start, stop, enable, disable, and delete a Delphix platform source object. Typically, this is done on a virtual databases (VDBs), but you can use it for dSources as well.

 The `vdb_init.sh` and `vdb_operations.sh` require the "jq" command line json parser.

### Filename: `vdb_init.sh`

The `vdb_init.sh` supports the start, stop, enable, disable, status, and delete command line options.

```
$ ./vdb_init.sh something VBITT
. . .
Unknown option (start | stop | enable | disable | status | delete): something
Exiting ...
$ ./vdb_init.sh status VBITT
database container reference: ORACLE_DB_CONTAINER-121
source reference: ORACLE_VIRTUAL_SOURCE-25
Runtime Status: "INACTIVE"
Enabled: true
Done ...
```

```
$ ./vdb_init.sh start VBITT
database container reference: ORACLE_DB_CONTAINER-121
source reference: ORACLE_VIRTUAL_SOURCE-25
Job: JOB-894
Current status as of Wed Sep 7 16:04:04 EDT 2016 : RUNNING 0% Completed
```

```

Current status as of Wed Sep 7 16:04:14 EDT 2016 : RUNNING 25% Completed
Current status as of Wed Sep 7 16:04:24 EDT 2016 : RUNNING 45% Completed
Job: JOB-894 COMPLETED 100% Completed ...
Done ...

```

```

$ ./vdb_init.sh delete VBITT
database container reference: ORACLE_DB_CONTAINER-123
source reference: ORACLE_VIRTUAL_SOURCE-27
vendor source: OracleVirtualSource
delete parameters type: OracleDeleteParameters
Job: JOB-927
Current status as of Sat Sep 10 12:55:32 EDT 2016 : RUNNING 0% Completed
Current status as of Sat Sep 10 12:55:32 EDT 2016 : RUNNING 0% Completed
Job: JOB-927 COMPLETED 100% Completed ...
Done ...

```

### VDB operations (sync, refresh, rollback)

This script is used to perform a sync (snapshot), refresh, or rollback (reset) on the Delphix Engine source object. All these work on a virtual databases (VDBs), but only a sync operation can be used on dSources.

 The `vdb_init.sh` and `vdb_operations.sh` require the "jq" command line json parser.

### Filename: `vdb_operations.sh`

```

$ ./vdb_operations.sh sync VBITT
Session and Login Successful ...
database container reference: ORACLE_DB_CONTAINER-131
provision source container: ORACLE_DB_CONTAINER-129
json> {
  "type": "OracleSyncParameters"
}
Job: JOB-998
Current status as of Wed Sep 14 17:05:00 EDT 2016 : RUNNING 0% Completed

```

```

Current status as of Wed Sep 14 17:05:24 EDT 2016 : RUNNING 97% Completed
Job: JOB-998 COMPLETED 100% Completed ...
Done ...

```

Rollback rewinds the virtual database back to the last point in time within the source TimeFlow.

```

$ ./vdb_operations.sh rollback VBITT
Session and Login Successful ...
database container reference: ORACLE_DB_CONTAINER-131
provision source container: ORACLE_DB_CONTAINER-129
json> {
  "type": "OracleRollbackParameters",

```

```

    "timeflowPointParameters": {
      "type": "TimeflowPointSemantic",

## Masking use cases

### Masking API client

The Continuous Compliance Engine now features an interactive API client that can generate commands specific to your masking engine. With those commands, you can:

- make changes to your engine
- copy and paste the commands to write code that can automate your masking activities

The API client will make real changes to your virtual machine. Any operations you run using the API Client will persist on the machine!

To access the Masking API client, use the following URL: `http://myMaskingEngine.com/masking/api-client/`, replacing "myMaskingEngine.com" with the hostname or IP address of your virtual machine.

For detailed examples of using API calls to automate masking, see the [Masking APIs](#)

### Masking in Parallel

Continuous Compliance supports launching masking jobs in parallel. When jobs have no dependencies, you can initiate parallel masking API jobs (with wrapper code as required) to allow the jobs to be run as a pre and/or post hook.

Oracle use cases for APIs

Oracle link + snapshot (sync)

The following script ingests links an environment database dSource (Oracle SID / Instance) and then takes a snapshot. See parameters for required values that you must provide.

This script demonstrates how to use name values inputs and get the respective Delphix object and/or object reference for use in the json input in downstream API calls.

**Filename: link\_oracle.sh # or link\_oracle\_jq.sh**

Edit the file to update the parameters as required for your environment.

```

Oracle provision

**Filename: provision\_oracle.txt**

Shown below is how to use the CLI to provision an Oracle 11g database that is already ingested into the Delphix Engine.

The key is to get the object reference names first. For example, to get the source database container name:

```
ssh delphix_admin[delphix_engine_ip_address_or_hostname]> database> ls...> select
"[database_name]"> lsDelphix5002HWv7 database> select 'DPXDEV01'Delphix5002HWv7
database 'DPXDEV01'> lsProperties type: OracleDatabaseContainer name:
DPXDEV01 . . . reference: ORACLE_DB_CONTAINER-18 . . .
```

Minimum parameters required to provision:

```

Delphix5002HWv7 database provision > *commit=== POST /resources/json/delphix/
database/provision ==={   "type": "OracleProvisionParameters",   "container":
{       "type": "OracleDatabaseContainer",       "name": "VBITT" , # Delphix Object
Name, Typically matches VDB name       "group": "GROUP-36" # group ls select
"[group_name]" ls   },   "source": {       "type": "OracleVirtualSource",
"mountBase": "/mnt/provision" # Delphix Filesystem Mount path   },   "sour
ceConfig": {       "type": "OracleSIConfig",       "repository":
"ORACLE_INSTALL-3" , # repository, select "[repository_name]"       "databaseName":
"VBITT" , # New VDB Name       "uniqueName": "VBITT",       "instance":
{       "type": "OracleInstance",       "instanceName": "VBITT",
"instanceNumber": 1   }   },   "timeflowPointParameters": {       "type":
"timeflowPointSemantic",       "container": "ORACLE_DB_CONTAINER-18" # select
"[database_name]" ls   }}=== RESPONSE ===

```

### Sample CLI session

```

VBITT  Dispatched job JOB-348  DB_PROVISION job started for "Oracle Target
Virtual Databases/VBITT".  Starting provision of the virtual database "VBITT".  C
reating new TimeFlow.  Generating recovery scripts.  Exporting
storage.  Mounting filesystems for the virtual database instance "1".  Mounting
read-only archive log filesystem for the virtual database instance "1".  Recovering
Oracle database.  \|- Opening the virtual database "VBITT".  Opening Oracle
database.  Oracle recovery was successful.  Unmounting read-only archive log
filesystem for the virtual database instance "1".  The virtual database "VBITT" was
successfully provisioned.  DB_PROVISION job for "Oracle Target Virtual Databases/
VBITT" completed successfully.Delphix5002HWv7 database>

```

With the **setopt trace=true** option set, you can convert the JSON output from the above CLI provision command to the RESTful API cURL commands. If VBITT exists, be sure to delete it first.

Request:

```

curl X POST -k --data @http://172.16.160.177/resources/json/delphix/database/
provision \ -b cookies.txt -H "Content-Type: application/json" <<EOF{  "type":
"OracleProvisionParameters",  "container": {  "type":
"OracleDatabaseContainer",  "name": "VBITT",  "group": "GROUP-36"
},  "source": {  "type": "OracleVirtualSource",  "mountBase": "/
mnt/provision"  },  "sourceConfig": {  "type": "OracleSICongfig",
"repository": "ORACLE_INSTALL-3",  "databaseName": "VBITT",
"uniqueName": "VBITT",  "instance": {  "type":
"OracleInstance",  "instanceName": "VBITT",  "instanceNumber":
1  }  },  "timeflowPointParameters": {  "type":
"TimeflowPointSemantic",  "container": "ORACLE_DB_CONTAINER-18"  }}EOF

```

Response:

```
{"type":"OKResult","status":"OK","result":"ORACLE_DB_CONTAINER-22","job":"JOB-353",
"action":"ACTION-649"}
```

Put all the commands above within a shell script to automate the complete process of provisioning an Oracle 11.2.0.4 database.

Notice that the script below looks up 4 object references for use within the JSON input into the API.

**Filename: provision\_oracle.sh# or provision\_oracle\_jq.sh**

Edit the file to update the parameters as required for your environment.

```

## SQL server API use cases

## SQL server link/ingest environment dSource

For the **Window Target** environment, the dSource **delphixdb** in **MSSQLSERVER** instance will be linked/ingested into the Delphix Engine. It will appear in the **Windows\_Source** group below.

Filename: *link\_sqlserver.ps1*

```
PS> . .\link_sqlserver.ps1Authenticating on http://172.16.160.195/resources/json/
delphixLogin Successful ...group reference: GROUP-34 sourceconfig reference:
MSSQL_SINGLE_CONFIG-26 env reference: WINDOWS_HOST_ENVIRONMENT-7 repository
reference: MSSQL_INSTANCE-4 database link API Results:
{"type":"OKResult","status":"OK","result":"MSSQL_DB_CONTAINER-114","job":"JOB-819","a
ction":"ACTION-1659"}DB Container: MSSQL_DB_CONTAINER-114
```

```
Job # JOB-819***** waiting for status *****Current status as of 09/05/2016 11:4
1:13 : COMPLETED : 100.0% CompletedJob COMPLETED Successfully.
```

```
JOB JOB-820waiting for status *****Current status as of 09/05/2016 11:41:23 :
RUNNING : 5.0% CompletedCurrent status as of 09/05/2016 11:41:44 : RUNNING : 9.0%
Completed
```

```
Current status as of 09/05/2016 11:41:54 : RUNNING : 56.0% CompletedJob COMPLETED
Successfully. Done ...
```

Successful dSource linked/ingested into the Delphix Engine.

## SQL server provision

The example below is done from the command line once you know the parameters and reference object names.

Filename: *windows\_sqlserver\_provision.txt*

Create these 3 JSON text files:

```
session.json{  "type": "APISession",  "version": {      "type": "APIVersion",
    "major": 1,      "minor": 5,      "micro": 3  }} login.json{  "type":
"LoginRequest",  "username": "delphix_admin",  "password": "delphix"}
provision.json{  "type": "MSSqlProvisionParameters",  "container": {      "type
": "MSSqlDatabaseContainer",      "name": "Vbitt00",      "group": "GROUP-36",
    "sourcingPolicy": {          "type": "SourcingPolicy",          "loadFromBac
kup": false,          "logsyncEnabled": false      },          "validatedSyncMode":
"TRANSACTION_LOG"      },      "source": {          "type": "MSSqlVirtualSource",          "o
perations": {              "type": "VirtualSourceOperations",              "configureClon
e": [],              "postRefresh": [],              "postRollback": [],              "post
Snapshot": [],              "preRefresh": [],              "preSnapshot":
[]          }      },      "sourceConfig": {          "type": "MSSqlSIConfig",          "linkin
```

```
gEnabled": false,      "repository": "MSSQL_INSTANCE-1",      "databaseName":
"Vbitt00",      "recoveryModel": "SIMPLE",      "instance": {      "type":
"MSSqlInstanceConfig",      "host": "WINDOWS_HOST-1"      }      },      "timeflo
wPointParameters": {      "type": "TimeflowPointSemantic",      "container":
"MSSQL_DB_CONTAINER-23",      "location": "LATEST_SNAPSHOT"      }}
```

This works on Windows Powershell Command Prompt

 Use curl, curl.exe or modify the default alias.

```
curl --insecure -c cookies.txt -i -X POST -H "Content-Type: application/json" -d
"@session.json" http://172.16.160.153/resources/json/delphix/sessioncurl --insecure
-b cookies.txt -i -X POST -H "Content-Type: application/json" -d "@login.json"
http://172.16.160.153/resources/json/delphix/logincurl --insecure -b cookies.txt -i
-X POST -H "Content-Type: application/json" -d "@provision.json" http://
172.16.160.153/resources/json/delphix/database/provision
```

Plug in the returned JOB #

```
curl --insecure -b cookies.txt -i -X GET -H "Content-Type: application/json" -k http:/
/172.16.160.153/resources/json/delphix/notification?channel=JOB-428
```

Get Example

```
curl --insecure -b cookies.txt -i -X GET -H "Content-Type: application/json" -k http:/
/172.16.160.153/resources/json/delphix/system
```

Complete example.

Provision the newly created **delphixdb** dSource in the **Windows\_Source** group to a virtual database VBITT in the **Windows\_Target** group.

Filename: *provision\_sqlserver.ps1*

Variables ...

```

[ Observer Delphix GUI Action ]

Done with SQL Server VDB Refresh ...

## API programming language examples

The following programming language examples are just to show the bare minimum authentication and a sample functional API call. There are numerous modules, libraries, methods, functions, and code examples to further demonstrate how the languages work with the Delphix APIs and JSON data strings/objects.

You can execute PHP, Perl, and Python languages from the command line and/or from within a Web Server such as Apache or IIS. The following examples are formatted for command line / terminal output.

### PHP

PHP provides cURL and JSON modules.

```
$ php -i | grep -iE "cURL|json"curlcURL support => enabledcURL Information => 7.43.0j
sonjson support => enabledjson version => 1.2.1
```

Filename: *delphix\_curl.php*

Sample Output:

```
$ php -f delphix_curl.phpSession json> {"type":"APISession","version":{"type":"APIVer
sion","major":1,"minor":7,"micro":0}} Session Results> {"type":"OKResult","status":"O
K","result":{"type":"APISession","version":{"type":"APIVersion","major":1,"minor":7,"
micro":0},"locale":null,"client":null},"job":null,"action":null} Login json> {"type":"
LoginRequest","username":"delphix_admin","password":"delphix"} Login Results> {"type":"
OKResult","status":"OK","result":"USER-2","job":null,"action":null} Calling About
API ...About Results> {"type":"OKResult","status":"OK","result":{"type":"PublicSystem
Info","productType":"standard","productName":"Delphix Engine","buildTitle":"Delphix
Engine 5.1.1.0","buildTimestamp":"2016-07-21T07:23:41.000Z","buildVersion":{"type":"V
ersionInfo","major":5,"minor":1,"micro":1,"patch":0},"configured":true,
"enabledFeatures":["XPP","MSSQLHOOKS"],"apiVersion":{"type":"APIVersion","major":1,"m
inor":8,"micro":0},"banner":null,"locales":["en-US"],"currentLocale":"en-US"},"job":n
ull,"action":null} Converting json string to a PHP Array stdClass Object( [type]
=> OKResult [status] => OK [result] => stdClass
Object ( [type] => PublicSystemInfo [productType] =>
standard [productName] => Delphix Engine [buildTitle] =>
Delphix Engine 5.1.1.0 [buildTimestamp] => 2016-07-21T07:23:41.000Z
[buildVersion] => stdClass Object ( [type] =>
VersionInfo [major] => 5 [minor] => 1
[micro] => 1 [patch] => 0 ) [c
onfigured] => 1 [enabledFeatures] =>
Array ( [0] => XPP [1] =>

APIVersion [major] => 1 [minor] => 8
[micro] => 0 ) [banner] =>
=> Array ( [0] => en-US )
[currentLocale] => en-US ) [job] => [action] => )
```

## Perl

Perl provides a couple of methods for working with cURL: operating system calls, WWW::Curl (libcurl) module, or LWP::Curl module. The sample below simply logs into the Delphix Engine and lists the current Delphix Environments.

Filename: [perl\\_curl.pl](#)

Sample Output:

```
$ perl perl_curl.plTesting cURL on Perl ...Session Results: {"type":"OKResult","status":"OK","result":{"type":"APISession","version":{"type":"APIVersion","major":1,"minor":7,"micro":0},"locale":null,"client":null},"job":null,"action":null} Login Results: {"type":"OKResult","status":"OK","result":"USER-2","job":null,"action":null} Environment Results: {"type":"ListResult","status":"OK","result":[{"type":"WindowsHostEnvironment","reference":"WINDOWS_HOST_ENVIRONMENT-7","namespace":null,"name":"Window Target","description":null,"primaryUser":"HOST_USER-7","enabled":false,"host":"WINDOWS_HOST-6","proxy":null},{"type":"UnixHostEnvironment","reference":"UNIX_HOST_ENVIRONMENT-9","namespace":null,"name":"Oracle Target","description":"","primaryUser":"HOST_USER-9","enabled":true,"host":"UNIX_HOST-8","aseHostEnvironmentParameters":null}],"job":null,"action":null,"total":2,"overflow":false} Done
```

## Python

Delphix has an extensive resource library for using Python with the Delphix Engine.

[CLI to Python transition](#)

```

## JSP (Java server pages)

Java Server Pages are typically used for the web formatting and output, but you can also use JSP for application logic processing and native Java code integration, although this is scorned by the purest and most logical thinking programmers.

Filename: *delphix\_http.jsp*

Sample Output:

Browser URL: [http://localhost:8080/delphix\\_http.jsp](http://localhost:8080/delphix_http.jsp)

```
← → ↻ 🏠 localhost:8080/delphix_http.jsp

## Java

Java methods and classes allow coding logic to be effectively re-used, extended and modularized for flexible applications. Using the Java code embedded within the JSP file, code is logically placed into respective classes and methods.

## API timeflows

From earlier, the RESTful URL for a virtual database refresh will look like:

**http://<delphix\_engine>/resources/json/delphix/database/MSSQL\_DB\_CONTAINER-39/refresh**

where the **MSSQL\_DB\_CONTAINER-39** represents the target virtualized database to refresh and we need to POST the JSON data to the URL for processing.

```
{  "type": "RefreshParameters",  "timeflowPointParameters": {  "type": "TimeflowPointSemantic",  "container": "MSSQL_DB_CONTAINER-38"  }}
```

### Timeflow parameters

The **"timeflowPointParameters"** key has 6 **"type": "..."** options which each have their own set of parameters. The type **"TimeflowPointSemantic"** uses the default LATEST\_POINT within the source container. Now, for more on timeflowPointParameters.

*http://<delphix\_engine>/api/#TimeflowPointParameters*

#### TimeflowPointParameters

Parameters indicating a TimeFlow point to use as input to database operations.

TypedObject

TimeflowPointParameters

Direct Known Subclasses:

TimeflowPointTimestamp, TimeflowPointSnapshot, TimeflowPointSemantic, TimeflowPointLocation, TimeflowPointBookmark, TimeflowPointBookmarkTag

#### TimeflowPointTimestamp

timeflow	Reference to TimeFlow containing this point. Type: Reference to Timeflow Constraints: Required: true
timestamp	The logical time corresponding to the TimeFlow location. Type: date Constraints: Required: true

#### TimeflowPointSnapshot

snapshot	Reference to the snapshot. Type: Reference to TimeflowSnapshot
----------	-------------------------------------------------------------------

#### TimeflowPointSemantic

Semantic reference to a Timeflow point.

**⚠** The reference is relative to a container and not a TimeFlow. If the container contains multiple TimeFlows, the Delphix Engine will evaluate the semantic reference with regards to all TimeFlows in that container.

container	Reference to the container. Type: Reference to Container Constraints: Required: true
location	A semantic description of a TimeFlow location. Type: string Constraints: Default: LATEST_POINT Acceptable values: LATEST_POINT, LATEST_SNAPSHOT Create: optional Update: optional

#### TimeflowPointLocation

TimeFlow point based on a database-specific identifier (SCN, LSN, etc).

location	The TimeFlow location. Type: string Constraints: Required: true
timeflow	Reference to TimeFlow containing this location. Type: Reference to Timeflow Constraints: Required: true

#### TimeflowPointBookmark

bookmark	Reference to the bookmark. Type: Reference to TimeflowBookmark Constraints: Required: true
----------	--------------------------------------------------------------------------------------------------

#### TimeflowPointBookmarkTag

container	Reference to the container. Type: Reference to Container Constraints: Required: true
tag	The name of the tag. Type: string Constraints: Required: true

Timeflow API objects: timeflow, snapshot, timeflowRanges

The sample code provides information on the Timeflow, timeflowRanges and snapshot objects for the respective VDB.

Filename: flows.sh

```
$ ./flows.sh VBITT10Session API Login API Login {"type":"OKResult","status":"OK","result":"USER-2","job":null,"action":null}Source: VBITT10container reference:

- [API Cookbook: delete Delphix self-service template](#)
- [API Cookbook: uploadUpgrade](#)

## API cookbook: authentication

This API cookbook recipe describes how to create an authenticated session for using the Delphix Sever web services.

Before you can use any Delphix Web Service API's you need to create a session, and then authenticate the session by providing valid Delphix account credentials.

## Create Delphix API Session

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/session \
-c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "APISession",
  "version": {
    "type": "APIVersion",
    "major": 1,
    "minor": 4,
    "micro": 3
  }
}
EOF

Response
{
  "status": "OK",
  "result": {
    "type": "APISession",
    "version": {
      "type": "APIVersion",
      "major": 1,
      "minor": 4,
      "micro": 3
    },
    "locale": "en_US",
    "client": null
  },
  "job": null
}
EOF
```

Once the session has been established, the next step is to authenticate to the server by executing the `LoginRequest` API. Unauthenticated sessions are prohibited from making any API calls other than this login request. The username can be either a system user or domain user, and the backend will authenticate using the appropriate method. This example illustrates logging in via curl using cookies created when the session was established:

```
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/login \
-b cookies.txt -c cookies2.txt -H "Content-Type: application/json" <<EOF
{
  "type": "LoginRequest",
  "username": "delphix_user",
```

```
"password": "delphix_pass",  
"target": "DOMAIN"  
}  
EOF
```

The new cookie (cookie2.txt) will need to be used in subsequent API requests. The login API currently only supports authentication by a password. There is no way to authenticate using any shared key or alternate authentication strategy.

It is generally recommended to set the API session version to the [highest level supported](#) by your Delphix Engine.

## API cookbook: host environment details

This API cookbook recipe describes how to obtain host environment details using the Delphix Engine API.

To obtain details about target host environments, list available `Environment` objects on the system. These environments can represent either a single host, or an Oracle cluster.

### List Environment

```
curl -X GET -k http://delphix-server/resources/json/delphix/environment \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For single-host environments, the reference can be used to get information about the associated host. It is also possible to get information about all hosts (regardless of whether they are in a single-host environment or cluster) by omitting the `environment` query parameter.

### List UNIX Environment

```
curl -X GET -k http://services.cloud.skytap.com:23173/resources/json/delphix/host?
environment=UNIX_HOST_ENVIRONMENT-1 \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For more information about the content of host objects, see the `/api/#Host` reference on your local Delphix Engine. Depending on the type of the host, additional information may be available through the following types:

- `UnixHost`
- `WindowsHost`

## API cookbook: list alerts and list jobs

This API cookbook recipe describes how to obtain lists of jobs and alerts using the Delphix Engine API.

The `List Alerts` and `List Jobs` API calls can both accept the `toDate` and `fromDate` query parameters to limit rows returned. These parameters require the date to be expressed in [ISO 8601](#) format.

### List Alerts

```
$ curl -X GET -k http://delphix-server/resources/json/delphix/alert \  
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For more information about the structure of an alert object, see the `/api/#Alert` link on your local Delphix Engine.

### List Jobs (using fromDate)

```
$ curl -X GET -k http://delphix-server/resources/json/delphix/job? \  
  addEvents=true&fromDate=2012-11-08T00:00:00.0000Z \  
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For more information about the structure of a job object, see the `/api/#Job` link on your local Delphix Engine.

## API cookbook: list dSources and VDBs

This API cookbook recipe describes how to obtain a list of dSources and VDBs using the Delphix Engine API.

To obtain a list of dSources and VDBs, list available `Container` (also known as `database`) objects on the system:

### List Databases

```
$ curl -X GET -k http://delphix-server/resources/json/delphix/database \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For more information on the structure of a database object, see the `/api/#Container` reference on your local Delphix Engine. The following sub-types are available depending on the type of database:

- `OracleDatabaseContainer`
- `MSSqlDatabaseContainer`

Each database has zero or one source associated with it. This source could be a linked source, indicating that the database is a dSource, or it could be a virtual source, indicating that it is a VDB. If there are no sources, it is a detached dSource. The `parentContainer` property indicates the reference to the parent container, also indicating that the database is a VDB. To get runtime information about the source associated with the dSource or VDB, use the `Source` API with a `database` parameter set to the reference of the database in question.

### List Sources

```
$ curl -X GET -k http://delphix-server/resources/json/delphix/source?
  database=DB_CONTAINER-13 \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

If the `virtual` flag is true, the source is a VDB, otherwise it is a dSource. For more information about the contents of a source object, see the `/api/#Source` reference on your local Delphix Engine. The following sub-types are available depending on the type of source:

- `OracleSource`
  - `OracleLinkedSource`
  - `OracleVirtualSource`
- `MSSqlSource`
  - `MSSqlLinkedSource`
  - `MSSqlVirtualSource`

## API cookbook: list snapshots

This API cookbook recipe describes how to obtain a list of available snapshots for a VDB or dSource.

Snapshots represent points in time where a `sync` operation has occurred on either a dSource or VDB.

Provisioning from snapshots is much faster than provisioning between snapshots, as the latter requires replaying LogSync records to arrive at the requested point. Given a reference to a database, the `snapshot` API can be used to retrieve the set of snapshots within the database. See the topic [API Cookbook: List dSources and VDBs](#) for information on how to obtain the database reference.

### List Snapshots

```
curl -X GET -k http://services.cloud.skytap.com:23173/resources/json/delphix/
snapshot?database=ORACLE_DB_CONTAINER-15 \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

For more information about the structure of a snapshot object, see the `/api/#TimeflowSnapshot` reference on your local Delphix Engine. Snapshots, while representing the point where provisioning will be most efficient, are not the only provisionable points within a database. To get a list of all provisioning points, use the `timeflowRange` API. This API is based on a Timeflow, which is the representation of one timeline within a database. Currently, all databases have a single Timeflow, though this may change in the future. To query for the ranges for a particular database, you will need to use the `currentTimeflow` member of the target database.

### List Timeflow Ranges

```
curl -X POST -k --data @- http://services.cloud.skytap.com:23173/resources/json/
delphix/timeflow/ORACLE_TIMEFLOW-11/timeflowRanges \
  -b ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "TimeflowRangeParameters"
}
EOF
```

API cookbook: example provision of an Oracle VDB

This API cookbook recipe demonstrates how to provision an Oracle VDB using the Delphix Engine API.

In order to provision an Oracle VDB using the API, you need to provide a set of parameters of type **OracleProvisionParameters** (having already authenticated as per [API Cookbook: Authentication](#)).

There are a number of parameters you will need to know:

- **Group reference** - See the list operation in `"/api#group"` on your Delphix Engine
- **VDB name** - The name you want the new VDB to be called
- **Mount path** - Where to mount datasets on the target host.
- **DB/unique names** - The Oracle DB and unique names, often the same as the VDB name
- **Instance name/number** - The Oracle instance name and number to use (dictated by your environment, but often VDB name and 1)
- **Repository reference** - See the list operation on `"/api#repository"` on your Delphix Engine
- **TimeFlow point** - See [API Cookbook: List Snapshots](#) for more information on finding a TimeFlow point, as well as the reference at `"/api#TimeflowPoint Parameters`

You will need to use the structure of the OracleProvisionParameters object to fill it out, see `"/api/#OracleProvisionParameters"` for details on which fields are mandatory/optional.

Here is a minimal example using curl to communicate with the API, provisioning a VDB called "EGVDB" (authentication omitted)

```
curl -X POST -k --data @- http://delphix1.company.com/resources/json/delphix/
database/provision \
-b cookies.txt -H "Content-Type: application/json" <<EOF
{
  "container": {
    "group": "GROUP-2",
    "name": "EGVDB",
    "type": "OracleDatabaseContainer"
  },
  "source": {
    "type": "OracleVirtualSource",
    "mountBase": "/mnt/provision",
    "allowAutoVDBRestartOnHostReboot": true
  },
  "sourceConfig": {
    "type": "OracleSIConfig",
    "databaseName": "EGVDB",
    "uniqueName": "EGVDB",
    "repository": "ORACLE_INSTALL-3",
    "instance": {
      "type": "OracleInstance",
      "instanceName": "EGVDB",
      "instanceNumber": 1
    }
  },
  "timeflowPointParameters": {
    "type": "TimeflowPointLocation",
    "timeflow": "ORACLE_TIMEFLOW-123",
    "location": "3043123"
  }
}
```

```
    },  
    "type": "OracleProvisionParameters"  
  }  
EOF
```

## API cookbook: refresh VDB

This API cookbook recipe describes how to refresh a VDB using the Delphix Engine API.

To refresh a VDB you need a reference to the `Database` object, the location of the point to which you wish to refresh and the reference container associated with the object. See the topic [API Cookbook: List dSources and VDBs](#) for information on how to obtain the database reference and current Timeflow. The Timeflow point can be specified either by timestamp, by location (SCN), semantic location or Timeflow bookmark. The `TimeflowPointSemantic` type allows you to specify a semantically meaningful Timeflow location (i.e. the latest snapshot or the latest Timeflow point). The `TimeflowPointBookmark` type allows you to reference a previously created Timeflow bookmark. See [API Cookbook: List Snapshots](#) topic for information on how to determine provisionable points in the parent database.

### Refresh VDB

```
curl -v -X POST -k --data @- http://delphix-server/resources/json/delphix/database/  
ORACLE_DB_CONTAINER-13/refresh \  
-b ~/cookies.txt -H "Content-Type: application/json" <<EOF  
{  
  "type": "OracleRefreshParameters",  
  "timeflowPointParameters": {  
    "type": "TimeflowPointSemantic",  
    "container": "ORACLE_DB_CONTAINER-1",  
    "timeflow": "ORACLE_TIMEFLOW-13",  
    "location": "LATEST_SNAPSHOT"  
  }  
}  
EOF
```

For more information about the content of refresh parameters, see the `/api/#RefreshParameters` reference on your local Delphix Engine. Depending on the type of the database, the following parameter types are available:

- `OracleRefreshParameters`
- `MSSqlRefreshParameters`

## API cookbook: rewind a VDB

This API cookbook recipe describes how to rewind a VDB using the Delphix Engine API.

To rewind a VDB, you need a reference to the `Database` object. See the topic, [API Cookbook: List dSources and VDBs](#), for information on how to obtain the database reference. The following sample script includes a working example for creating a session, authenticating to the Delphix Engine, and rewinding the VDB. Please update the script variables to match your environment before using it.

```
#!/bin/bash
#
# sample script to start or stop a VDB.
#
# set this to the FQDN or IP address of the Delphix Engine
DE="192.168.2.131"
# set this to the Delphix admin user name
DELPHIX_ADMIN="delphix_admin"
# set this to the password for the Delphix admin user
DELPHIX_PASS="delphix"
# set this to the object reference for the VDB
VDB="ORACLE_DB_CONTAINER-57"
#
# create our session
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/session \

    -c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "APISession",
  "version": {
    "type": "APIVersion",
    "major": 1,
    "minor": 4,
    "micro": 3
  }
}
EOF
{
  "status":"OK",
  "result": {
    "type":"APISession",
    "version": {
      "type": "APIVersion",
      "major": 1,
      "minor": 4,
      "micro": 3
    },
    "locale": "en_US",
    "client": null
  },
  "job": null
}
EOF
```

```

echo
#
# authenticate to the DE
$ curl -s -X POST -k --data @- http://delphix-server/resources/json/delphix/login \
  -b ~/cookies.txt -c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "LoginRequest",
  "username": "delphix_username",
  "password": "delphix_password"
}

EOF
echo
#
# rewind VDB
curl -s -X POST -k --data @- http://${DE}/resources/json/delphix/database/${VDB}/
rollback \
  -b ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "OracleRollbackParameters",
  "timeflowPointParameters": {
    "type" : "TimeflowPointSnapshot",
    "snapshot" : "ORACLE_SNAPSHOT-172"
  }
}
EOF
echo

```

**⚠** While rewinding a VDB, you can use different parameter types. In the above example, "timeflowPointParameters" type is used as "TimeflowPointSnapshot" and an appropriate snapshot name is provided. Instead of "TimeflowPointSnapshot", you can also choose from "TimeflowPointLocation" or "TimeflowPointTimestamp" or "TimeflowPointBookmark" etc. and pass the relevant parameters.

You can list your Snapshots by following the instructions on [API Cookbook: List Snapshots](#)

## API cookbook: stop/start a VDB

This API cookbook recipe describes how to stop and start a VDB using the Delphix Engine API.

To stop or start a VDB, you need a reference to the `Database` object. See the topic, [API Cookbook: List dSources and VDBs](#), for information on how to obtain the database reference. The following script example includes working examples for creating a session, authenticating to the Delphix Engine, and stopping or starting a VDB. Please update the script variables to match your environment before using it. This script requires a single argument which is 'start' or 'stop'.

```
#!/bin/bash
#
# sample script to start or stop a VDB.
#
# set this to the FQDN or IP address of the Delphix Engine
DE="192.168.2.131"
# set this to the Delphix admin user name
DELPHIX_ADMIN="delphix_admin"
# set this to the password for the Delphix admin user
DELPHIX_PASS="delphix"
# set this to the object reference for the VDB
VDB="ORACLE_VIRTUAL_SOURCE-5"
#
# create our session
curl -s -X POST -k --data @- http://${DE}/resources/json/delphix/session \
  -c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "APISession",
  "version": {
    "type": "APIVersion",
    "major": 1,
    "minor": 11,
    "micro": 8
  }
}
EOF
echo
#
# authenticate to the DE
curl -s -X POST -k --data @- http://${DE}/resources/json/delphix/login \
  -c ~/cookies.txt -b ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "LoginRequest",
  "username": "${DELPHIX_ADMIN}",
  "password": "${DELPHIX_PASS}"
}
EOF
echo
#
# start or stop the vdb based on the argument passed to the script
case $1 in
start)
```

```
curl -s -X POST -k http://${DE}/resources/json/delphix/source/${VDB}/start \  
  -c ~/cookies.txt -b ~/cookies.txt -H "Content-Type: application/json" \  
;; \  
stop) \  
  curl -s -X POST -k http://${DE}/resources/json/delphix/source/${VDB}/stop \  
  -c ~/cookies.txt -b ~/cookies.txt -H "Content-Type: application/json" \  
;; \  
*) \  
  echo "Unknown option: $1" \  
;; \  
esac \  
echo
```

API cookbook: creating a database template in Delphix self-service

 **Jet Stream is now known as Delphix Self-Service.**

Delphix Self-Service administrators can use this API cookbook recipe to create a database template on Delphix Self-Service using the Delphix Engine API.

 **The following script is for educational and demonstration purposes only and is not supported by Delphix.**

The following script can be downloaded by selecting [createDBTemplate.sh](#)

Create Self-Service Database Template

```
#!/bin/bash

# A sample script for calls to the API. This one creates a Jet Stream Template.

##### Constants

# Describes a Delphix software revision.
# Please change version are per your Delphix Engine CLI, if different
VERSION="1.8.0"

##### Default Values. These can be overwritten with optional arguments.
engine="172.16.151.154"
username="delphix_admin"
password="landshark"

##examples##
# Create template with mandatory params
#./createBranch.sh -d 172.16.151.154 -u delphix_admin:landshark -n <sourceName>
<templateName> <containerName>
#Ex ./createBranch.sh -d 172.16.151.154 -u delphix_admin:landshark -n oraclesrc
template1 ORACLE_DB_CONTAINER-191
# Create template with adding optional params, Notes and Description
#./createDBTemplate.sh -n <sourceName> -N "<templateNotes>" -D "<AnyDescription>"
<templateName> <containerName>

## NOTE: This script is to add one source per template and it will not add any
properties for template, container or source.

##### Functions

# Help Menu
function usage {
    echo "Usage: createDBTemplate.sh [[-h] | options...] <template_name>

API cookbook: creating a container in Delphix self-service

Delphix Self-Service administrators can use this API cookbook recipe to create a container on Delphix Self-Service (Jet Stream) using the Delphix Engine API.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [createContainer.sh](#)

Create Self-Service Container

```
#!/bin/bash

# A sample script for calls to the API. This one creates a Jet Stream container.

##### Constants

# Describes a Delphix software revision.
# Please change version are per your Delphix Engine CLI, if different
VERSION="1.11.10"

##### Default Values. These can be overwritten with optional arguments.
engine="10.110.248.170"
username="admin"
password="delphix"

##examples##
# Create container from latest point in time
#./createContainer.sh -n "testsource" testcont ORACLE_DB_CONTAINER-269
JS_DATA_TEMPLATE-13
# Create container from specific bookmark
#./createContainer.sh -n "testsource" -b JS_BOOKMARK-77 testcont ORACLE_DB_CONTAINER-2
69 JS_DATA_TEMPLATE-13
# Create container from specific point in time
#./createContainer.sh -n "testsource" -t "2016-08-08T10:00:00.000Z" -B JS_BRANCH-50
testcont ORACLE_DB_CONTAINER-269 JS_DATA_TEMPLATE-13

#NOTE: this script will add one container and assign one owner for the container.

##### Functions

# Help Menu
function usage {
    echo "Usage: createContainer.sh [[-h] | options...] <containername> <vdb>
<template>"
    echo "Create a Jet Stream Bookmark on the given branch."
    echo ""

API cookbook: refreshing a container in Delphix self-service

Delphix Self-Service administrators can use this API cookbook recipe to refresh a container in Delphix Self-Service (Jet Stream) using the Delphix Engine API.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [refreshContainer.sh](#)

Refreshing a Self-Service container

```
#!/bin/bash

# A sample script for calls to the API. This one refresh Jet Stream container.

##### Constants

# Describes a Delphix software revision.
# Please change version are per your Delphix Engine CLI, if different
VERSION="1.8.0"

##### Default Values. These can be overwritten with optional arguments.
engine="172.16.151.154"
username="delphix_admin"
password="landshark"

##examples##
# Refresh container from latest point in time of Template
#./refreshContainer.sh -T JS_DATA_TEMPLATE-13 JS_DATA_CONTAINER-20
# Refresh container from specific bookmark
#./refreshContainer.sh -b JS_BOOKMARK-76 JS_DATA_CONTAINER-20
# Refresh container from specific point in time of branch
#./refreshContainer.sh -t "2016-08-08T10:00:00.000Z" -B JS_BRANCH-50
JS_DATA_CONTAINER-20

API cookbook: delete a bookmark in Delphix self-service

This API cookbook recipe describes how to delete a bookmark in Delphix Self-Service (Jet Stream).

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

Deleting a bookmark in Self-Service

```
#!/bin/bash
#
# sample script to delete a bookmark on a Jet Stream container.
#
# Please set the following variables to suit your purposes.
# set this to the FQDN or IP address of the Delphix Engine
DE="ars-dlpx-6010-3.dlpxdc.co"
# set this to the Delphix admin user name
DELPHIX_ADMIN="admin"
# set this to the password for the Delphix admin user
DELPHIX_PASS="delphix"
# reference of bookmark you want to delete
BOOKMARK_REF="JS_BOOKMARK-2"
#
# create our session
curl -s -X POST -k --data @- http://${DE}/resources/json/delphix/session \
  -c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "APISession",
  "version": {
    "type": "APIVersion",
    "major": 1,
    "minor": 6,
    "micro": 2
  }
}
EOF
echo
#
# authenticate to the DE
curl -s -X POST -k --data @- http://${DE}/resources/json/delphix/login \
  -b ~/cookies.txt -c ~/cookies.txt -H "Content-Type: application/json" <<EOF
{
  "type": "LoginRequest",
  "username": "${DELPHIX_ADMIN}",
  "password": "${DELPHIX_PASS}"
}
EOF
echo
#
# delete the bookmark
curl -s -X DELETE -k http://${DE}/resources/json/delphix/jetstream/bookmark/${
BOOKMARK_REF} \
  -b ~/cookies.txt -H "Content-Type: application/json"
```

echo

API cookbook: share a bookmark in Delphix self-service

Delphix Self-Service administrators can use this API cookbook recipe to share a bookmark in Delphix Self-Service (Jet Stream) using the Delphix Engine API.

 The following script is for educational and demonstration purposes only and is not supported by Delphix.

This script can be downloaded by selecting [shareBookmark.sh](#)

```
#!/bin/bash

# A sample script for calls to the API. This one shares Bookmark across containers in
# same template.

##### Constants

# Describes a Delphix software revision.
# Please change version are per your Delphix Engine CLI, if different.
VERSION="1.11.10"

##### Default Values. These can be overwritten with optional arguments.
engine="ars-dlpx-6010-3.dlpxdc.co"
username="admin"
password="delphix"

##examples##
# Share Bookmark
#./shareBookmark.sh -a share JS_BOOKMARK-75
# Unshare Bookmark
#./shareBookmark.sh -a unshare JS_BOOKMARK-75

Kerberos APIs

## API cookbook: ASEDBConfig

This API cookbook recipe describes how to configure your SAP ASE database using the Delphix Engine API.

```
{
  "name": "ASEDBConfig",
  "description": "A SAP ASE Database Config.",
  "abstract": true,
  "extends": {
    "$ref": "/delphix-source-config.json"
  },
  "properties": {
    "databaseName": {
      "type": "string",
      "description": "The name of the database.",
      "create": "required",
      "update": "optional",
      "pattern": "^[a-zA-Z0-9_]+$",
      "maxLength": 30
    },
    "user": {
      "type": "string",
      "description": "The username of the database user.",
      "update": "optional",
      "maxLength": 256
    },
    "credentials": {
      "type": "object",
      "description": "The password of the database user.",
      "$ref": "/delphix-credential.json",
      "update": "optional"
    },
    "repository": {
      "type": "string",
      "description": "The object reference of the source repository.",
      "format": "objectReference",
      "referenceTo": "/delphix-ase-instance.json",
      "create": "required",
      "update": "optional"
    }
  }
}
```

## API cookbook: ASEHostEnvironmentParameters

This API cookbook recipe describes how to configure your SAP ASE host environment parameters using the Delphix Engine API.

```
{
  "name": "ASEHostEnvironmentParameters",
  "description": "SAP ASE host environment parameters.",
  "extends": {
    "$ref": "/delphix-typed-object.json"
  },
  "properties": {
    "dbUser": {
      "type": "string",
      "description": "The username of the database user.",
      "create": "optional",
      "update": "optional",
      "maxLength": 256
    },
    "credentials": {
      "type": "object",
      "description": "The credentials of the database user.",
      "$ref": "/delphix-credential.json",
      "create": "required",
      "update": "optional",
      "properties": {
        "type": {
          "type": "string",
          "description": "Object type.",
          "required": true,
          "format": "type",
          "default": "PasswordCredential"
        }
      }
    }
  }
}
```

## API cookbook: SAP ASE instance

This API cookbook recipe describes how to configure your SAP ASE instance using the Delphix Engine API.

```
{
  "name": "ASEInstance",
  "description": "The SAP ASE source repository.",
  "extends": {
    "$ref": "/delphix-source-repository.json"
  },
  "properties": {
    "instanceName": {
      "type": "string",
      "description": "The name of the SAP ASE instance.",
      "create": "required"
    },
    "installationPath": {
      "type": "string",
      "description": "The SAP ASE instance home.",
      "create": "required",
      "update": "optional"
    },
    "ports": {
      "type": "array",
      "description": "The network ports for connecting to the SAP ASE
instance.",
      "items": {
        type: "integer"
      },
      "create": "required",
      "update": "optional"
    },
    "instanceOwner": {
      "type": "string",
      "description": "The username of the account the SAP ASE instance is
running as.",
      "create": "required",
      "update": "optional"
    },
    "instanceOwnerUid": {
      "type": "integer",
      "description": "The uid of the account the SAP ASE instance is running
as.",
      "create": "readonly",
      "update": "readonly"
    },
    "instanceOwnerGid": {
      "type": "integer",
      "description": "The gid of the account the SAP ASE instance is running
as.",
      "create": "readonly",
      "update": "readonly"
    }
  }
}
```

```

    },
    "pageSize": {
      "type": "integer",
      "description": "Database page size for the SAP ASE instance."
    },
    },
    "servicePrincipalName": {
      "type": "string",
      "description": "The Kerberos SPN of the database.",
      "create": "optional",
      "update": "optional"
    },
    },
    "dbUser": {
      "type": "string",
      "description": "The username of the database user.",
      "create": "optional",
      "update": "optional",
      "maxLength": 256
    },
    },
    "isqlPath" : {
      "type" : "string",
      "description" : "The path to the isql binary to use for this SAP ASE
instance.",
      "create" : "optional",
      "update" : "optional"
    },
    },
    "credentials": {
      "type": "object",
      "description": "The credentials of the database user.",
      "$ref": "/delphix-credential.json",
      "create": "optional",
      "update": "optional",
      "properties": {
        "type": {
          "type": "string",
          "description": "Object type.",
          "required": true,
          "format": "type",
          "default": "PasswordCredential"
        }
      }
    },
    },
    "discovered": {
      "type": "boolean",
      "description": "True if the SAP ASE instance was automatically
discovered."
    }
  }
}

```

## API cookbook: ASELinkData

This API cookbook recipe describes how to configure your SAP ASE link data using the Delphix Engine API.

```
{
  "name": "ASELinkData",
  "description": "SAP ASE specific parameters for a link request.",
  "extends": {
    "$ref": "/delphix-link-data.json"
  },
  "properties": {
    "config": {
      "type": "string",
      "description": "Reference to the configuration for the source.",
      "format": "objectReference",
      "referenceTo": "/delphix-ase-db-config.json",
      "required": true
    },
    "externalFilePath": {
      "type": "string",
      "description": "External file path.",
      "maxLength": 1024,
      "create": "optional",
    },
    "operations": {
      "description": "User-specified operation hooks for this source.",
      "type": "object",
      "$ref": "/delphix-linked-source-operations.json",
      "create": "optional"
    },
    "mountBase" : {
      "type" : "string",
      "description" : "The base mount point to use for the NFS mounts.",
      "maxLength" : 87,
      "create" : "optional"
    },
    "loadBackupPath": {
      "type": "string",
      "description": "Source database backup location.",
      "maxLength": 1024,
      "required": true
    },
    "loadLocation": {
      "type": ["object", "null"],
      "description": "Backup location to use for loading backups from the
source.",
      "$ref": "/delphix-ase-backup-location.json",
      "create": "optional"
    },
    "dumpCredentials": {
      "type": ["object", "null"],
      "description": "The credential for the source DB user.",

```

```

    "$ref": "/delphix-password-credential.json",
    "create": "optional"
  },
  "sourceHostUser": {
    "type": "string",
    "description": "Information about the host OS user on the source to use
for linking.",
    "format": "objectReference",

      "create": "optional"
    }
  }
}
```

## API cookbook: EnvironmentUser

This API cookbook recipe describes how to configure your environment user using the Delphix Engine API.

```
{
  "root": "/resources/json/delphix/environment/user",
  "name": "EnvironmentUser",
  "description": "The representation of an environment user object.",
  "extends": {
    "$ref": "/delphix-user-object.json"
  },
  "nameParent": "environment",
  "properties": {
    "credential": {
      "type": "object",
      "$ref": "/delphix-credential.json",
      "description": "The credential for the environment user.",
      "create": "required",
      "update": "optional",
      "properties": {
        "type": {
          "type": "string",
          "description": "Object type.",
          "required": true,
          "format": "type",
          "default": "PasswordCredential"
        }
      }
    },
    "environment": {
      "type": "string",
      "description": "A reference to the associated environment.",
      "format": "objectReference",
      "referenceTo": "/delphix-source-environment.json",
      "create": "optional"
    },
    "groupId": {
      "type": "integer",
      "description": "Group ID of the user.",
      "create": "optional",
      "update": "optional",

  }
}

```

```
}  
}
```

## API cookbook: KerberosConfig

This API cookbook recipe describes how to configure Kerberos using the Delphix Engine API.

```
{
  name: "KerberosConfig",
  description: "Kerberos Client Configuration.",
  root: "/resources/json/delphix/service/kerberos",
  singleton: true,
  cliVisibility: [ "DOMAIN", "SYSTEM" ],
  extends: {
    $ref: "/delphix-user-object.json"
  },
  properties: {
    realm: {
      description: "Kerberos Realm name.",
      type: "string",
      create: "required",
      update: "optional"
    },
    kdcs: {
      description: "One of more KDC servers.",
      type: "array",
      create: "required",
      update: "optional",
      minItems: 1,
      items: {
        type: "object",
```

```
        $ref: "/delphix-kerberos-kdc.json"
    }
},
keytab: {
    description: "Kerberos keytab file data in base64 encoding.",
    type: "string",
    format: "password",
    create: "required",
    update: "optional"
},
principal: {
    description: "Kerberos principal name.",
    type: "string",
    create: "required",
    update: "optional"
},
enabled: {
    description: "Indicates whether kerberos has been configured or not.",
    type: "boolean"
}
},
read: {
    description: "Retrieve the specified KerberosConfig object.",

    return: {

        type: "object",

        $ref: "/delphix-kerberos-config.json"
    }
}
```

```
    }  
  },  
  update: {  
    description: "Update the specified KerberosConfig object.",  
  
    payload: {  
  
      type: "object",  
  
      $ref: "/delphix-kerberos-config.json"  
  
    }  
  },  
  rootOperations: {  
    reset: {  
      description: "Reset kerberos configuration and disable the feature.",  
      payload: {}  
    }  
  }  
}
```

## API cookbook: KerberosCredential

This API cookbook recipe describes how to configure Kerberos credentials using the Delphix Engine API.

```
{
  "name": "KerberosCredential",
  "description": "Kerberos based security credential.",
  "extends": {
    "$ref": "/delphix-credential.json"
  },
  "properties": {
  }
}
```

## API cookbook: KerberosKDC

This API cookbook recipe describes how to configure KerberosKDC using the Delphix Engine API.

```
{
  name: "KerberosKDC",
  description: "Kerberos Client Configuration.",
  extends: {
    $ref: "/delphix-typed-object.json"
  },
  properties: {
    hostname: {
      description: "KDC Server hostname.",
      type: "string",
      format: "host",
      create: "required",
      update: "optional"
    },
    port: {
      description: "KDC Server port number.",
      type: "integer",
      create: "required",
      update: "optional",
      minimum: 0,
      maximum: 65535,
      default: 88
    }
  }
}
```
